Peptonuria, accompanying cancer of the liver, however, requires a different explanation, and its almost invariable association with undoubted disease of the kind compels the theory that in health the liver has something to do with the conversion of peptone into albumen, and that in cancer this is interfered with. Such a view is sustained by the experiments of Plósz and Gyergyai, Hofmeister, and Seegen. Changes in the liver must be sufficiently great to influence this normal office. Should this be the case in other than cancerous disease, peptonuria may also occur, as is actually the case in acute yellow atrophy and phosphorous poisoning.

In nephritis, Pacanowski fails to confirm the statement of Senator, Petri, and Pœhl, that albuminuria and peptonuria coexist, having failed to find it in four cases of chronic and one of acute nephritis. In this he agrees with Maixner. Nor could he confirm the assertion of Fenomenow, that in urine containing numerous morphological elements, including pus and blood-corpuscles and tube-casts, peptone is present; nor that of Pœhl, that urine containing peptone, but no albumen, loses the former on becoming alkaline. Experiments with urine allowed to decompose, for the direct purpose of determining this, showed the continued presence of peptone, although the biuret reaction was weaker.

It will be seen, from the above quite full exposition of the subject, based upon the paper of Pacanowski, no diagnostic or prognostic value can as yet be associated with peptonuria, its presence being simply a part of the clinical history of the diseases with which it is associated. It will be seen, too, that it is a tolerably frequent condition; and the statement of Dr. George Johnson, already quoted in these pages, that it is rare, must be erroneous. The chief importance at present attaching to its study would seem to be not so much the determination of its presence as the avoiding of confounding the latter with albuminuria, an object which cannot be said, as yet, to be satisfactorily attained.

DIAGNOSIS OF THE POSITION OF THE HEAD IN LABOR BY TOUCHING AN EAR.

WHILE in the majority of cases of labor the obstetrician can make an accurate diagnosis of the position of the head by means of the sutures and fontanelles, there are some cases where he may be in doubt, or the landmarks referred to may fail in consequence of a large caput succedaneum. In the latter case it is usually recommended to introduce one or more fingers so as to touch the part of the head above the caput succedaneum where the sutures are unobscured by the swelling.

For the diagnosis of the position when great swelling of the presenting part, hiding the fontanelles and sutures, has occurred in consequence of protracted labor, DR. LOMER, of Hamburg, in a recent number of *Centralblatt für Gynäkologie*, recommends the use of the hand, especially when the forceps is to be applied, in order to feel an ear. The anterior and the posterior margin of the external ear differ so strikingly in shape, that if an ear can be felt—and if there be room for the introduction of the blades of the forceps there is room for this use of the hand—it is very easy to know the position of the head. He states that he has found this method so practical that in all his later forceps operations amounting to 109, he has resorted to it, having given up the attempt to locate sutures and fontanelles when the swelling referred to has occurred.

Lomer has revived an old practice. Smellie, for example, in the second edition of his *Midwifery*, London, 1752, says in his rules for applying the forceps: The position of the head is distinguished by feeling for one of the ears, the fore or smooth

Digitized by Google

part of which is towards the face of the child; if it cannot be ascertained by this mark, the hand and fingers must be pushed further up, to feel for the face, or back part of the neck; but, if the head cannot be traced, the observation must be taken from the *fontanelle*, or that part of the *cranium* where the lambdoidal suture crosses the end of the *sagittal suture*. It is also seen from this extract that Smellie ended the means of diagnosis with that with which most ob-tetricians to-day begin theirs.

The late Dr. McClintock, in one of his annotations found in the Sydenham Society's edition of Smellie, remarks. "I am sure there is often too much diffidence about using the *hand*, as pointed out by our author, for the purpose of acquainting ourselves with the condition of the pelvis, and the relative position occupied in it by the fœtal head."

ANTISEPTIC OBSTETRICS IN CITIES.

THE most important question in obstetrics at present is as to the use of antiseptics. Are these required in all cases of parturition, and if so, how are they to be used? May one rule be made for the direction of the obstetrician who practises in the country, and another for the city practitioner? The former will be very slow to subject a woman in labor or after labor, to antiseptic vaginal injections. Many a country physician has never had a case of puerperal septicæmia in his practice, or, at most, has only met with a few isolated cases of the disease, and it is natural for him, having got on so well without the precautions referred to, to reject their use in the future. While he may have reason founded upon his experience for this, his brother practitioner of the city has not so good an excuse for following his example. Bearing upon this question we desire to make brief reference to a work by DR. DEBACKER, upon the *Necessity of Antiseptic Accouchement in Populous Centres*, recently issued in Paris, of which we find a notice in the *Archives de Tocologie* for September.

Dr. Debacker states that if a woman takes baths in the latter part of pregnancy, she should add a solution of corrosive sublimate to the water, and also while taking the bath have a perforated tube placed in the vagina, so that the water may pass up to the neck of the womb. If she does not bathe, she ought to take a vaginal injection morning and evening of a solution of sulphate of copper, one part to one hundred. During labor a disinfectant vaginal injection is made, and phenic oil is used upon the finger before the latter is introduced into the vagina.

After the labor has ended and clots have been expelled, an irrigator with a vaginal canula well oiled and disinfected is used to throw into the vagina from half to a whole quart of a solution of sulphate of copper one part to one hundred; as the os uteri is now largely open, there is really a washing of the uterus thus made. The injections are repeated morning and evening.

Debacker holds that the antiseptic method ought to be universally adopted in all populous cities, that it alone offers almost a complete security in labor, and that should puerperal accidents occur, it is the remedy which, combined with those suggested by therapeutics, can alone effect a cure.

THE profession is again under obligations to the enlightened liberality of the National Government and to the intelligent zeal and indomitable industry of Surgeon Billings for the sixth volume of the *Index Catalogue of the Library of the Surgeon-General's Office*. This volume, which has just been issued, contains 1051 double-column pages, extending from "Heostic" to "Insfeldt," and includes 7900 author-titles and 49,880 subject-titles, and embraces some very large subjects; for instance "hernia" occupies 84 pages, "hospitals" almost 100 pages, "hydrophobia" 31 pages, "hygiene" 117 pages, and "insane" and "insanity" 57 pages.

The value of this work in the study of the alleviation of human suffering is simply incalculable, and it behooves the profession and the public to see that no other duties shall be imposed upon Dr. Billings which will interfere with his giving his close personal supervision, which is necessary to the accuracy of the work, to the completion of this great undertaking, the publication of which redounds so highly to the honor of the Nation.

REVIEWS.

MANUAL OF PHYSIOLOGY, A TEXT-BOOK FOR STUDENTS OF MEDICINE. By GERALD F. YEO, M.D., F.R.C.S., Professor of Physiology in King's College, London, etc. With 301 engravings. Pp. 749. Philadelphia: Blakiston Son & Co., 1884.

THE rapid development of physiological science has rendered such standard works as that of Carpenter, so bulky, that an imperative demand for manuals of more moderate size has arisen, not only among students, but also among practitioners who desire to keep themselves thoroughly *au courant* with the wonderful advances recently made in this department of biology. To meet such a want Dr. Yeo has prepared this excellent text-book, which for a work of its limited scope is entitled to unqualified praise. The author has judiciously endeavored to avoid the introduction of theories which are as yet unestablished, and has omitted such details of methods as are unimportant for the younger class of students. Much space is saved by restricting statements to the mere facts, without any history of how our knowledge has been obtained, or to whom we owe the great debt of discovery in regard to them. Dr. Yeo's practical experience as a teacher and examiner of students, has taught, and so well taught him what par-

Digitized by Google

ticular subjects are difficult of comprehension by the average pupil, that these questions are elucidated with especial care, and yet the error of too elaborate explanation, at the expense of undue curtailment of other important departments of the science, is skilfully guarded against. Indeed, distinguishing characteristics of the work are perspicuity without diffuseness, and condensation without lack of precision or the omission of essential truths. The woodcuts are numerous and of excellent quality, those illustrating the admirable chapter devoted to reproduction and the development of the embryo, being especially valuable to a novice in this fascinating department of natural science.

A HANDBOOK OF THE DISEASES OF THE LIVER, BILIARY PASSAGES, AND PORTAL VEIN. By HENRY R. RUCKLEY, Licentiate of the Royal College of Physicians, Edinburgh. 8vo. pp. 221. High Wycombe, F. Westfield. London: W. Kent & Co.

THIS work, the author tells us, was suggested by his own necessity; for after reading all the modern works on the subject, he felt that there was wanting a small, handy manual suitable for the general practitioner and student. We sincerely trust that active professional duty at High Wycombe will prevent his reading all the modern works on any other subject, lest a similar compulsion should seize him, and result in the production of another such dull, toneless compilation as the present volume.

SOCIETY PROCEEDINGS.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Thirty-fourth Annual Meeting, held at Ann Arbor, Michigan, August 26–31, 1885.

(Specially reported for THE MEDICAL NEWS.)

(Concluded from page 306)

DR. H. G. BEYER, of Washington, presented the following

BIOLOGICAL DEDUCTIONS FROM A COMPARATIVE STUDY OF THE INFLUENCE OF COCAINE AND ATROPINE ON THE ORGANS OF CIRCULATION.

The study of action of drugs on the animal organism has received such a step-motherly treatment at hands of scientists' investigations, that it is fair to make the general statement that there are very few drugs that will not admit of a reinvestigation by our present improved scientific methods. I do not propose, however, to go into the action of these drugs, and I shall briefly speak of the purely biological results which these experiments allow me to make.

These deductions are considered of sufficient importance to be brought before this Association, for the reason that they touch upon the complex but deeply interesting problem of the innervation of the vertebrate heart. The heart, histologically considered, is a compound organ, consisting of musculator, nervous, and connective tissue. No study of the action of any drug upon the heart can be considered complete, unless the nature of the action of such a drug upon each of these different elements composing the heart is clearly made out. The extreme difficulty of this problem, however, must be apparent to you, even without my attempting to go into a review of the historical details of the controversy that exists between the best physiologists with regard to the action upon the heart of even the best-known drugs.

With reference to the action of atropine upon the heart, it is the opinion of Schmiedeberg, Harnack, and others, that it produces paralysis of the vagus endings within the heart, thus causing acceleration and augmentation in its action; muscarine, in their opinion, stimulates these same nerve-endings, thus producing diastolic arrest.

Bowditch, as long ago as 1871, and more recently, also, Gaskell and Ransom, have come to the conclusion that atropine stimulates the muscular substance, and that the augmentation it produces in the heart's action is due to that influence, and not to a paralysis of the vagus endings.

Recently Amalie Glause, in her inaugural thesis, gives an account of some experiments, made in the laboratory of Professor Luchsinger at Berne, which tend to prove almost conclusively that muscarine paralyzes the heart muscle, instead of stimulating the vagus endings, and that, therefore, the diastolic arrest it produces is due to its paralyzing influence on cardiac muscle, rather than to its stimulating influence on the vagus endings. In other words, the antagonistic action of atropine and muscarine with reference to the heart according to Schmiedeberg, Harnack, and others, is a purely nervous phenomenon; while, according to more recent and equally good observers, it is a purely muscular phenomenon.

From our last winter's work on the action of cocaine, atropine, and muscarine on the heart, we are enabled to add some further proof to the muscular nature of the action of these drugs on the heart, at the same time we may perhaps succeed in indirectly showing that atropine and cocaine, instead of paralyzing the vagus endings, slightly stimulate them.

Upon the first admission of atropinized blood into the isolated heart of the frog or terrapin, the heart-muscle preëminently manifests the action of some powerful stimulant. After a while, however, there arrives a stage of muscular exhaustion from over-stimulation, and, at the same time, there appears a peculiar dissociation of rhythm between auricles and ventricle, the auricles contracting two or three times to the ventricle once, quite independent of each other.

The dose of the drug may be so graduated that this peculiar rhythm can be kept up for any desired length of time, and, after the heart has been allowed to recover under normal blood, it can be reproduced many times during the course of one single experiment.

How are we, now, to explain this singular phenomenon? Last year, in one of the Paris hospitals, under the service of Prof. Boudet, a patient came under observation who had a radial pulse of only 21 beats per minute, the auricles beating at the rate of 63 per minute. Prof. Chauveau took a sphygmographic tracing of this patient, and went to work investigating the pathogeny of this condition. By dividing one of the pneumogastrics in a dog (?) he obtained some dissociation of rhythm, but, by slightly stimulating with a galvanic current the left pneumogastric, he obtained a sphygmographic tracing which was identical with that taken from his

Digitized by Google

patient. If these observations are correct, which we have no apparent good reasons to doubt, I think that it is not at all improbable that the dissociation in rhythm which we have observed as produced by atropine is due to a slight stimulating action which this drug exerts on the vagus endings, and which becomes apparent after the muscular substance at the heart has begun to show signs of exhaustion.

Now, cocaine produces exactly the same dissociation of rhythm, but, unlike atropine, cocaine produces it almost at once, for the latter does not possess any stimulating properties on muscular tissue. The sympathetic nerve endings are equally stimulated by these two drugs, since the work done by the heart, during this stage of comparative muscular exhaustion and lowered ventricular rhythm, is still much greater than under normal conditions.

If muscarine produces cardiac diastolic arrest through its paralyzing influence on the muscular substance, and atropine and cocaine affect the heart in every respect alike, except that cocaine does not stimulate the muscular substance, then muscarine must produce diastolic arrest in the cocainized heart, which, indeed, it invariably does. And here we have another proof of the muscular nature of the atropine—muscarine—antagonism as manifested by the heart.

These experiments alone would, of course, not be sufficient to prove decisively, but, taken in conjunction with the experiments briefly alluded to above, they form a sort of crucial test.

We may now, with regard to the action of these drugs on the heart, formulate our conclusions as follows, viz.: Muscarine paralyzes the cardiac muscle; atropine stimulates the same. Atropine, furthermore, has a slight stimulating effect upon the vagus endings, and also on the endings of the accelerator or augmentor nerves of the heart. Cocaine affects the nerve-endings within the heart in the same manner as atropine does, but, unlike the latter, has no stimulating action on its muscular substance.

DR. C. S. MINOT, of Boston, read a paper

ON THE STRUCTURE OF THE HUMAN PLACENTA.

There are many clashing opinions about the physiology of the placenta. It is common to assume that there is intimate union between tissues of placenta and of the mother, and that the embryo derives nourishment from the mother through this close union. By the use of celloidine, we are able to hold substances in position and to make sections for microscopic examination, thus securing valuable possibilities for studying the placenta beyond previous means.

The structure of the placenta is remarkable, because of the great irregularity of the shape of its villi. I have made a large number of sections, some of them in 500 or 600 parts, which all fall apart when the celloidine is dissolved. Prof. Langhaus has done good work in investigating these matters.

By the third week of gestation the placenta begins to develop; villi grow out from the ovum and touch the maternal tissue. The development of one side is much more rapid than that of the other. The only contact between the placenta and the maternal tissue takes place at the tips of these villi. We are unable to say that we find here a true epithelium, but rather, apparently, a syncytial layer.

The human placenta consists of

1. The amniotic epithelium; 2. Connective tissue; 3. Stroma of chorion; 4. Cellular layer; 5. Fibroid layer; 6. Villi; 7. Chorionic epithelium; 8. Serotina.

There is no intergrowing of the maternal and fœtal tissues. The placenta is mainly fœtal, and the intervillous spaces are bounded only by fœtal tissue. The fœtus, then, is nourished by a uterine milk secreted in a manner not dissimilar to that of the milk in the breasts; and it is only partly nourished directly from the circulation of the blood of the parent.

PROF. GAGE stated that this theory simplified the problem of nutrition, but complicated that of respiration.

DR. MINOT replied that the fœtus needed not much oxygenation of the blood, not having any work to do but to sustain its own life and growth, and blood of the fœtus, both venous and arterial, is usually red, showing full oxygenation.

DR. MINOT also read a paper on

THE EVOLUTION OF THE LUNGS.

Heretofore no acceptable theory of the origin and evolution of the lungs has been promulgated. It has generally been believed that they are modified air sacs, appearing first in fishes, and developing into lungs in higher animals.

Lungs always arise out of the intestine of the embryo. The air sac of fishes arises out of the dorsal, while the lungs arise out of the ventral side of the embryo. He believes the lungs to be modified gills. They arise as pouches from the walls of the pharynx. In the embryo of mammals gill arches arise and develop on the ventral side. The pouch soon extends down and forms what all embryologists recognize as the beginning of the lungs. If we see a succession of pouches lying alongside each other, and formed in the same way, we homologize them, notwithstanding the different functions they subserve in the adult. The ear cavities, and the thyroid and thymus glands, as well as the lungs, arise from these gill pouches.

This paper was only advanced as a preliminary hypothesis.

PROF. COPE discussed the paper, and suggested that the present hypothesis of evolution may be sustained on the theory that in the embryology of fishes the original method of evolution may have been modified, as the germs of *polyparus* still show development of air sacs from the dorsal side.

DR. C. S. MINOT then read a paper on the

MORPHOLOGY OF THE SUPRARENAL CAPSULES.

Balfour and his scholars have maintained the theory of the double origin of the suprarenals. Examination of the human fœtal capsule renders it difficult to accept this view, since the whole structure is similar throughout. There are masses and cords of cells which are in radial lines externally, but more irregular internally; but the cells of the cortex and medulla both present, in a six months' fœtus, a similar and very remarkable appearance, so that it is difficult to admit that they are distinct tissues of two distinct origins. The histological character of the parenchyma was described and illustrated.

Digitized by Google

DR. MINOT also called attention to

A NEW MEMBRANE OF THE HUMAN SKIN.

In the human fœtus there is a layer of large cells outside the horny layer, and entirely distinct from it. This layer is homologous with the epithelium of the sauropsida, and covers also the hairs and glands. Its presence probably accounts for the retention of the sebaceous secretions to form the *vernix caseosa*.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, September 3, 1885.

THE PRESIDENT, B. F. BAER, M.D., IN THE CHAIR.

DR. B. F. BAER read the following report of a case of

OVARIAN CYSTOMA COMPLICATED WITH PERITONITIS AND PHLEGMASIA ALBA DOLENS; DOUBLE OVARIOTOMY.

Mrs. M., æt. 31, has been a widow nine years, she had one child ten years ago, and had enjoyed good health until about three years before I saw her. At that time she observed that her abdomen was increasing in size. This gradually progressed for eighteen months, when she was large enough to attract the attention of her neighbors. After this the growth remained almost stationary, and did not affect her general health until the latter part of March of the present year, when she was suddenly seized with pain in the left iliac region. The pain was acute and radiating in character, extending principally down the anterior portion of the left thigh. She attributed the attack to an unusual exertion. Although she made an effort to continue her avocation, —that of seamstress—she was compelled to give up and send for her physician, my friend, Dr. John R. Haney, of Camden.

When Dr. Haney first saw her, her abdomen was very tender over its entire surface, purple from congestion, greatly distended and tympanitic in its upper but dull in its lower portion. She was suffering great pain and had constant nausea and vomiting, her skin was hot, pulse 120, and temperature 103°. From the history, symptoms, and physical signs elicited, the doctor diagnosticated ovarian cystoma with supervening peritonitis. He administered quinia per rectum and morphia hypodermatically, together with counter-irritation over the abdomen. Within a week the patient appeared to be better, when, through the kindness of Dr. Haney, I first saw her. The tympanites had disappeared, and the pain was not so severe, but the abdomen was still very tender on pressure, especially in the left iliac and right umbilical regions; her features were drawn and flushed, and presented an anxious expression; her tongue was dry and heavily coated, pulse quick, and temperature 102°. She lay quietly in the dorsal position with her thighs flexed. The abdomen was as large as at full term of gestation, and was projecting. It was dull on percussion everywhere except along the line of the colon, and in the epigastrium there was evident fluctuation. The uterus was retroverted, not freely mobile, and very tender on pressure on the left side. Above and upon it could be felt the lower border of the circumscribed growth which occupied the abdominal cavity. I fully agreed with Dr. Haney's diagnosis of ovarian cyst complicated by peritonitis. As she seemed to be somewhat better, I advised a continuance of the treatment as previously pursued, with the hope of obviating the necessity of ovariotomy during the unfavorable condition in which she then was.

The peritonitis continued to improve slowly, but a new trouble presented itself in a very painful swelling of the left lower extremity. This continued until the limb was greatly increased in size. Its temperature was much higher than that of its fellow, which seemed to be in a normal condition. She now required large doses of morphia to relieve her pain, and she was losing flesh and strength. She still had nausea and took almost no nourishment. Her temperature and pulse had again risen to the highest point noted. Both she and her friends were willing and anxious that we should do something more radical than simply to wait for a more favorable condition for operating if we deemed it proper. I believed from the symptoms and physical signs, that the inflammatory action was external to the cyst and not within it, and for that reason decided to wait for a subsidence of the acute symptoms, which I rather confidently expected. At the same time I held myself in readiness to operate at once should the patient not improve or become worse. The next day she showed signs of slight improvement. Treatment, both local and general, continued. The acute symptoms gradually subsided to those of a subacute condition. The temperature had decreased to 101°, pulse 100 but weak. She was still unable to retain food and was extremely weak. I advised further delay, but she did not improve much after this, her temperature and pulse remaining about the same as that noted above. Her stomach had regained its power, to a slight degree, to retain and digest liquid food.

She had now been confined to her bed more than two months. Her left leg was powerless. There had not been the slightest improvement during the two previous weeks. We therefore decided to remove the tumor.

Operation.—June 19, 1885, assisted by Drs. J. K. Haney, W. H. Davis, and H. M. Christian, and in the presence of a section of the class from the Polyclinic, I made an incision three inches in length down to the peritoneum, and then checked the hemorrhage, which was free, with clamp forceps. I next very carefully incised the peritoneum, and found, as I had expected, that it was closely united to the cyst wall. These adhesions of cyst to peritoneum were universal, and it required careful and patient manipulation to separate them. The parts were exceedingly vascular and hemorrhage was profuse. After separating it as far as possible, I tapped the cyst and allowed the contents, which were semi-liquid and chocolate-colored, to drain away. I next closed the puncture made by the trocar, and then completed the separation of the cyst from its adhesions and removed it. As there was a very general and free oozing of blood from the broken vessels, I introduced a number of large flat sponges and spread them over the bleeding surface. An assistant now made firm pressure upon the external surface of the abdominal walls whilst I ligated the pedicle and removed the tumor. The cyst developed in the left ovary and the pedicle was slender, not unusually vascular, and of good length. The right ovary was diseased, contained a number of

Digitized by Google

small cysts, and was double the normal size. I removed it also. Examination now showed that the hemorrhage had almost ceased, but there were still a number of points from which blood flowed. The peritoneum was intensely injected and I disliked very much to pick up bleeding points for fear of making the hemorrhage worse. I therefore reapplied a large flat sponge, and had firm pressure again made from without whilst I proceeded to place the sutures for the closure of the incision. I then removed the sponge and found very little blood upon it. I replaced it by a long, narrow strip of sponge which I allowed to project from the lower angle of the wound and then again cleansed Douglas's cul-de-sac and other dependent portions of the peritoneal cavity, after which I quickly tied the sutures from above downwards removing the long sponge through the lower angle of the wound before I had encroached so closely upon it as to compress it in its removal. It was only slightly stained. I quickly applied the external dressing, making an unusual amount of pressure by cotton and bandage. The operation was finished, but the patient bore it badly. Her extremities were cold and purple, her face livid, and pulse very weak. Stimulants hypodermically, and the application of external heat, which were begun during the operation, were continued after she was returned to bed. She remained in an almost collapsed state for many hours, but gradually reacted, and the next morning was in a fair condition. Her temperature was lower than it had been for weeks, pulse 112 but weak, stomach quiet, no pain, no tympany. She had taken an occasional small piece of ice, but nothing else except the morphia, since the operation.

21st.—Temp. 102°; pulse 120. Slight pain and tenderness in left iliac region. She had been very weak and faint during the night, for which brandy had been administered in repeated small doses. The swelling and pain in the limb had diminished; she had not vomited since the operation, and felt hungry. Ordered a teaspoonful of milk every second hour.

22d.—Comfortable and doing well. Temp. 99⅘°; pulse 90, and strong. Slight metrostaxis. Passed flatus per rectum. Milk increased to a tablespoonful, and retained.

24th.—Temp. 99°; pulse 85. General condition greatly improved. No pain; no tympany. Examined wound and found it united throughout; removed sutures.

25th.—Doing well, and is bright and cheerful. She took nearly a quart of milk during the last twenty-four hours, and digested it.

30th.—She has been gradually improving. Temp. normal; pulse 95. Bowels moved to-day. She is taking solid food, and expresses herself as feeling quite well. Limb improving. She can now move it.

July 12.—Sat up to-day for the first time, the twenty-second after the operation.

August 30.—A note received from Dr. Haney to-day informs me that Mrs. M. is going about attending to some of her duties, but that she has not yet regained her strength fully, and that her limb is still weak.

The recovery of this woman under the forlorn circumstances just narrated is certainly a great triumph for our art; but the case serves a better purpose in forcibly illustrating the danger of deferring operative interference in ovarian cystoma simply because the patient is comfortable and suffering no inconvenience from the presence of the tumor. The subject of an ovarian tumor is in constant danger of injury from slight causes, which may produce such changes in the tumor as to render what might have been a simple and safe operation, one of extreme hazard. This had been a simple, slow-growing cyst, and had not markedly affected the health during its three years of existence; yet it suddenly became inflamed, and the patient narrowly escaped death as a result. The case furnishes a strong argument in favor of operation as soon as the disease is diagnosticated. Of course there are qualifications, and each case must be decided on its own merits; but the rule that an ovarian tumor should be removed as soon as it is known to exist is the only safe one to follow.

As a striking contrast to the case just related, and to show the value of the principle enunciated, I will report the following case of

POLYCYSTIC OVARIAN TUMOR: DOUBLE OVARIOTOMY.

A. R. was sent to me August 5, 1885. She was nineteen years of age; single. Puberty was established at sixteen, and she had menstruated regularly until six months previously. She then, without cause so far as she knew, began to flow more freely at her periods, and they continued longer. About the same time she noticed a small lump in the right iliac region. This increased in size, so that soon the entire hypogastrium was distended, and when I first saw her she was as large as at the eighth month of gestation. Her face showed marked signs of emaciation and pallor, and the drawn, anxious expression of ovarian cystic disease. She was then having a profuse metrorrhagia every two weeks. She had not suffered any pain, and up to within a few weeks very little inconvenience, except from the frequent metrorrhagia. During the last month, however, her health had been failing. She had lost flesh, had a weak, languid feeling, and suffered much from the weight of the growth. Physical examination in the dorsal position revealed a projecting, slightly irregular abdomen, larger on the right side, dull on percussion over the entire anterior surface, but resonant along the line of the colon. Palpation showed imperfect fluctuation and several firm, irregular masses within the abdominal cavity. The vagina was virginal, the cervix uteri was pointing forwards, the body of the uterus retroverted, the whole organ enlarged and soft. It was only slightly movable independently of the tumor. The sound gave a measurement of three inches.

I diagnosticated polycystic disease of the right ovary, and advised immediate operation.

Six days afterward, on August 11th, she entered my private hospital; and on the 13th I operated, with the assistance of Drs. H. M. Christian and J. N. Richards. I made an incision two and a half inches in length, and came upon the surface of the tumor, which presented the white, glistening, nacreous appearance especially common to thick-walled polycysts. Tapped with Hodge's trocar. The contents were so thick that they flowed very slowly, and it was necessary to puncture several smaller cysts, which was done without removing the instrument. Even then the mass did not collapse, much because of a large number of young or child cysts. After closing the puncture, I enlarged the incision

Digitized by Google

to three inches, but I had considerable difficulty in removing the tumor. It was necessary to make firm traction with rotatory movements whilst Dr. Christian exerted a counter-force and pressure through the abdominal walls. Fully ten minutes were occupied in delivering the tumor after it was tapped, but I was rewarded with an incision that looked so small that it seemed almost incredible that this large mass had passed through it. There had not been a single adhesion, but the pedicle was short, thick, and vascular. I tied it with Tait's Staffordshire knot, cut the tumor away, and dropped the stump. The tissues of the left ovary were found to be entirely disorganized and degenerated into a cyst as large as a walnut. This I also removed. The uterus presented a very vascular appearance and was somewhat enlarged. After assuring myself that the peritoneal cavity was entirely free from any foreign matter, I closed the incision, dressed the wound, and returned the patient to bed. Temperature normal, pulse 96; no pain, but as she felt a little sore and restless a quarter of a grain of morphine was given hypodermatically; small pieces of ice to relieve thirst.

14th.—8 A. M., temperature 99°; pulse 84; has passed a good night. At 1 P. M., twenty-six hours after the operation, milk in teaspoonful doses was allowed; water when she desired it.

15th.—Metrostaxis began this morning.

18th.—Union complete; removed sutures. Her recovery was uninterrupted. She sat up for a few minutes on the eleventh day, and went home, eight miles, in a carriage on the eighteenth day after the operation. To-day she sent a request to be permitted to go out, because she is feeling so well. Certainly nothing could have been gained by procrastination in this case.

DR. GOODELL congratulated Dr. Baer on the good results obtained in such a serious case as that first reported. Great care in the asepsis of these cases should be observed. In one of his cases of septicæmia, after complete union had been secured, and the stitches had been removed, and after the patient was up, an abscess was observed forming in the line of union and was very persistent. Finally, after careful search, a ligature which had been tied around the pedicle of one of the ovarian cysts was found and removed. Subsequently the other appeared, and after its removal the abscess healed.

He did not like to remove the stitches so early as Dr. Baer removed them; and he recalled a case in which Dr. Baer had assisted him. The operation was performed on December 5th. Convalescence was rapid and the patient was so impatient to be home on Christmas, that she could not be restrained, and on the nineteenth day after the operation she took the cars for home. The train was derailed and the jolting caused the cicatrix to open. The physician who was called in closed it immediately, and the patient recovered. In another case a cough caused the wound to burst open and reveal the bowels after the stitches had been removed. This patient also recovered. For these reasons he never removed the stitches before the eighth day, and not until the bowels had been opened.

Dr. Goodell inquired of Dr. Baer his method of closing the opening in the cyst after it had been tapped preparatory to its removal from the abdominal cavity. Does he employ pressure forceps? What method of dressing the abdominal wound?

DR. BAER closes the cyst puncture with Wells's clamp forceps when the cyst wall is strong enough. In some cases he stitches up the opening or ties a string below it when the cyst walls are loose and soft. He closes the external wound, as he had been taught by Dr. Goodell, with silk sutures and dresses it with salicylated or absorbent cotton, adhesive strips to hold the cotton in place and take the strain off from the stitches, and over all a bandage. He removes the sutures on the fourth or fifth day, in order to avoid the danger of pus forming in the suture tracks, as has sometimes occurred when he has allowed them to remain as long as eight days.

DR. GOODELL exhibited his improved

UTERINE DILATOR.

He said that the main difficulty in the operation for the rapid dilatation of the cervical canal lies in the liability of the blades of the instrument to slip out. This he had, in a great measure, overcome by having shallow grooves cut into them. Into these grooves the tissues sank, and the resulting friction keeps the instrument in place.

Since he had called the attention of the Society to his instrument, not quite a year ago, he had performed the operation forty-one times for dysmenorrhœa and sterility, making in all, two hundred and nine such cases. In not a single instance had dangerous symptoms followed, and the average of success was a very large one. He had become firmly convinced that for dysmenorrhea and sterility the operation of rapid dilatation of the cervical canal would, except in some very rare cases of stenosis of the os externum, wholly supersede the cutting operation, the use of tents, or the slow dilatation by any means whatever. For, by the former, not only is the measure of success far greater, but the danger from inflammation is very much less. He dilated the parts from three-quarters of an inch to one inch and a quarter, as measured by the register in the handles, watching the cervix carefully to see what strain it could bear. His instrument could be opened to the width of one and a half inches, but he resorted to that extreme divergence only when wishing to introduce his finger for diagnostic purposes. This he could not ordinarily do unless the parts were relaxed from hemorrhage. Usually, however, when suspecting the existence of a polypus, he did not find it needful to pass in his finger, for after a moderate dilatation he introduced a fenestrated forceps and opened it at haphazard. In this manner he has repeatedly caught and twisted off a polypus without knowing it was present, the subsequent removal of the growth through the os uteri being the most difficult part of the operation.

DR. BAER was strongly impressed by the case of a lady whom he had delivered to-day, as to the advisability of entirely giving up division of the cervix. A year and a half ago he had slit up the cervix posteriorly, and to-day he felt very anxious, during the first stage of labor, as to the probability of laceration of the uterus, starting from the seat of the former operation. The anterior lip was very long, coming down under the pubis, and the posterior lip could not be felt. The case will be reported fully. When the uterus contains a

Digitized by Google

polypus, the continued hemorrhages reduce the contractility, and a single dilatation will sometimes enlarge the os sufficiently to admit the finger or forceps; but, if the uterus is healthy, it contracts immediately after the withdrawal of the dilator. He could not recall an instance of inflammation following rapid dilatation. Sterility of long standing is seldom cured by dilatation or any other means.

DR. C. M. WILSON had seen recently in the practice of Dr. Ellwood Wilson a uterus, the cervix of which had been divided bilaterally some years ago. The operation had resulted in the development of the symptoms peculiar to a bad laceration of the cervix, with ectropion. Trachelorrhaphy was performed by Dr. Agnew, with complete relief to the patient. Dr. Wilson mentioned this case to call attention to the change in opinion and practice since Emmet proposed his operation.

DR. LONGAKER inquired as to the prevention of slipping of the dilator, and called attention to the original method of pressure over the fundus of the uterus.

DR. J. G. ALLEN has performed rapid dilatation more than seventy-five times, and has never seen any bad results from the operation. The blades of his instrument diverge as they separate, and there is then no disposition to slip out. The blades are more curved than in Dr. Goodell's instrument; he thinks that an advantage in holding the instrument in place. The handles are turned up so as not to touch the bed or table.

DR. GOODELL prefers the slight curve, so that in flexion of the uterus he can introduce the dilator with its curve reversed to the bend in the womb, and by opening the dilator in that position rectify the flexion of the organ. He prefers parallelism of the blades, because the stenosis of the cervix is greatest at the external os, and there is no need for dilatations above the internal os. He considers it dangerous to press the fundus of the uterus down while using the dilator, for fear of wounding or even penetrating the tissues, and he uses a strong tenaculum to hold the organ; but, since he had got Mr. Gemrig to roughen the blades by grooves, he had not been annoyed by the slipping of the instrument. He rarely finds it necessary to separate the blades more than one inch, but he sometimes does so to the extent of one and a half inches, especially when he wishes to introduce his finger into the uterine cavity.

DR. GOODELL exhibited two specimens of

PAROVARIAN CYSTS.

In each case the cyst was so detached from the ovary that the former could have been taken away without injury to the ovary. He was greatly tempted to practise conservative surgery in these cases, and leave the ovaries untouched; but, on account of apparently incipient cystic degeneration, they, also, were included in the ligature and removed. Both these cases were operated on in his private hospital, and both had recovered.

In his experience, the removal of parovarian or of broad ligament cysts was one of the most successful of operations. Out of a large number which he had performed, he could recall but a single fatal case, and in that the result seemed hardly due to the operation. The lady lived in a distant city, and he did not see her after the operation, which was a very easy one. At the end of a week the bowels were moved, the stitches removed, and everything gave promise of an unusually prompt convalescence. On the twelfth day, however, she was seized with uncontrollable vomiting, and she died on the seventeenth day. Six months previously she had had an analogous attack of vomiting, from which she barely escaped with her life. Thus far this year he had had eighteen ovariotomies, and this was the only fatal case among them.

DR. MONTGOMERY wished to ascertain the opinion of the Society as to the advisability of removing the second ovary when, in an operation for the removal of an ovarian cyst, the other ovary was found to be slightly diseased. In his first ovariotomy, performed in 1879, the second ovary was found to contain numerous small cysts; it was not removed, and the patient has since been twice pregnant, and there has been no appearance of another tumor, nor any symptoms referable to the remaining ovary. If the climacteric has been passed, there would be no question about it.

DR. BAER inquired whether tapping ever cured parovarian cysts. It was formerly reported as a means of cure. Do they always return after tapping? Would Dr. Goodell recommend tapping in undoubted parovarian cyst? He himself felt strongly inclined toward abdominal section in all cases. He thinks the second ovary should be removed when it is not healthy, as the idea of a second operation is very depressing to a patient.

DR. MONTGOMERY knew of one instance of parovarian cyst which had been tapped and had refilled seven times. It was finally removed by him by pulling out the cyst, as, on opening the abdomen, he found the tumor universally adherent. Only one ligature was required, viz., on the stump of an enlarged ovary, which bulged prominently into the cyst cavity.

DR. J. G. ALLEN considered that as an ovary somewhat diseased may give rise to a pregnancy, it should be left. We know too little about the probability of the development of small cysts into large ones. Until we have certain data on the subject, it must be considered a case of lack of information and knowledge.

DR. PARISH was in accord with Dr. Allen as to the want of knowledge. He has seen diseased ovaries containing numerous small cysts in many autopsies, and there had been no symptom during life to excite a suspicion of their existence. The existence of minute cysts cannot be considered as proving any liability to the production of large ones. If the second ovary contained a cyst as large as a partridge's egg, he would remove it; but if numerous cysts, as small as split peas, were present, he would not. The possibility of conception should be considered, as well as that of a cyst.

DR. GOODELL acknowledged the truth of the points made by Drs. Allen and Parish, and he believed that he had repeatedly removed the second ovary unnecessarily; yet the history of his own ovariotomies shows a return of the disease in the remaining ovary in about two per cent., and he thought he erred on the safe and right side. The social condition of the patient would always have a great weight with him. If an heir were wanted, or the patient were young, he would leave a suspicious-looking ovary, or try to remove the diseased portion of it. But in the majority of his cases, where there was any doubt, he removed the ovary. Of course, under such a rule, he must remove ovaries which might

Digitized by Google

never give any trouble in the future. But the mental agony of women, when informed that the operation must be performed a second time upon them: and, on the other hand, the great joy and satisfaction of patients when assured, after the close of an operation, that both ovaries had been removed, have determined him that, other things being equal, it is better to remove the second ovary. As to the cure of parovarian cysts by tapping, his own experience is not sufficient yet to decide absolutely. He would advise the radical operation; but if the patient, after understanding the liability of return, wishes it, he would tap, as there is but little danger from tapping such cysts. A patient was tapped by Dr. Atlee, some twenty years ago; five years afterwards the cyst filled, and was tapped by Dr. Goodell. It then partly refilled, and so remained for a long while. The fluid then was gradually absorbed and never returned. He has had beside this two cases which he tapped, one four years ago, and the other three years ago, and there has been no return whatever of the fluid. On the other hand, he has had two or three cases in which the cyst burst spontaneously several times and yet refilled invariably. The rupture was followed immediately by some collapse, and pain and later by an excessive secretion of urine, with complete subsidence of the tumor. He had also heard of several cases of rupture, but, so far as he had learned the history of such cases, the cyst has always returned. The reports of the cure of ovarian cysts by tapping and injection of tincture of iodine must be true only of parovarian cysts.

DR. HARRIS knew of a case of parovarian cyst in which fourteen years had elapsed between the tapping and the subsequent refilling.

(*To be concluded.*)

NEWS ITEMS.

MONTREAL.

(*From our Special Correspondent.*)

SMALLPOX EPIDEMIC.—According to Dr. LaRocque's report recently published, there were, during the last three months, 315 deaths from smallpox; of these 270 were French Roman-Catholics, 27 Irish Roman-Catholics, and 18 English-speaking Protestants. Nearly three-fourths of the deaths amongst the French were children under five years of age,—unvaccinated, of course.

The Provincial Board of Health recently appointed by the Quebec Provincial Government, meets three times a week, but as yet has done little more. Nothing is said about compulsory vaccination. Isolation is advocated, as well as cleanliness, but apparently there is not backbone enough in the Board even to propose such an unpopular procedure as compulsory vaccination. Until compulsory vaccination is enforced, it will be vain to expect to control the epidemic. Certainly, the smallpox will not be banished by more thorough scavenging and the issuing of verbose circulars *advising* the public to isolate cases of smallpox, and to avail themselves of the privileges of vaccination, Six public vaccinators are scarcely enough to vaccinate a city of two hundred thousand inhabitants. Supposing each were to vaccinate 200 a day, it would take nearly six months to go through the city. Last week one of the public vaccinators, making house to house visitations in the French part of the city, could only persuade three people to submit to vaccination.

MCGILL MEDICAL SCHOOL.—The new medical building in connection with McGill University is rapidly approaching completion. It is intended to open it formally and publicly some time in October. The building is a most commodious one; new chemical, physiological, histological, and pathological laboratories have been added, and the dissecting room, library, and museum have been much enlarged. There are also two new lecture rooms, each capable of comfortably seating nearly 300 students.

THE NEW ORGANIZATION OF THE INTERNATIONAL MEDICAL CONGRESS—For the information of the profession, we herewith give a complete list of the officers of the proposed Congress as appointed by the Chicago Committee, and revised at the late New York meeting, the names of those who, so far as is publicly known, have declined to accept office under the new Committee, being printed in italics.

PRESIDENT.—Austin Flint, M.D., of New York.

VICE PRESIDENTS.—Drs. H. F. Campbell, of Augusta, Ga.; R. P. Howard, of Montreal; T. G. Richardson, of New Orleans; *A. Stillé*, of Philadelphia; W. O. Baldwin, of Montgomery, Ala.; *H. H. Skillman*, of Lexington, Ky.; L. A. Sayre, of New York; W. W. Dawson, of Cincinnati; J. M. Toner, of Washington; Wm. Brodie, of Detroit; *John L. Atlee*, of Lancaster, Pa.; *Oliver Wendell Holmes*, of Boston; H. I. Bowditch, of Boston; and E. M. Moore, of Rochester.

SECRETARY GENERAL.—Drs. *John H. Packard*, of Philadelphia; N. S. Davis, of Chicago.

TREASURER.—Dr. E. S. F. Arnold, of New York.

CHAIRMAN OF FINANCE COMMITTEE.—F. S. Dennis, of New York.

GENERAL COMMITTEE.—Drs. Beverly Cole, of San Francisco, Chairman; J. S. Lynch, of Baltimore, Vice-Chairman; John V. Shoemaker, of Philadelphia, Secretary; Henry F. Campbell, of Georgia; *John S. Billings*, U. S. A.; *John M. Browne*, U. S. N.; *George J. Engelmann*, of St Louis; *I. Minis Hays*, of Philadelphia; *Christopher Johnston*, of Baltimore; Lewis A. Sayre, of New York; G. A. Ketchum, of Mobile; D. A. Linthicum, of Helena, Ark.; Charles Denison, of Denver, Col.; W. C. Wile, of Sandy Hook, Conn.; L. P. Bush, of Wilmington, Del.; A. Y. P. Garnett, of Washington; R. D. Murray, of Florida; R. Battey, of Rome, Ga.; E. P. Cook, of Mendota, Ill.; F. M. Beard, of Vincennes, Ind.; W. Watson, of Dubuque, Iowa.; D. W. Stormont, of Topeka, Kansas; W. H. Wathen, of Louisville; J. W. Dupree, of Baton Rouge, La.; S. C. Gordon, of Portland, Me.; A. H. Wilson, of South Boston, Mass.; A. R. Smart, of Hudson, Mich.; George F. French, of Minneapolis; J. M. Taylor, of Corinth, Miss.; N. F. Essig, of Plattsburg, Mo.; R. C. Moore, of Omaha, Neb.; J. W. Parsons, of Portsmouth, N. H.; William Pierson, of Orange, N. J.; Ellsworth Eliot, of New York; *Thomas F. Wood*, of Wilmington, N. C.; X. C. Scott, of Cleveland; W. E. Anthony, of Providence; R. A. Kinloch, of Charleston; F. L. Sim, of Memphis; William McLaughlin, of Austin, Texas; W. C. Dabney, of Char-

lottesville, Va.; E. T. Upham, of West Randolph, Vt.; G. Baird, of Wheeling; *N. Senn*, of Milwaukee; Robert Murray, U. S. A.; J. B. Hamilton, U. S. Marine-Hospital Service; F. M. Gunnell, U. S. N.

SECTION 1.—MEDICAL EDUCATION, LEGISLATION, AND REGISTRATION.

(Abolished at the New York Meeting.)

PRESIDENT.—*Dr. S. E. Chaillé*, of New Orleans.

VICE-PRESIDENTS.—Drs. George Cupples, of Texas; R. J. Dunglison, of Philadelphia.

SECRETARY.—Dr. E. Dunbar, of Boston.

COUNCIL.—Drs. H. D. Didama, of Syracuse; Henry Gibbons, of San Francisco; D. C. Gilman, of Baltimore; Jas. F. Harrison, of the University of Virginia; Charles A. Lindsley, of New Haven; *William Pepper*, of Philadelphia; J. F. Prioleau, of Charleston; *L. McLane Tiffany*, of Baltimore; C. L. Allen, of Rutland, Vt.; J. A. Dibrell, of Little Rock; H. O. Hitchcock, of Kalamazoo; J. W. Bailey, of Gainesville, Ga.; H. King Wylie, of Sanford, Fla.

SECTION 2.—ANATOMY.

PRESIDENT.—Drs. *Joseph Leidy*, of Philadelphia; W. H. Pancoast, of Philadelphia

VICE PRESIDENTS.—Drs. C. W. Kelly, of Louisville; Samuel Logan, of New Orleans.

SECRETARIES.—*Drs. William W. Keen*, of Philadelphia; *George E. De Schweinitz*, of Philadelphia.

COUNCIL.—Drs. *Harrison Allen*, of Philadelphia; *Frank Baker*, of Washington; *Thomas Dwight*, of Boston; *Francis L. Parker*, of Charleston; *Charles T. Parkes*, of Chicago; Thomas T. Sabine, of New York; *Nicholas Senn*, of Milwaukee; Francis J. Shepherd, of Montreal; *Robert W. Shufeldt*, U. S. A.; George Halley, of Kansas City; A. Hewson, of Philadelphia; M. S. Craft, of Jackson, Miss.

SECTION 3.—PHYSIOLOGY.

PRESIDENT.—Dr. John C. Dalton, of New York.

VICE-PRESIDENTS.—Drs. *H. P. Bowditch*, of Boston; *J. F. Hibberd*, of Richmond, Ind.; H. N. Martin, of Baltimore; *Middleton Michel*, of Charleston.

SECRETARY.—Dr. John G. Curtis, of New York.

COUNCIL.—Drs. G. Baumgarten, of St. Louis; *Henry G. Beyer*, U. S. N.; Austin Flint, Jr., of New York; *William Lee*, of Washington; John J. Mason, of Newport; *Henry Sewall*, of Ann Arbor; W. F. Hyer, of Holly Springs, Miss.; *J. H. Wythe*, of San Francisco; Thos. S. Latimer, of Baltimore; A. F. Whelan, of Hillsdale, Mich.; S. Putnam, of Montpelier, Vt.; C. H. A. Kleinschmidt, of Washington; A. D. Brubaker, of Philadelphia.

SECTION 4.—PATHOLOGY.

PRESIDENT.—Drs. *Francis Delafield*, of New York; E. O. Shakespeare, of Philadelphia.

VICE-PRESIDENT.—*Dr. William Pepper*, of Philadelphia.

SECRETARIES.—Drs. William H. Welch, of Baltimore; H. M. Biggs, of New York.

COUNCIL.—Drs. *Christian Fenger*, of Chicago; *Reginald H. Fitz*, of Boston; Edward G. Janeway, of New York; James B. Johnson, of St. Louis; *George M. Sternberg*, U. S. A.; *William F. Whitney*, of Boston; C. H. Hunter, of Minneapolis; H. D. Schmidt, of New Orleans; *Morris Longstreth*, of Philadelphia.

SECTION 5.—MEDICINE.

PRESIDENT.—Drs. *J. M. DaCosta*, of Philadelphia; A. B. Arnold, of Baltimore.

VICE-PRESIDENTS.—Drs. *James B. McCaw*, of Richmond; *Richard McSherry*, of Baltimore; A. B. Palmer, of Ann Arbor; Thomas F. Rochester, of Buffalo; A. Clark, of New York; *S. Weir Mitchell*, of Philadelphia; P. G. Robinson, of St. Louis.

SECRETARIES.—Drs. *Wm. Osler*, of Philadelphia; R. Harvey Reed, of Mansfield, Ohio; Walter Hay, of Chicago.

COUNCIL.—Drs. *S. C. Chew*, of Baltimore; *W. H. Geddings*, of Aiken, S. C.; *W. W. Johnston*, of Washington; George A. Ketchum, of Mobile; *Francis Minot*, of Boston; *Beverley Robinson*, of New York; *James T. Whittaker*, of Cincinnati; Jeff. Williamson, of Ottumwa, Iowa; T. B. Lester, of Kansas City; E. Grissom, of Raleigh; W. H. Phillips, of Canton, Ohio; J. P. Logan, of Atlanta; E. D. Ferguson, of Troy, N. Y.; J. Burnett, of Cleveland; S. S. Clark, of St. Albans, Vt.; J. Draper, of Brattleboro'; *Charles F. Folsom*, of Boston; John P. Gray, of Utica; J. S. Jewell, of Chicago; *Roberts Bartholow*, of Philadelphia; *Francis T. Miles*, of Baltimore; *Samuel G. Webber*, of Boston; Peter Bryce, of Tuscaloosa; W. W. Cleaver, of Lebanon, Ky.

SECTION 6.—SURGERY.

PRESIDENT.—Drs. *David W. Yandell*, of Louisville; William T. Briggs, of Nashville.

VICE-PRESIDENTS.—Drs. *D. Hayes Agnew*, of Philadelphia; *Samuel W. Gross*, of Philadelphia; W. H. Hingston, of Montreal; *R. A. Kinloch*, of Charleston; E. M. Moore, of Rochester; Moses Gunn, of Chicago.

SECRETARIES.—Drs. *John Collins Warren*, of Boston; Dudley P. Allen, of Cleveland.

COUNCIL.—Drs. *John Ashhurst, Jr.*, of Philadelphia; *David W. Cheever*, of Boston; *P. S. Conner*, of Cincinnati; George E. Fenwick, of Montreal; *F. H. Gerrish*, of Portland, Me.; J. C. Hutchison, of Brooklyn; *Christopher Johnston*, of Baltimore; Thomas M. Markoe, of New York; *Alan P. Smith*, of Baltimore; J. Ford Thompson, of Washington; Theodore R. Varick, of Jersey City; O. Coskery, of Baltimore; Jas. McCann, of Pittsburg; H. H. Mudd, of St. Louis; W. F. Westmoreland, of Atlanta; J. P. Wall, of Tampa, Fla.; Leroy M. Bingham, of Burlington, Vt.; T. A. Dunsmoor, of Minneapolis; J. T. Carpenter, of Pottsville; W. S. Janney, of Philadelphia; J. E. Garrettson, of Philadelphia; I. N. Quimby, of Jersey City; H. H. Smith, of Philadelphia; J. R. Weist, of Richmond, Ind.; S. D. Mercer, of Omaha; T. A. McGraw, of Detroit; W. F. Andrews, of Mitchell, Dakota; W. H. Austin, U. S. M. H. S.; C. A. Wheaton, of St. Paul; Thomas R. Russell, of Oshkosh, Wis.; J. H. Ransom, of Burlington, Iowa.

SECTION 7.—OBSTETRICS.

PRESIDENT.—Dr. De Laskie Miller, of Chicago.

SECTION 8.—GYNECOLOGY.

PRESIDENT.—Dr. Robert Battey, of Rome, Ga.

VICE-PRESIDENTS. — Drs. *William T. Howard*, of

Baltimore; R. B. Maury, of Memphis, *J. C. Reeve*, of Dayton; *Albert H. Smith*, of Philadelphia; T. Opie, of Baltimore; *T. A. Reamy*, of Cincinnati; W. H. Byford, of Chicago; *H. P. C. Wilson*, of Baltimore; T. Gaillard Thomas, of New York.

SECRETARIES.—*Drs. James R. Chadwick*, of Boston; *George J. Engelmann*, of St. Louis.

COUNCIL.—Drs. *Robert P. Harris*, of Philadelphia; *A. F. A. King*, of Washington; William T. Lusk, of New York; *Theophilus Parvin*, of Philadelphia; John Scott, of San Francisco; Donald Maclean, of Council Bluffs; H. O. Marcy, of Boston: D. W. C. Wey, of Holly, Mich.; *E. S. Dunster*, of Ann Arbor; Luke Robinson, of San Francisco; B. E. Hadra, of San Antonio, Texas; R. S. Sutton, of Pittsburg; R. Glisan, of Portland, Oregon; Wm. Varian, of Titusville; C. V. Mottram, of Lawrence, Kansas; E. P. Sale, of Aberdeen, Miss.; T. B. Harvey, of Indianapolis; E. Warner, of Worcester, Mass.; Lorenzo Fay, of Lowell, Mass.; *W. H. Baker*, of Boston; Wm. Gardner, of Montreal; *William Goodell*, of Philadelphia; *A. Reeves Jackson*, of Chicago; *J. Taber Johnson*, of Washington; *E. Van de Warker*, of Syracuse.

SECTION 9.—OPHTHALMOLOGY.

PRESIDENT.—Drs. *E. Williams*, of Cincinnati; A. W. Calhoun, of Atlanta, Ga.

VICE-PRESIDENTS.—Drs. *H. D. Noyes*, of New York; *William Thomson*, of Philadelphia; E. L. Holmes, of Chicago.

SECRETARY.—*Dr. Swan M. Burnett*, of Washington.

COUNCIL.—Drs. C. S. Bull, of New York; *Hasket Derby*, of Boston; E. G. Loring, of New York; *William F. Norris*, of Philadelphia; *W. W. Seely*, of Cincinnati; *Samuel Theobald*, of Baltimore; *O. F. Wadsworth*, of Boston; *Henry W. Williams*, of Boston; Peter D. Keyser, of Philadelphia; David Hunt, of Boston; *J. J. Chisolm*, of Baltimore; John Green, of St. Louis; B. Joy Jeffries, of Boston; *B. E. Freyer*, of Kansas City; —— Minney, of Topeka; B. Baldwin, of Montgomery, Ala.; E. Smith, of Detroit; J. L. Thompson, of Indianapolis; A. G. Sinclair, of Memphis; W. H. Sanders, of Mobile.

SECTION 10.—OTOLOGY (AND LARYNGOLOGY).

PRESIDENT.—Drs. *Clarence J. Blake*, of Boston; S. J. Jones, of Chicago.

VICE-PRESIDENTS.—Drs. *H. N. Spencer*, of St. Louis; A. M. Wilder, of San Francisco; D. W. Reynolds, of Louisville.

SECRETARY.—*Dr. S. O. Richey*, of Washington.

COUNCIL.—Drs. *J. Orne Greene*, of Boston; *George Strawbridge*, of Philadelphia; *C. H. Burnett*, of Philadelphia; C. S. Turnbull, of Philadelphia; C. J. Lundy, of Detroit; E. H. Hazen, of Davenport, Iowa; J. C. Lippincott, of Pittsburg; J. H. White, of Richmond.

SECTION 11.—DERMATOLOGY AND SYPHILIS.

PRESIDENT.—Drs. *W. A. Hardaway*, of St. Louis; A. R. Robinson, of New York.

VICE-PRESIDENTS.—Drs. *L. A. Duhring*, of Philadelphia; *James Nevins Hyde*, of Chicago; *James C. White*, of Boston; J. M. Keller, of Hot Springs, Ark.

SECRETARIES.—Drs. F. E. Daniel, of Fort Worth; W. T. Corlett, of Cleveland.

COUNCIL.—Drs. *I. E. Atkinson*, of Baltimore; *Edward Wigglesworth*, of Boston; *Henry C. Yarrow*, of Washington; H. R. Carter, U. S. M. H. S.; J. A. Octerlony, of Louisville; J. H. McAchran, of Laramie City, Wyoming Territory; H. O. Walker, of Detroit; W. F. Glenn, of Nashville; *Legrand N. Denslow*, of St. Paul.

SECTION 12.—LARYNGOLOGY.

(Combined with Section on Otology.)

PRESIDENT.—*Dr. J. N. Mackenzie*, of Baltimore.

VICE-PRESIDENTS.—Drs. *Frederick I. Knight*, of Boston; M. F. Coomes, of Louisville.

SECRETARIES.—Drs. *D. Bryson Delavan*, of New York; E. Fletcher Ingalls, of Chicago.

COUNCIL.—Drs. W. H. Daly, of Pittsburg; George W. Major, of Montreal; *E. Carroll Morgan*, of Washington; William Porter, of St. Louis; E. L. Shurley, of Detroit; *R. P. Lincoln*, of New York; C. E. Sajous, of Philadelphia; N. Goldthwaite, of New York.

SECTION 13.—PUBLIC AND INTERNATIONAL HYGIENE.

PRESIDENT.—Drs. *Hosmer A. Johnson*, of Chicago; Dr. Joseph Jones, of New Orleans.

VICE-PRESIDENTS.—Drs. *A. L. Carroll*, of New York; J. L. Cabell, of the University of Virginia; J. B. Lindsley, of Nashville; J. E. Reeve, of Wheeling; J. N. McCormick, of Bowling Green, Ky.

SECRETARIES.—Drs. Walter Wyman, U. S. M. H. S.; G. H. Rohé, of Baltimore.

COUNCIL.—Drs. H. B. Baker, of Lansing; *Granville P. Conn*, of Concord, N. H.; *William H. Ford*, of Philadelphia; D. W. Hand, of St. Paul; *J. H. Kidder*, of Washington; J. H. Rauch, of Springfield, Ill.; J. H. Raymond, of Brooklyn; *Jos. R. Smith*, U. S. A.; Stephen Smith, of New York; *H. P. Wolcott*, of Cambridge, Mass.; J. B. Thornton, of Memphis; H. S. Orme, of Los Angeles; R. M. Swearingen, of Austin; H. Leffmann, of Philadelphia; C. M. Hewit, of Red Wing; E. L. B. Godfrey, of Camden, N. J.. W. L. Schenck, of Osage City, Kan.; Benjamin Lee, of Philadelphia; Dudley P. Hart, of Ark.; Joseph Holt, of New Orleans; W. S. Robertson, of Muscatine, Iowa; A. L. Gihon, U. S. N.; E. S. Elder, of Indianapolis; O. C. De Wolf, of Chicago; H. F. Lyster, of Detroit.

SECTION 14.—COLLECTIVE INVESTIGATION, NOMENCLATURE, VITAL STATISTICS, AND CLIMATOLOGY.

PRESIDENT.—Dr. H. O. Marcy, of Boston.

VICE-PRESIDENTS.—Drs. Jerome Cochran of Mobile; *Edwin M. Snow*, of Providence.

SECRETARY.—Dr. James F. Ford, of Chicago.

COUNCIL.—Drs. *Nathan Allen*, of Lowell; *R. A. Cleemann*, of Philadelphia; J. H. Hollister, of Chicago; James T. Reeve, of Appleton, Wis.; *James Tyson*, of Philadelphia; A. C. Hamlin, of Bangor; T. J. Allen, of Shreveport; A. T. Saball, of Jacksonville, Fla.; T. S. Hopkins, of Thomasville, Ga.; O. W. White, of Detroit; J. W. Parsons, of Portsmouth, N. H.; P. C. Remendino, of Santiago, Cal.; T. T. Minor, of Seatle, Washington Ter.; Chas. Denison, of Denver; H. C. Ghent, of Belton, Texas; *E. P. Hurd*, of Newburyport; E. W. Morley, of Cleveland; W. P. Hart, of Washington, Ark.; R. D. Webb, of Livingston, Ala.

VICE-PRESIDENTS.—Drs. F. H. Hamilton, of New York; *Hunter McGuire*, of Richmond; *S. P. Moore*, of Richmond; Wm. E. Taylor, U. S. A.; P. O. Hooper, of Little Rock; E. Andrews, of Chicago; E. H. Gregory, of St. Louis; Donald McLean of Ann Arbor.

SECRETARIES.—Drs. B. F. Pope, U. S. A.; J. McF. Gaston, of Atlanta.

COUNCIL.—Drs. *D. Bloodgood*, U. S. A.; R. B. Bontecou, of Troy, N. Y.; *J. H. Brinton*, of Philadelphia, E. J. Marsh, of Paterson, N. J.; *C. H. Mastin*, of Mobile; George Peck, U. S. N.; W. F. Peck, of Davenport, Iowa; Charles Smart, U. S. A.; *J. Rufus Tryon*, U. S. N.; *A. A. Woodhull*, U. S. A.; J. W. Hamilton, of Columbus, O.; J. H. Murphy, of St. Paul; W. C. B. Fifield, of Boston; E. Goodman, of Philadelphia; W. S. Tremaine, U. S. A.; J. H. Peabody, of Omaha; S. T. Armstrong, U. S. M. H. S.

SECTION 16.—PRACTICAL AND EXPERIMENTAL THERAPEUTICS.

PRESIDENT.—Drs. *Horatio C. Wood*, of Philadelphia; F. H. Tirrell, of San Francisco.

VICE-PRESIDENTS.—Drs. *Robert T. Edes*, of Boston; *F. Peyre Porcher*, of Charleston; E. R. Squibb, of Brooklyn.

SECRETARIES.—*Drs. Edward T. Reichert*, of Philadelphia; *Robert Meade Smith*, of Philadelphia.

COUNCIL.—Drs. *Robert Amory*, of Boston; *Henry M. Lyman*, of Chicago; *Samuel Nickels*, of Cincinnati; Isaac Ott, of Easton; *D. Webster Prentiss*, of Washington; Charles Rice, of New York; *Charles H. White*, U. S. N.; *Thomas F. Wood*, of Wilmington, N. C.; G. Griswold, of New York; F. Stewart, of Cincinnati; J. M. Flint, U. S. N.; E. P. Fraser, of Portland, Oregon; W. G. Breck, of Springfield, Mass.; F. Woodbury, of Philadelphia; J. B. Van Velsas, of Yankton, Dakota; A. B. Tadlock, of Knoxville, Tenn.; J. F. Payne, of Galveston; T. Weed, of Cleveland; D. W. C. Wade. of Holly, Mich.; R. C. Moore, of Omaha; *G. M. Garland*, of Boston; —— Buddick, of Omaha; Wm. Comton, of Lancaster, Pa.

SECTION 17.—DISEASES OF CHILDREN.

PRESIDENT.—Dr. J. Lewis Smith, of New York.

VICE-PRESIDENTS.—Drs. *Samuel C. Busey*, of Washington; De Laskie Miller, of Chicago.

SECRETARY.—Dr. E. T. Williams, of Boston.

COUNCIL.—Drs. *F. Forcheimer*, of Cincinnati; *John M. Keating*, of Philadelphia; *Wm. Lee*, of Baltimore; John H. Pope, of Marshall, Texas; W. B. Atkinson, of Philadelphia; E. Walker, of Evansville, Ind.; W. A. Conklin, of Dayton, Ohio: W. F. Holt, of Macon, Ga.; G. K. Johnson, of Grand Rapids, Mich.; C. A. Leale, of New York; S. H. Charlton, of Seymour, Ind.; W. H. Doughty, of Augusta, Ga.; B. H. Riggs, of Selma, Ala.; H. H. Middlekamp, of Warrenton, Mo.; J. A. Hodge, of Henderson, Ky.; G. W. Moody, of Huron, Dakota; A. A. Horner, of Helena, Ark.

The vacancies in the different Sections caused by the numerous resignations were filled and "lists of Vice Presidents, Secretaries, and Councilmen for each Section were named by the Committee of Arrangements, but as it was not practicable to ascertain at once who would accept the places assigned them, or who of those who had been announced in the medical press as declining to accept positions before the present rules and organization had been adopted, as given heretofore, might wish to withdraw such declination, the final adjustment of these offices was referred to the Executive Committee of the Congress, and all correspondence in relation thereto was transferred to the Secretary-General of the Congress."

The rule concerning membership was altered so as to read "The Congress shall consist of members of the regular profession of medicine, and of such other scientific men as the Executive Committee of the Congress may see fit to admit, who shall have inscribed their names on the register, and shall have taken out their tickets of admission." An amendment was offered that all members of the Congress shall be eligible to election of office, but it was summarily rejected; the overwhelming sentiment of the Committee being that none but members of the American Medical Association, or of societies in affiliation with it, shall hold office in the proposed Congress.

PUBLIC OPINION ON THE CONGRESS OUTLOOK.—The Committee, we have every reason to believe, made no concessions which can be accepted as such. They filled the one hundred and twenty odd vacancies with gentlemen sufficiently unknown to fame to have escaped nomination by them before, and presumably sufficiently poor in spirit to accept belated honors.—*Medical Record*, Sept. 12, 1885.

It would be idle to attempt concealment of the fact that not only is the success of the proposed meeting of the International Medical Congress at Washington imperilled by existing dissensions in the profession of America, but that it is a serious question whether the gathering can be permitted to be held there at all. We are alive to the possibility that the curious arrangements entered into by the clique of the American Medical Association may be fully carried out; but at the same time we are perfectly certain that a congress convened under such circumstances will not be international in any sense of the word, but will develop into nothing more imposin than a magnified mutual admiration society. There is no longer any doubt that all the leading members of the profession in America will at such a gathering be conspicuous by their absence, or that European practitioners will fail to find any recompense for this fact in receiving attentions from gentlemen whose names they are unable to associate with the extension or perfection of scientific knowledge or the advancement of the art of medicine.—*Medical Press and Circular.*

As the matter now stands, any member of the regular medical profession in this country is entitled to a seat on the floor of the Congress, but none who have declared in favor of the New Code heresy are permitted to sit in a position the least elevated. The New Code men are now given the privilege of being full privates, but they are debarred from all possibility of occupying any position above the ranks. Whether the heretics will thank-

Digitized by Google

fully accept the crumbs thus graciously thrown out to them remains to be seen. It is barely possible that they will not. Their admission to the Congress, they may possibly argue, is a concession that they are members of the medical profession of this country. This being the case, they may, in the obstinacy of their hearts, hold that no discrimination should be made against them in a Congress of the medical men of all countries, which is about to be held in this country, in pursuance of an invitation which was worded expressly to carry the idea that it came, not from any medical association, or other body of medical men, but from the medical profession of America, regardless of codes of ethics or aught else not strictly of a scientific nature. Had the invitation been issued by the American Medical Association on its own behalf, and not expressly on behalf of the entire profession, and as such been accepted by the last Congress, physicians not members of the Association would, doubtless, have felt complimented on being permitted to sit on the floor of the coming Congress. As matters actually stand, however, they may regard it as a piece of unwarrantable assumption when any medical society to which they may not belong seeks to lord it over them. They may be presumptuous enough to believe that they have quite as much right to share the honors of the Congress as has the Association which usurps the right to dole them out.

The Committee did a good work in rescinding the rule which closed the doors of the Congress against such members of the profession as hold independent views regarding the propriety of meeting in consultation those holding different views touching the action of drugs, and we cannot but regret that it did not also distribute among these gentlemen some of the honors of the Congress. Having acknowledged and attempted to correct the error of the Association in instructing it to exclude these gentlemen from the Congress, it should have gone a little further and removed all the obstacles to the complete success of the coming meeting.—*The Medical Age* (Detroit), September 10, 1885.

LUZERNE COUNTY (PA.) MEDICAL SOCIETY AND THE INTERNATIONAL MEDICAL CONGRESS.—At the stated meeting of the Luzerne County Medical Society held at Wilkes-Barre on Wednesday, September 9th, the following resolution, offered by Drs. Mayer and Guthrie, was discussed and then carried, but one vote being recorded in the negative:

Whereas, The International Medical Congress is a scientific body taking no cognizance of medical ethics or politics, therefore be it

Resolved, That it is the sense of the Luzerne County Medical Society that the officers and members of the Medical Congress should be the most eminent representatives of the entire regular profession of our country without regard to their views as to extraneous subjects.

Resolved, That the action of our brethren of Philadelphia, and of other cities, in declining to hold office in connection with the said Congress as now proposed to be organized, and in protesting against the method of its organization, is hereby heartily approved.

In seconding the motion for the acceptance of the preamble and resolutions offered by Dr. Guthrie, Dr. Mayer said:

I desire to state that I had intended presenting to you to-day other resolutions of similar tenor, but upon learning of Dr. Guthrie's purpose, will content myself with endeavoring to further the passage of these, which I so so highly approve.

This whole matter referred to in the resolutions, when compressed into a nutshell, would seem to be as follows: That the committee of our National Association originally appointed to secure a proper representation of delegates and committees for the coming International Congress, made selections which gave satisfaction to the best professional judgment of our country; that then certain aspiring and neglected members of the Association, conspired at the last moment to exclude from the appointed list a large number of men favorably known abroad and distinguished at home for their zeal and success in scientific labors, upon the plea that these gentlemen differed from the majority of the Association about ethical matters, well the subjects of legitimate controversy. They succeeded in their plot and in the enforced substitution for many honored names, of others comparatively obscure. This action has caused a profound sensation in medical circles, and has aroused the best sentiment of the country in opposition to this usurpation. A large number of the ablest, the purest, and also the most conservative members of our profession, including near at hand such lights as D. Hayes Agnew, Bartholow, Stillé, Leidy, Mitchell, and Pepper, and at a distance other prominent men in New York, Boston, Baltimore, the South, and the West, have combined in a protest against this action of the Modified Committee and have declined to fill the positions assigned to them unless the original status of things be restored. In the meantime some of the members of this Committee are inundating the land with proclamation and manifesto, and are endeavoring by public circular and private solicitation to whip and spur county societies and individual members into adherence to their views.

I trust that our Society will now speak "with no uncertain sound" and place its stamp of reprobation upon this despotic attempt of a few to coerce the many, and by a unanimous vote confirm the manly protest made by our distinguished brethren in behalf of all that is broad, high-toned, liberal, and free in American medicine. Its name has been soiled in the dust of corrupt medical politics. Let us do our little to help cleanse it.

REWARD OFFERED.—*The Kansas City Medical Record* offers to pay a liberal reward for a germicide that will destroy the microbes that were instrumental in ruining the International Medical Congress and weakening the vitality of the American Medical Association by their onslaught at New Orleans.

THE AMERICAN GYNECOLOGICAL SOCIETY will hold its Tenth Annual Meeting at the Columbian University, in Washington, on Tuesday, Wednesday, and Thursday, September 22, 23, and 24, 1885.

Among the papers announced to be read are the following: The Natural Hygiene of Child-bearing Life, by Dr. S. C. Busey, of Washington; Remarks on the Use of Tarnier's Forceps, by Dr. Ellwood Wilson, of Philadelphia; Facial Paralysis in the Infant from the Use of the Obstetric Forceps, by Dr. T. Parvin, of Philadelphia; The Genu-pectoral Posture in the Prolonged Nausea and Vomiting of Pregnancy, with Cases, by Dr. H. F. Campbell, of Augusta, Ga.; Two Rare Cases of Abdominal Surgery (The President's Ad-

Digitized by Google

dress), by Dr. W. T. Howard, of Baltimore; The Care of the Perineum during Labor, by Dr. T. A. Reamy, of Cincinnati; Report of a Case of Cæsarean Operation, by Dr. E. W. Jenks, of Detroit; Puerperal Diphtheria, by Dr. H. J. Garrigues, of New York; A Modification of Emmet's Cervix Operation in Certain Cases, with a Case, by Dr. R. S. Sutton, of Pittsburg; Inflammation of the Parotid Glands after Ovariotomy, by Dr. William Goodell, of Philadelphia; A Study of an Unusual Type of Puerperal Fever, by Dr. Fordyce Barker, of New York; Peristalsis of the Genital Tract, by Dr. J. R. Chadwick, of Boston; Four Cases of Oöphorectomy, with Remarks, by Dr. Joseph Taber Johnson, of Washington. Members of the profession are cordially invited to attend the meeting.

SMALLPOX CASES IN MONTREAL.—There were 48 deaths from smallpox in Montreal last Sunday, and in the week ending on that day there were 128 deaths. Of these 118 were French-Canadian Catholics, five other Catholics, five Protestants, and 111 were under ten years of age.

In answer to a question last Monday the chairman of the Health Committee said that there were probably 800 cases in the city. A number of cases are reported in the suburbs adjoining Montreal. In a building called Noah's Ark, where twenty-four families live, five deaths occurred on Saturday, and one dead patient and seventeen live ones were removed from there on Monday last.

A meeting of the Citizens' Committee was held on Monday afternoon, when the inaction of the Civic Board of Health was severely criticised. A petition was then read which asked that the City Council grant to the Citizens' Committee what should be known as the Emergency Health Committee, and incorporate them with the Civic Health Committee. If this authority was granted they would within six hours begin complete isolation of all known patients, by the erection and completion within six days of additional temporary hospital accommodation. House to house inspection will be made to reveal unreported cases and to see that all persons are vaccinated. At the meeting of the Council it was decided to increase the Board of Health by five members and to add nine members of the Citizens' Committee to act in concert with them.

At a meeting of the Provincial Board of Health a regulation was passed granting to all health officials and medical men full power to enter all houses where smallpox might be supposed to exist, as well as factories, mills, and other establishments, and to order any measures which they may deem advisable to prevent the spreading of the epidemic. The Civic Hospital was taken charge of on Monday by the Gray Nuns.

The Finance Committee has granted $50,000 to stamp out the epidemic, and the Chairman has been authorized to give whatever sum the Health Board asks for.

THE NEW YORK STATE BOARD OF HEALTH is making arrangements to furnish vaccine virus for the purpose of vaccinating people all along the Canadian border of the State.

A PRIZE FOR THE BEST INSTRUMENT FOR THE IMPROVEMENT OF HEARING.—Baron Léon de Lenval, of Nice, has offered by occasion of the Third International Congress for Otology, a prize of 3000 francs for the best instrument (easily carried), constructed according to the principle of the microphone for improvement of hearing in cases of partial deafness.

Instruments of this description, intended for competition, are to be sent before the 31st of December, 1887, to one of the undersigned, members of the jury, appointed at the instance of Baron Léon de Lenval, by the Third International Congress for Otology. Such instruments only are admitted to compete as are completely worked out; at the examination the perfection of the mechanical construction, the right application of the laws of physics, and, above all, the power of improving the hearing will be taken into consideration.

The verdict of the jury and the awarding of the prize will take place at the Fourth International Congress for Otology, to be held at Brussels, in September, 1888. Should none of the instruments presented be found worthy of obtaining the prize, the jury reserve to themselves the right of keeping the competition open until the meeting of the next International Congress for Otology.

The members of the jury are Prof. Hagenbach Bischoff, Ph. D., M.D., Chairman of the Jury, Basle (Missionsstr. 20); Benni, M.D., Warsaw (16 Bracka); Prof. Burckhardt-Merian, M.D., Basle (42 Albanvorstadt); Gellé, M.D., Paris (49 Rue Boulard); Prof. Adam Politzer, M.D., Vienna (I Gonzagagasse 19).

OBITUARY RECORD.—DR. EUGENIUS A. HILDRETH, one of the most prominent physicians and citizens of Wheeling, Va., died, after a short illness, August 31, ult., after an active professional life of nearly forty years. He was a careful observer of atmospheric phenomena, and his writings on this and kindred subjects are particularly interesting and useful.

A cablegram dated London, September 12, announces the death of WILLIAM AUGUSTUS GUY, M.B., F.R.S., the eminent physician and author of a number of medical works. Dr. Guy was born at Chichester, England, in 1810. He was educated at Guy's Hospital and Pembroke College, Cambridge. In 1838 he was appointed Professor of Forensic Medicine in King's College, London. In 1846 he became Dean of the Medical Department, which position he held until 1858. In 1869 he was made Professor of Hygiene. Dr. Guy wrote many essays on subjects connected with public health and toxicology, and he was the author of a well-known textbook on *The Principles of Forensic Medicine*.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICES SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 8 TO SEPTEMBER 14, 1885.

MCKEE, J. C., *Major and Surgeon.*—Sick leave still further extended three months, on Surgeon's certificate of disability.—*S. O. 204, A. G. O.*, September 7, 1885.

PATZKI, J. H., *Captain and Assistant Surgeon.*—Assigned to duty as Post Surgeon at Jackson Barracks, New Orleans, La.—*S. O. 192, Department of the East*, September 9, 1885.

POLHEMUS, A S., *First Lieutenant and Assistant Surgeon.*—When relieved at Fort McDermit, Nevada, assigned to temporary duty at Presidio of San Francisco, Cal.—*S. O. 87, c. s., Department of California.*

KENDALL, WM. P., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Presidio of San Francisco, Cal., and assigned to duty as Post Surgeon at Fort McDermit, Nevada, relieving Assistant Surgeon Polhemus.—*S. O. 57, Department of California*, August 31. 1885.

ORIGINAL LECTURES.

THE GROWTH OF A PROFESSION.

An Address, delivered at the Eighteenth Annual Meeting of the Canada Medical Association, held at Chatham, Ontario, September 2 and 3, 1885.

BY WILLIAM OSLER, M.D.,
PRESIDENT OF THE ASSOCIATION, PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

GENTLEMEN: When I removed last year to another part of the great field in which, without distinction of race or country, we are all laborers, it seemed good to you, fellow-workers, in the kindness of your hearts, to nominate me President of the Association. If in the tumult of thoughts which come tumbling unbidden into a man's mind, the idea of such an honor ever came, truly it was as a speck in the horizon of my ambition towards which, as years rolled on, I might travel; but it has been ordered otherwise, and as exceptional circumstances have placed me in an exceptional position, I can but crave your indulgence in the exercise of an office for which I feel that I lack certain important qualifications.

Let me, in the first place, give expression to the general regret that the Association has not been able to carry out its programme and meet in Winnipeg as had been arranged, but with Mars in the ascendant, and Big Bear and Poundmaker on the warpath, our brethren of the prairie city thought it would be better—perhaps safer—to postpone the meeting in the Northwest unto a more convenient season, when grim-visaged war shall have smoothed its wrinkled front. But, again, let me express the satisfaction we feel at being able to meet here in Chatham among men we know so well, who have been so faithful to the Association, and in a section of the country in which the profession possesses so many able and industrious members.

In seeking for a theme upon which to address you, I felt that if we met in Winnipeg, some subject connected with growth and development would alone be in keeping with the remarkable progress which the Northwest and its capital have made during the past decade. I thought that by tracing the lines along which the profession in a new country should advance, the meeting might perhaps help the movement and give a stimulus to thought and action, which is often one of the best effects of gatherings of this kind. When circumstances necessitated a change in the place of meeting, it seemed as if my subject, upon which I had spent some thought, should also be changed; but, on reflection, it was evident that the conditions in the older provinces were only an advanced stage of those existing in Winnepeg and Manitoba—progress should be our watchword here as there, growth and development the essential features of our professional life, and upon these topics I could as well address you in Ontario as in the Northwest. I want then to tell you, in as few words as possible, just how far on we have got and what have been the methods of our progress. In some parts of the Dominion we may study the profession in its simplest form; in the Northwest Territories, for example, it has not advanced beyond the amœba stage. The doctors there are so many unicellular creatures—masses of undifferentiated professional protoplasm, without organization or special functional activities. They cannot even exercise the rhizopodal mode of multiplication, but increase by the low inorganic method of accretion. In the older Provinces, on the other hand, the professional units have combined for the general good into a sort of polypidom—the organized profession—a great advance on the amœba stage; there are special organs of reproduction known as the medical schools, and there are signs of a nervous system—medical societies.

The three aspects then in the growth and development of the profession to which I wish to direct your attention, are (1) the organized profession; (2) the medical school; and (3) the medical society:

1. The organized profession. In a well-arranged community a citizen should feel that he can at any time command the services of a man who has received a fair training in the science and art of medicine, into whose hands he may commit with safety the lives of those near and dear to him. For the State to regulate and determine the individuals to whom the citizen may apply, is not by most persons thought unreasonable. There are those, however, who would have no restrictions, but allow the utmost freedom and permit assumption and assurance to have full sway, and give to any man without special education the right to practise medicine. This has never been the case in Canada. The men who came here in the early days to practise medicine were chiefly English and Scotch licentiates, who brought with them the traditions and customs of the profession in Great Britain. Very many of them were army surgeons, accustomed by long training to system and discipline. Without medical schools, the only recourse for a young man wishing to enter the profession was either to cross the ocean or to serve an apprenticeship with and receive instruction from a practitioner. Boards for the inspection of diplomas of men coming from outside the country and for the examination of the young men who had passed the necessary time with local preceptors, were organized in the old Province of Quebec in 1788, and in Upper Canada in 1815—dates ever to be memorable in the history of medicine in this country.

It is a common experience that men do not always appreciate their blessings and advantages. Those who are the best off are the least sensible of it. I have often thought this of the profession in Canada in relation to the Medical Boards, when I have heard murmurs of discontent. As they constitute a special feature in the Canadian medical system, you will allow me to refer to their origin and functions at some length. Primarily, the Medical Board is simply a Bureau of Registration

Digitized by Google

appointed by the State, as, in fact, the British Medical Council is to-day; but here, at an early period, before the establishment of schools and universities, it was an examining body as well, and granted permits to practise. As universities sprang up, the latter part of the duties of the Medical Board was in part abrogated, and the functions more or less limited to the registration of degrees. An exceedingly important change was effected when the boards became elective bodies, truly representative of the profession. In Ontario, this was brought about by the Act of 1866, and in Quebec, by the Act of 1847. In this province the mode of selection of members is truly democratic, the profession in each electorial district selecting their candidate. In the province of Quebec a more cumbrous and less distinctly popular mode is followed, whereby each constituent of a district votes not only for his own, but for the candidates in all other districts. As proxies are allowed, the entire election may be in the hands of any clique collecting the largest number, but this method is doomed, and the more popular one will shortly be introduced.

The struggle has all along been between the universities and the profession, as represented by the Medical Boards. The former have always maintained the right of their alumni to license without further examination—a privilege still granted in the Province of Quebec. But the universities chartered by the crown in past days did more, they opposed bitterly the incorporation of independent medical schools, as witness the hostility to the Montreal School of Medicine by the McGill University, and to the Toronto School of Medicine by the University of Toronto. Much of this opposition was based on the highest motives. The opponents were afraid that if numerous independent schools arose, each with licensing power, and the license recognized by the Provincial Boards, that free trade in diplomas would result, the standard be lowered, and the profession, as a profession, ruined.

As at present constituted, the Medical Boards are entrusted by law with full power to regulate medical education in the provinces, to say what preliminary branches shall be required, of what the curriculum shall consist, and to make such changes as from time to time may seem advisable. When we consider the conditions under which we live, these enactments are in the highest degree advantageous. There are in the Dominion eleven medical schools, many of which are corporations without any control, with faculties irresponsible as regards supervision by trustees, censors, or governors. Even of those which form actual parts of universities, the faculties are partly or altogether independent, and there have been several instances in which, for greater freedom, the benefits of university connections have been sacrificed. The inevitable result of such a state of affairs is keen competition. The students are few, the schools are many; expenses are heavy, receipts are light; human nature is frail—what will follow you know—restrictions are relaxed, special inducements are offered, gradually the standard is lowered, the meshes are widened, examinations become a farce, and the schools degenerate into diploma mills, in which the highest interests of the profession and the safety of the public are prostituted to the cupidity of the owners. The depths to which unlicensed competition will sink the proprietors of some institutions, pass the comprehension of a right-minded person. They will compass heaven and earth to gain students, resorting to measures of solicitation and inducements, various tricks, and artifices which would be deemed doubtful in a grave-yard insurance company. Finally, upon the proprietors of such schools comes a sort of moral paralysis, such a condition as divines call the hardened heart; when, incapable of seeing, much less doing, the right, they believe the system in which they work is a true and good one, and attempts at reformation become well-nigh hopeless. The picture is not overdrawn. Unrestricted competition between numerous schools means free trade in diplomas, and free trade in this sense is synonymous with manslaughter.

From this disastrous condition the medical boards have saved Canadian schools. Bitterly did the colleges fight against increasing the powers of the boards; jealous in the extreme of their chartered rights; and too often eager in obstructing, instead of furthering, useful legislation, they have found, though they did not know it, victory in defeat. The principle is sound and well founded; the united profession of a country or a province should be the guardian of its own honor; greater than the schools, which are but a part of it. The control of all matters relating to medical education and practice may safely be entrusted to its care.

The incorporated body of the profession in each province of Canada is variously known as the "College of Physicians and Surgeons," the "Medical Council," or the "Medical Board," and, as you are all well aware, by the Act of Confederation, each province is left to regulate its own educational affairs. Within the past ten or twelve years, so many important changes have been effected, particularly in the older provinces of Ontario and Quebec, that the boards are gradually approaching a state of efficiency.

As regards education, the ideal board should perform the following duties: 1st. Test the fitness of young men to enter upon the study of medicine; 2d. Order the curriculum in a manner best suited to the country and the requirements of modern medicine; and, 3d. Control absolutely the examinations for the license to practise. Upon each of these points I propose to make a few remarks, referring particularly to existing conditions:

1. Preliminary education and matriculation. In most of the provinces a thoroughly satisfactory system prevails, and a young man, before entering upon the study of medicine, must give evidence that his general education is of such a nature as will enable him to pursue intelligently the study of a learned profession. If the examination is satisfactory, he is permitted to register, and his studies date from this period. A board should control its own matriculation examination, and should accept no other. It is directly responsible to the profession that no incompetent person shall be admitted to study. The check comes lighter to a young man, and is more easily borne at this time than later in his career. The examiners should be independent persons, engaged in general teaching, and there should be at least three or four. No one man can conduct a preliminary examination with entire satisfaction. The organization of the board of matriculation examiners in Quebec should

Digitized by Google

serve as a model for all the other provinces. It was a decidedly retrograde step when the medical council of this province relegated the entrance examination to other hands. And the acceptance of the intermediate High School certificate is not without its disadvantages. We want increasing watchfulness in this matter, and in the interests of higher education the boards should receive the cordial support of all the medical schools in their endeavors to effect an honest and satisfactory standard. That there has been laxity in the past, any one who has had to read many papers at examinations knows only too well. Throughout Canada the subjects for matriculation have always closely followed those recommended by the British Medical Council, and embrace the elements of a good general education, with a fair amount of Latin. To these special subjects have lately been added Natural Philosophy, Chemistry, and Botany (optional). The student has had in the past several difficulties to contend with which should be removed. He has had to pass in some cases two examinations: one before the board of his province, and the other before the university at which he wishes to take his degree. Now the matriculation examination of the boards should be placed on such a level, and conducted in such a way, that any university could consistently accept it in lieu of its own, and if it was universally recognized by the profession, by teachers of high schools, and by the candidates, that there was but one portal of admission to the study of medicine, and that through the medical board by means of its authorized examiners, a great deal of trouble and annoyance would be prevented. Again, in the interests of the student, the greatest care should be exercised in the selection by the examiners of subjects which the candidates will find taught in the advanced classes of the high schools. Similar books to those read for other matriculations should as far as possible be chosen. Lack of attention to these apparently petty details has caused no little irritation on the part of students and teachers.

Let me, then, urge upon you the importance of doing all in your power to put the preliminary education of the student on a good basis; it is in your own hands—insist on competent independent boards, responsible to your chosen representatives; and, what is equally important, impress upon your students and the young men who seek your advice, the need of careful preparation. As a result of some years of observation, I should say that the general practitioners throughout the country are not quite alive to their duty in this matter. Too often young men go up for their examinations imperfectly prepared, and just slip through, to flounder on, hampered at every turn by defective preliminary training.

2. The regulation of the curriculum. The general profession, through its delegates, has an incontrovertible right to regulate and frame the curriculum of study which men shall follow who aspire to join its ranks. The governments allow this right, and have empowered the Boards to frame such measures as they see fit. In the exercise of this function there has been a little friction in the past, and in no one of their duties will the Boards of the various provinces require to proceed with greater circumspection in the future. That there has been a good deal of tinkering, and not always of a satisfactory kind, is a complaint frequently made by schoolmen. That there has been very little and that the results have not been bad, will, I think, be the verdict of any one who looks into the matter fully. The curriculum is at present in a transition stage, and we must expect in the next few years to see important changes, but into these I do not propose to go in detail. One thing is clear, that the Boards and the teaching bodies must act in concert—in the interest of the student and of the profession harmonious action must be arranged. In this country the students of all classes seek the degree as well as the license and are not, as the majority are in Great Britain, satisfied with the latter. Hence the imperative need of a certain uniformity in the requirements of the boards of the universities. The teachers cannot possibly arrange the instruction on diverse plans. The duty of the Board is to lay down a minimum curriculum to which every student shall conform, and which the schools can easily carry out. The university requirements, while as much higher as the authorities chose to exact, should be laid down in the same lines, so that a student could easily proceed in his studies for the one or the other without inconvenience, and the teachers prepare a man for either examination without needless repetitions.

Fortunately the universities and teaching bodies are well represented—too well in Ontario in proportion to the territorial representatives—on the boards, and the introduction and regulation of the necessary changes in the curriculum will fall chiefly into the hands of their delegates, but there are many details which require careful attention on the part of all. The members of the educational committees of the boards have their work laid out for the next few years. Among important questions which await settlement in some of the Provinces are the strict enforcement of the four years of study and the advisability of prolonging the session to nine months, or, what amounts to the same thing, making the summer session compulsory. The plan of allowing a student to pass one of his four years of study with a physician should be done away with at as early a date as possible. For two reasons: in the first place, it is, in a majority of instances, a farce, and we find on inquiry that the student has been pursuing his usual avocation, and perhaps going to a doctor's office in the evening: it is certainly not the equivalent of a session at college. If allowed at all, it should not be the first year, but the third, as permitted in the Province of Quebec, for then a student is in a position to obtain really valuable instruction in practical medicine and surgery from his preceptor. I was surprised, a few years ago, on obtaining the statistics from the registrar of one of the boards, to find how many men there were who passed on the three sessions. In this matter, the boards should not be behind the leading universities, which no longer recognize the year with a physician as the equivalent of a session. And, in the second place, the change should be made in the interests of the schools themselves. On no possible scheme can you arrange a satisfactory three-session course. Either a man pays too much attention to his primary subjects in the first two sessions and leaves the important final branches for one short session, or he tries in his second session to work hard at both and ends in a muddle-pated condition which unfits him for either. The prolongation of the session to nine months, as now exists in some of the schools in the Province of Quebec, must ultimately come

Digitized by Google

in all the colleges. How the foolish habit arose of giving six months' vacation we need not stop to inquire—the folly of it is too evident to need remark; and we can safely predict that within ten years the nine months' course will be universal, either as a continuous session, as at Laval University, or by making the now optional summer session compulsory.

3. The control of the licensing power is the most important function of the medical boards. Acting on behalf of the State, it is their duty to see that all candidates for the license are properly qualified. They stand as the guardians of the public and of the profession, and here their responsibilities are indeed great. In the ideal condition, there should be but one portal in each country through which a man can enter the profession and legally exercise its rights—a uniform standard of qualification to which each one must conform. This is secured in some countries by the direct action of the State, which appoints examiners for the purpose. But a better system is that which we have here reached, in which the State entrusts the incorporated profession with the duty. On this question the hottest battles of the profession have been and are being fought. The universities and chartered colleges have contested, inch by inch, the rights of the profession in this matter, and the struggle has not everywhere concluded. The possession of a degree in medicine from a university, no matter how reputable, cannot on any reasonable ground carry with it the right to registration and practise. The schools are independent bodies, outside, in a large measure, of State, and altogether of professional, control; they are numerous, and the competition between them is close; the requirements for graduation are variable, and the standard of examination unequal. They are close corporations, and neither the public nor the profession ever know what transpires in their councils. In the majority the teachers are also the examiners. Such a state of things can only lead to relaxation, and is fraught with danger to the best interests of all concerned.

A uniform system has not yet been adopted in all the provinces. In too many the possession of a degree, obtained after a proper course of study, still entitles the holder to the license, all others having to submit to examination. In the Province of Ontario the most advanced position has been reached, and the one road to registration is through the examination conducted by a board appointed by the medical council. To this the other provinces must ultimately come. It is what the profession in Great Britain has been striving after for years, and so far striving in vain against the power of corporations and vested interests. In the Province of Quebec the medical board accepts degrees from the local universities to which it sends assessors—after the manner of the British Medical Council, who report on the nature of the examinations. Others than the holders of such degrees must submit to examination. Although this method has not worked badly, it is but a makeshift, and must finally be replaced by a central board of examiners, who shall test the qualifications of all candidates. Unfortunately the prevalent conditions of that province are such that dual boards will be needed, one for the French and one for the English.

In carrying out the details of a central examining board, there are inevitable difficulties which at first cause worry and discontent, but, with patience and mutual forbearance, gradually vanish. The choice of suitable examiners is a delicate matter, and one on which the schoolmen are apt to air grievances more or less just. They certainly should not be selected at random from the members of the council. A few years ago a friend of mine was nominated examiner in chemistry at the Quebec Board. He was a remarkably able practitioner, with a very indistinct and hazy knowledge of chemistry, and it was hard to say who was most uneasy at the examination, Dr. ——— or the students. Teachers in the schools have good grounds for complaint when the Boards select as examiner on special subjects—such as anatomy, chemistry, physiology, and pathology—men who have been for years in active practice without any possibility of keeping their own knowledge on these subjects fresh and practical, and who to "brusk up" require to work as hard, may be, as the poor candidates. With the more practical branches these difficulties do not exist, and the Councils have a wide field for selection. Where special technical knowledge is needed, it would be preferable even to override the law which forbids the selection by the Boards of any teacher as an examiner on his own subject. For the "Staats Examen," in Germany, the professors in different departments are usually chosen by the government to conduct the examination in their special branches. The point is one to which the Boards should attend carefully in the future. They lose the respect of the profession and of the students in nominating as examiners men without special qualifications in certain fields.

The examinations for the license should be made in all respects as practical as possible, but to do this a Provincial Board must possess its own building and appliances, and make arrangements with hospital authorities to have free access to a sufficient number of patients. As the work is done primarily in the interests of the public, it is clearly the duty of the Legislatures to assist in making suitable provision, and it seems probable that Ontario, the first to set the example of a one-portal licensing system, will also be the first to have a local habitation worthy of her incorporated profession. Such a building should contain the paraphernalia necessary for examination purposes. The division into a primary and a final examination, as at present made in most of our universities, and at the Ontario Medical Council, seems the best arrangement. The former embracing anatomy, physiology, general and medical chemistry, and materia medica; the latter, the practical branches of medicine, surgery, and midwifery. In practical details the "Staats-Examen," of Germany, might in many particulars be followed.

A serious difficulty has been felt in conducting the examinations satisfactorily as regards time, place, and rapidity. They should come off after the university examinations have been completed, and not, as now, immediately at the close of the session. More time could then be given, which will be necessary if the tests are to be made more practical. As the number of candidates increases, the examiners on each branch should be doubled. One centre in each province should be chosen for the sittings of the Board, and in almost each instance this will be the chief town. To go to Quebec for one meeting and Montreal the next,

Digitized by Google

as is the practice in the Province of Quebec, and to hold an examination in Kingston as well as in Toronto, are touching and tender tributes to age with which a harder generation must soon dispense.

Very much more time must be hereafter given to those practical portions of the examinations which afford the only true test of a man's fitness to enter the profession. The day of theoretical examinations is over.

Permit me to refer to one or two other questions in connection with the medical boards. An anomaly which has been the source of no little irritation results from our close connection with the mother country. Any registered practitioner of Great Britain under the present British act can claim registration in the colonies without further examination. For some years Ontario contested the right, but it was finally settled by the registration of Dr. E. St. G. Baldwin, in 1879, and Dr. A. E. Mallory, in 1880, since which time many have been entered on the register without examination. The Medical Bill which was shelved last year in the House of Commons contained a clause permitting the colonies to make any regulations they pleased concerning registration, and doubtless a similar proviso will appear in any future bill. The objections to receiving British registration are precisely those made against the reception of Canadian registration in Great Britain. The examinations are conducted by corporations with varied standards, of whose proceedings nothing is known, and over which no control can be exercised. But in Ontario the shoe pinches badly in another way. After graduating, students are enabled to give the Board the slip by taking an English or Scotch qualification, and registering in Great Britain, when they return and are entered upon the register without further examination. The objection to this lies in the fact that many men have evaded the just regulations of their province and returned with British registration, when even they could not have qualified for examination at the Ontario Medical Board. With few exceptions, Canadians seek in Great Britain the easier qualifications, particularly the license of Edinburgh Colleges. At some of these the custom has been with Canadian graduates to examine the parchment, accept the University degree, and admit the candidate to examination without any further inquiry. To avoid an injustice, the British licensing bodies must examine the matriculation certificate, and have satisfactory proof by class tickets that a student has spent four years in the study of medicine. Under these conditions registration in Ontario on a British certificate would be no hardship, though there would still be the unfair discrimination against the local institutions.

Through the kindness of Dr. Pyne, the Registrar, I am able to give you some figures bearing on this question. In the past five years 378 men have registered in the Province of Ontario, and of these there were 93 Canadians, who did so on their British registration; that is to say, about one-fourth of the number have avoided the enactments of the Board by proceeding to Great Britain and passing at one of the Colleges. No one can doubt that these 93 men were greatly benefited by the period of additional study and by contact with men of other schools and countries, but they would have been still more benefited if they had first conformed to the requirements of their own province, and aided the profession in maintaining regulations the benefits of which are universally recognized.

The fees demanded by the boards excite a good deal of grumbling on the part of students and practitioners. A sum of $70 is charged by the Ontario Board for the three examinations, matriculation, primary, and final; and in Quebec the registration fee is $20, and the matriculation $10. It is the old story, those who are best treated often complain the most. In the matter of fees, the medical students of Canada are in too easy a position, and they must expect changes in the near future. While the expenses of conducting a medical school have quadrupled in the past twenty-five years, the fees have not increased ten per cent. The charges of the boards are just and reasonable, as well as necessary to meet expenses. The annual tax on physicians of $1 in Ontario and $2 in Quebec, is often spoken of as irksome, but surely it is a trifling contribution to the general welfare of the profession.

It seems extraordinary to outsiders that in a country like Canada, with scarcely five millions of inhabitants, there should be so many licensing boards, and a still greater anomaly, that a licentiate in one province cannot practise in another—that there should be no reciprocity. So it seemed also to many earnest minds a decade or so ago, when in this Association a strong attempt was made at several meetings to frame a Dominion Medical Bill. It failed, as will, I think, subsequent ones, should they be made. Only one remedy remains, the boards of the various provinces may in time so assimilate the curriculum and examinations that reciprocity may become possible, but this we cannot expect for some years. For certain purposes a Dominion Registration Bureau at Ottawa seems specially indicated; thus the surgeon of a Quebec regiment doing duty in Ontario would be practising illegally, and in the marine, the surgeons sailing in the passenger steamers must be registered in the province of the port from which the vessel hails. There would be great if not insuperable objections raised to any such bureau, though it might be feasible to devise a plan for the military surgeons and those belonging to the mercantile marine.

I have dealt thus fully with the constitution and functions of the medical boards of the provinces, because I feel convinced that the safety of the profession rests with them. Of inestimable service in the past, their work in the future will be even more beneficent. Do arouse to a sense of your professional advantages. Where else do the medical men of a country enjoy the rights of conducting their own affairs in their own parliament? Look at Great Britain, where our mighty sister Association, with all her influence, and backed by eleven thousand members, could not force the principle of professional representation into the last medical bill, and at the best was only able to secure three or four members from the profession at large. Rest content, when in each Province of this Dominion you have (1) an elective representative assembly (medical board, council, or college), with members from each teaching body; (2) absolute control of preliminary qualifications, curriculum, and examinations for the license to practise; (3) appropriate accommodation for the meetings of the boards, for the conducting of examinations, and for preservation of the local and general archives of the

Digitized by Google

profession. The full development of the Acts of 1788 and 1815 will not be reached until these things are accomplished. The first two you have already won in a majority of the Provinces, the last will perhaps be the most difficult of accomplishment; but I feel confident that the day is not distant when in the capital of each province the incorporated profession will have a stately Æsculapian temple worthy the traditions and aspirations of our high calling.

And here I may reasonably conclude this portion of my theme, which is concerned particularly with the relations of the profession to the community, but I will dwell upon one point. I began by saying that in a well-ordered State every citizen should feel that he has near at hand well-trained men, to whom in the hour of need he may turn with confidence, and ask aid for himself, his wife, or his little ones. That throughout Canada this condition exists, that the community is to-day served by capable and well-trained men, that within reach of the poorest in our smallest villages there is an honest, capable physician, that impostors and charlatans are few; these, gentlemen, are some of the blessings for which we may, lifting both hands to heaven, thank our Medical Boards.

To another important relation of the medical profession to the community I can but briefly refer. One of the most remarkable developments of modern medicine has been the direction of the study of the causes and mode of prevention of epidemic diseases. The principles of preventive medicine have been gradually receiving due recognition on the part of the public, and the necessity for organized effort is generally acknowledged. In this province the effort has resulted in the establishment of the Provincial Board of Health, which is doing a great work, and should receive the active support of the public and the profession. The successful course which it has pursued during the past four years affords a stimulus which the other provinces must sooner or later feel, and sets an example which for very shame they must follow.

2. The medical school. In the progress and development of a profession, the medical school plays an important and essential part. The primary object is the training of young men in the science and art of medicine, to supply the community with fit and proper persons to take charge of the sick and injured, and it is with this aspect of a medical school that the public is naturally concerned. In most European countries the State, as guardian of the public weal, undertakes the control of medical education and subsidizes largely the medical faculties of the universities. In Great Britain this is also done to a slight extent, but everywhere on this continent the schools have arisen as a result of private enterprise. The origin and evolution of the medical school in this country are quite easy to trace. For many years private tuition was the sole means of obtaining a medical education, and the system of apprenticeship prevailed to a large extent. In a series of "grinds" or "quizzes" the preceptor would take his pupils over the whole range of medicine and surgery, and a knowledge of anatomy was obtained by private dissection, which was carried on extensively. The office practice and the daily round furnished clinical material. The student was much with his preceptor, became his friend and companion, and in the course of four or five years, sometimes less, grew really very proficient in the practical working of his profession, and felt prepared to present himself before the Provincial Board. Some of the very best practitioners we have had in Canada received their medical education in this way. Take the Medical Register of Ontario or Quebec and seek out the names of the men which have simply Lic. of the Med. Bd. of Upper Canada or of Lower Canada after them, and we find among them many of the men we know best and respect the most highly. Without doubt, in good hands, the old system had great advantages; the essential, useful, and practical details of professional life were well taught; for the refinements and superfluities, the busy physician found no time. Among the private teachers before medical schools became generally accessible, were some notable men whose names deserve to be mentioned in grateful remembrance. Dr. James Douglass, of Quebec, was a remarkably successful as well as popular teacher, and his pupils had the great advantage of the Marine Hospital. He still lives in peaceful retirement, one of the few links uniting the profession of Quebec to a generation long past. The late Dr. Rolph, from the date of his removal to Toronto in 1831 until the foundation of the Toronto School of Medicine in 1843, was one of the most energetic and successful private teachers, and many of his pupils of that date now occupy prominent positions among us. Even after the troublous times of 1837, when he had to cross the border, the students followed him to Rochester.

The organization of the first medical school arose from the association of two or three men engaged in private teaching, who thought that it would be more advantageous, and save time, if each one taught one or two branches. In 1824, at Montreal, Drs. Stephenson, Holmes, Caldwell, and Robertson gave the first definite course of lectures in medicine delivered in this country. This "Medical Institution," as they called it, became, in 1829, the medical faculty of McGill College, and remained for many years the only medical school in the country. The next attempt was a much more ambitious one. As early as 1835–6 efforts were made to induce the government of Sir John Colburn to establish a faculty of medicine in King's College, Toronto, and elaborate plans were prepared, but nothing came of it until 1843, when a faculty was organized with a full and able staff. A more favorable inauguration of a medical school could not have been devised; with State aid, well-trained and efficient professors, who were in the receipt of salaries ranging from £225 to £350—fine emoluments for those days. From all I can gather, the school was a thoroughly efficient one, and did good work in medical education, but the professors made certain mistakes for which they paid heavily. In opposing the incorporation of the Toronto School of Medicine, which had been organized by Dr. Rolph in 1843, they acted most injudiciously, laid the foundation of future trouble, and too many of them were hostile to the profession in their desire for a better medical act. After an existence of ten years, an act of the Legislature left the University of Toronto with only the academical department, and swept away a medical school which, whatever its faults, had in it the elements of ultimate success, and left the profession and the public at the

Digitized by Google

mercy of irresponsible schools without foundations and dependent on private enterprise. There can be no doubt that the abolition of the faculty of medicine of the University of Toronto retarded seriously the growth of the profession in this country. The establishment of a well-equipped institution would have been an example and a stimulus to others, and as years passed, the difficulties inevitably associated with the first few years of existence would have vanished.

In 1843 the Montreal School of Medicine and Surgery was founded, and continues as the largest French school in the Dominion. About the same time the St. Lawrence School was started in Montreal in opposition to McGill College, but it had a short life and soon expired. The Quebec School of Medicine next started and become, and continues as the medical faculty of Laval University. In Toronto a third school was added to the existing ones in 1850 by the establishment of the Upper Canada School of Medicine, which, in its first session, became the medical faculty of Trinity College, and after an existence of three or four sessions, ended by the resignation of the professors who refused to submit to certain vexatious test enactments of a religious nature demanded by the corporation. The faculty of medicine of Victoria College was next established in Toronto, for years known as Rolph's School; it terminated its existence in 1869. The Kingston School, organized as a faculty of Queen's University, is now known as the Royal College of Physicians and Surgeons. The faculty of medicine of Bishop's College, Lennoxville, P. Q., was organized in Montreal in 1870. In the same year the faculty of medicine of Trinity College was reorganized and exists now as a separate corporation known as Trinity Medical School. The Medical School at Halifax is the only one which has been started in the Lower Provinces.

The most recent additions to our list have been the Branch of Laval Medical Faculty at Montreal, 1877; the faculty of medicine of Western University, London, Ont., and the faculty of the University of Manitoba, both organized within the past few years; and in 1883, as the outcome of an unfortunate contretemps at Kingston, a School of Medicine for Women was started in that city, and followed by the establishment of another for the some purpose in Toronto.

Of this latest development, there cannot but be a feeling of regret that our friends in these cities should have entered upon undertakings so needless in this country. It is useless manufacturing articles for which there is no market, and in Canada the people have not yet reached the condition in which the lady doctor finds a suitable environment. Look at the facts as they are; even the larger cities can only support one or two; in fact, Quebec and Montreal have none, and in the smaller towns and villages of this country she would starve. For the sake of educating six or eight women annually, of whom at least three or four will go abroad, two more medical schools have been established with full staffs of professors and teachers. We can but hope that at the expiration of the five years for which kind friends have guaranteed the expenses, the promoters of these institutions will be in a position to place their energies and funds at the disposal of the schools devoted to the sterner sex. Do not understand from these remarks that I am in any way hostile to the admission of women to our ranks; on the contrary, my sympathies are entirely with them in the attempt to work out the problem as to how far they can succeed in such an arduous profession as that of medicine.

Exclusive, then, of the schools for women, there are existing eleven teaching bodies throughout the country, three French and eight English, a goodly number to supply the wants of about five millions of people. In Great Britain, with a population of thirty-five millions, there are about 34 medical schools, and in the United States, with a population of fifty millions, there are 139 schools conducted in the interests of the regular profession, so that in comparison with these countries we are very abundantly supplied.

The youngest among us may have watched the incubation and birth, and many of us the gradual growth and development of a medical school. With scarcely an exception every one which has started owes its origin to the individual exertions of members of the profession. There are men present who could tell us that the task is not a light one to-day, but what must it have been to those who began the work fifty or sixty years ago? It was an unending struggle against serious obstacles and difficulties. Money had to be raised for buildings and apparatus, and with but few students and small returns, the marvel is not that only four have succumbed in the struggle, but that so many have survived. The internal difficulties are often the most serious; the brunt of the work in such enterprises always falls on one or two zealous men who have to carry the chief part of the load, and the dead weight of lethargic colleagues has been the heaviest burden to many an ardent spirit.

Debt is the millstone which keeps the young schools under for many years; borrowed money furnishes the appliances, etc., and even in the older schools each addition to the buildings means so much more interest to pay. In only one or two of the faculties connected with universities have the governors even furnished suitable accommodations. The financial condition is for years oppressing, and from session to session the school drags on, living from hand to mouth, barely able to meet liabilities and pay the teachers—at this stage most probably not at all. As the number of students increases so do the finances improve, and, if a school proves popular, the debts may be paid off and the professors receive fair remuneration, but, so long as the attendance is limited, the receipts are only such as will barely meet the expenditures. A difficulty which under the present circumstances seems insuperable, is the fact of absolute dependence for success upon the number of students; small classes mean restricted capabilities for teaching, spiritless instruction, low-spirited professors, and general discontent, particularly on the part of the faculty. Large classes mean perhaps the opposite of all this, but not always; still there is a cheeriness about a professor the benches of whose classroom are well filled. I have known a small entry depress for the session the spirits of a man whose estimation of everything was numerical.

Let us glance at the facts as they stand. I estimate that last season there were in the eleven Canadian schools about 900 students, from whom, with trifling ex-

Digitized by Google

ception, the entire support of the institutions was derived. Four of the eleven institutions are greedy enough to attract at least 700 students, leaving about 200 to be divided among the seven other schools. With the low scale of fees at present in vogue, I doubt if each student paid more than an average of $80 per annum for instruction, so that the total receipts at the number of students above mentioned would be about $70,000, of which at least $55,000 goes to four of the schools, leaving a balance of not more than $15,000 to be divided among the remaining seven. Now, a modern school of medicine is a serious affair to undertake and equip; there are branches to be taught which require, even in the smallest schools, plenty of room and good apparatus. Laboratories for the practical teaching of chemistry, histology, anatomy, pathology, and physiology must be provided, and arrangements made for library and museum purposes. Personal expenditure on the part of members of the faculty can alone supply these in some of the schools, and in almost all the rule has been that each lecturer from his fees shall provide his own teaching outfit. Where the teacher has enthusiasm and a purse this may work well, and indeed does so sometimes, for I know of an instance of an outlay of over two thousand dollars in apparatus, and of another in which the personal laboratory expenses were always between five hundred and one thousand dollars annually. As matters have been in our schools heretofore, without personal expenditure laboratory equipment has been defective. The remarkable impetus which has been given of late to practical teaching has increased very much the expense of conducting a school, for not only have the laboratories to be provided, but special men must be forthcoming with special training. The general practitioner who has for eight or ten years been busy at practical medicine and surgery may step into the professor's chair and give a good, sensible course of lectures; but to conduct laboratory work demands careful and prolonged training, which costs much money, and when obtained has a market value.

One great evil which results from this condition is the competition for patronage among the schools, which I have already alluded to as a danger to be carefully watched by the profession. Too many of the students enter upon the study before they have means sufficient to carry them through the entire course, and they seek special inducements, reduction in fees, exemption from attendance until Christmas, and will often in letters set off one school against another in a most amusing way. Think, gentlemen, to what the unrestricted competition among eleven schools for 900 students might bring the profession! It would be a struggle for existence in which the public and the profession would certainly be the losers, but with the wise regulations already referred to, existing in each province, the competition is reduced to reasonable limits, as all students, irrespective of their schools, must virtually pursue the same plan of study and for the same length of time.

What is the remedy? The small schools have rights equally with the large; they cannot be asked to immolate themselves in the interests of more favored institutions. It is plainly within the duty of the provincial boards to inquire into the equipment of the teaching bodies, and they should refuse recognition to those which have not appliances fit to conduct a modern medical course; or, what would be better still, the medical boards should have the power of prohibiting the establishment of a new school until satisfied that its promoters had money sufficient to begin such an enterprise, and had suitable buildings and hospital accommodation. In the future one of two things will take place: either a considerable number of the small schools will die of starvation—for it is quite evident on the above financial statement, which is approximately correct, that there are seven existing on class fees which could only support one, and that in a not very flourishing manner—or means must be devised to secure funds from other sources. That there are superfluous schools in the country, no one can deny, and the death of three or four under present circumstances would be no loss to the profession or the public; but if all could be furnished with suitable clinical and scientific equipments, they would then prove a source of strength, not of weakness. Dependent solely on class fees, the smaller schools, even with the self-sacrifice of professors which I know of in many instances, cannot hope to keep up with the modern requirements in medical teaching, and the larger schools, with their increased expenses and increased salaries, are really not much better off. The time has come when we should lay clearly before the public the needs of higher medical education. The full development of a school cannot be reached without extraneous aid. To build laboratories and provide costly apparatus require sums quite outside the power of the faculties or the professors to supply. We should learn a lesson from our brethren of the clergy. Ask in Toronto and Montreal the purpose of so many beautiful and costly buildings clustering about the universities of these towns, and we are told they are the divinity schools, in many instances erected at the cost of individual donors. The number of men in this country is rapidly increasing who have money to give where they see it is needed and will be profitably employed; and if those interested in medical education bestir themselves actively, suitable endowment can be obtained. We have not asked before—in careless unconsciousness of our needs—but we must ask now and ask earnestly. The successful appeal for $100,000 made last year in Montreal is at once an indication and an encouragement. There are strong, enlightened men among us, like the Hon. Donald A. Smith, who feel, with Descartes, that the hope of the amelioration of many of the ills of humanity lies within our profession, and that it is a public duty and privilege to assist in making our colleges true seats of learning, as well as schools of sound instruction.

3. The medical society. In a young country the organization of medical societies is associated with serious difficulties. In cities practitioners can easily meet together, but in communities scattered over a wide extent of territory, like Canada, general societies are not readily established. Thus we find that several attempts were made to organize a Canadian Medical Association, but without success until the confederation of the provinces in 1867. In 1845 the Medico-Chirurgical Society of Montreal sought to secure a Provincial Medical Association, and called a conference of delegates from the societies in the city and district of Que-

Digitized by Google

bec, and the district societies of Niagara and Toronto. A meeting of the delegates was held on the 20th of August, but the scheme was unfortunately frustrated. In 1850 the same Society again sought to unite the profession of Canada in a British-American Medical and Surgical Association, and on July 10th, at Three Rivers, a preliminary meeting was held, at which a constitution and short code of by-laws were adopted. Dr. Morin, of Quebec, was elected President, and Dr. Hall, of Montreal, Secretary, and the first general meeting was arranged to take place in Kingston on the second Thursday of May, 1851. I do not know that it was ever held; the journals of the day are silent on the subject.

At the instigation and call of the Quebec Medical Society, a meeting was held at Laval University on October 9, 1867, to consider the advisability of establishing a Canadian Medical Association. The organization was successfully effected, and the first meeting was held in Montreal in 1868 under the Presidency of Doctor, now Sir Charles, Tupper.

Among the objects which the promoters sought to effect by united effort was satisfactory and harmonious medical legislation, and we find that, for the first four sessions the time of the Association was chiefly occupied with the framing of a Dominion medical bill, which ultimately proved an impracticable measure, and was dropped. The subsequent meetings have been devoted to more legitimate topics of discussion, and we have reached a truer conception of the objects of our annual gatherings. We are all agreed, I think, that the highest work which an Association such as ours can undertake is the promotion of the scientific and practical aspects of the profession. To these meetings the best minds among us should bring their best thoughts, that, by the reading and discussion of papers, we may be mutually benefited. Every member can bring something. One great attraction in our profession is its freshness and novelty. Each one of us has had, since our last meeting, opportunities for the study of problems in disease, new, perhaps unexpected, and which may not occur to us again. Material for original work and research lies in the daily round of each one, awaiting only the spirit of patient and earnest inquiry, lacking which we cannot wonder that men deem the practice of medicine dull, stale, and flat. Every one should come to learn, and of necessity brings with him something he can teach, for in certain points his experience supplements what is wanting in another's. To our gatherings all teachers in our schools should come to meet their brethren and give to them an account of their stewardship—for do they not hold their positions in trust?—and show by their work and ways that they merit the confidence reposed in them. The more we foster the scientific features of our gatherings, the more succes ful will the Association be. It has been so with our sister associations in Great Britain, and in France and Germany the corresponding societies form sections of the general associations for the advancement of science, and the meetings are devoted exclusively to work.

By no means the smallest advantage of our meetings is the promotion of harmony and good-fellowship. Medical men, particularly in smaller places, live too much apart and do not see enough of each other. In large cities we rub each other's angles down and carrom off each other without feeling the shock very much, but it is an unfortunate circumstance that in many towns the friction, being on a small surface, hurts; and mutual misunderstandings arise to the destruction of all harmony. As a result of this may come a professional isolation with a corroding influence of a most disastrous nature, converting, in a few years, a genial, good fellow into a bitter old Timon, railing against the practice of medicine in general, and his colleagues in particular. As a preventative of such a malady attendance upon our annual gatherings is absolute, as a cure it is specific. But I need not dwell on this point—he must indeed be a stranger in such meetings as ours who has not felt the glow of sympathy and affection as the hand of a brother worker has been grasped in kindly fellowship.

There is special need in this country for such an association. With scattered and isolated provinces, self-governing, and regulating their own affairs, this organization is the sole bond of professional union. At these meetings we are neither of Ontario nor Quebec, of Manitoba nor Nova Scotia, but of Canada, and the narrower provincial spirit is lost in a wider national feeling. In the future development of the profession this body must take an ever-increasing share. It has difficulties to contend with of a geographical nature, as the distances between our provinces are so great, but these must not be considered. A peripatetic association always labors under certain disadvantages, but these we have in common with similar bodies in other countries. The provincial medical societies which have been established, supplement the work which we do and are a source of strength. We regret that there are still one or two provinces without such organizations. The district societies throughout the country are becoming more and more vigorous, and physicians are everywhere recognizing the advantage of coöperation in the study of our profession.

Let me refer to two other matters in conclusion. In selecting the place of meeting the Association should be guided by what is thought best for the interests of the profession, and it should be distinctly understood that when we meet at any place the sole business of the local profession is to arrange suitable accommodation; and this Association must set itself strongly against past practices by which the profession of a place has been heavily taxed for entertainment. In this we should follow the custom of the British Medical Association, at the meetings of which all the members subscribe to the association dinner; and I should ask for the reappointment of the committee to revise the by-laws and constitution, as there are certain changes which will facilitate the work of our meetings and which should be brought up for discussion at as early a date as possible.

And now, gentlemen, I have done, and there remains but the expression of my thanks for the kind attention you have given to a very matter-of-fact address, but I cannot part with you on this occasion without assuring through you, my brethren in Canada that, although no longer of them, I am still with them in spirit, with them in their persistent efforts to advance the higher interests of our profession, and united with them by a thousand bonds of fellowship and friendship, which absence shall not weaken nor time efface.

ZINC CHLORIDE.

BY GEORGE H. ROHE, M.D.,
PROFESSOR OF HYGIENE IN THE COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE.

IN his classical essay on disinfection,[1] Koch expresses astonishment that an agent, which proved almost entirely inefficient as a germicide in his experiments, should have obtained the widespread reputation as a disinfectant which chloride of zinc enjoys. He shows that anthrax spores, exposed to the action of a five per cent. solution (1 : 20) of this salt for thirty days, germinated as freely upon a suitable culture medium as similar material not so exposed. The development of micrococcus prodigiosus was only slightly retarded by exposure for upwards of sixteen hours to a one per cent. (1 : 100) solution. Anthrax spores developed freely in a one-tenth per cent. (1 : 1000) solution of this salt.

Mr. A. W. Blyth[2] says, a one per cent. (1 : 100) solution seemed to stimulate the growth of anthrax spores; five per cent. (1 : 20) failed to destroy their vitality; while twenty-five per cent. (1 : 4) seemed to arrest the life of the spores.

Dr. Sternberg[3] found two per cent. (1 : 50) destructive of the micrococcus of gonorrhœal pus; while one-half per cent. (1 : 200) destroyed the power of development of the septic micrococcus. In Sternberg's later experiments[4] ten per cent. of Squibb's liquor zinci chloridi (said to contain fifty per cent. of anhydrous chloride of zinc) was found effective in destroying the organisms of broken-down beef-tea. Numerous experiments have shown that these organisms are fully as resistent to most germicides as are the spores of B. anthracis. In order to clear up the apparent discrepancy between these observations of Koch and Sternberg, an additional series of experiments has recently been made by the latter, assisted by Dr. A. C. Abbott. These experiments showed that the spores of B. anthracis are not killed by an exposure for two hours to a ten per cent. (1 : 10) solution of this salt. A five per cent. (1 : 20) solution, acting for the same period was, however, effective in destroying the spores of B. subtilis, and upon broken-down beef peptone solution, which had been freely exposed to the air, and consequently contained a variety of microörganisms. A two and a half per cent. solution (1 : 40) failed to sterilize putrid beef-peptone solution.

The above experiments indicate that zinc chloride, in the proportion of five per cent. added to the material to be disinfected, can be relied upon for the destruction of microörganisms in the absence of spores. To destroy the vitality of anthrax spores, however, a twenty per cent. solution is necessary.

CASE OF STRYCHNINE POISONING TREATED BY THE EXTRACT OF WILD CHERRY BARK, CHLOROFORM INHALATION, ETC.; RECOVERY.

BY GEORGE M. KOBER, M.D.,
A. A. SURGEON, U. S. ARMY.

THE following extract from a letter from Lieut. J. A. Hutton, U. S. Army, dated Berkeley, Cal., January 22, 1885, recalls to my mind a case of strychnine poisoning, which is, perhaps, of sufficient importance for publication:

"If my memory serves me, I once heard you speak of a treatment for poisoning by strychnine by administering extract of wild cherry bark. Can you refer me to the article on the subject, or give me any examples of the use of the extract in such cases?"

The following is my reply:

I have been looking for the article you refer to, but without effect; my impression is, that I received my first suggestion of the use of hydrocyanic acid in strychnine poisoning from the *American Journal of the Medical Sciences*, either in 1870 or 1871, and about three years ago from some Kansas medical journal, which had been sent to me as a specimen number. This must have been in December, 1881, for, on the 21st of December a case of strychnine poisoning occurred in a Chinaman at this place; the symptoms were well pronounced, and after washing out the stomach, I administered a tablespoonful of the extract of wild cherry bark, and repeated the dose in twenty minutes; the tetanic paroxysms diminished in frequency and force, and were readily controlled by the inhalation of chloroform. The alarming symptoms in the case lasted, however, nearly two hours, yet there was evidence of progressive improvement, and the immediate effect of the wild cherry pointed to an antagonistic action. After the expiration of two hours, the only remaining symptoms observed were involuntary twitches and a feeling of stiffness in the muscles, for which potass. bromide and chloral were given with good effect; 15 grains of the former and 10 grains of the latter soon induced rest and sleep for a few hours. The patient recovered perfectly in two days, complaining only of being tired during this time.

My reason for not publishing the case before, was the insufficient evidence of the fact that the extract of wild cherry bark proved absolutely antagonistic to the action of strychnine. You will observe that the stomach had been thoroughly evacuated, the quantity of the poison introduced was unknown, and the effects of chloroform inhalation cannot be overlooked.

I have seen in recent years no authority of weight for the use of hydrocyanic acid in strychnine poisoning, but the subject is sufficiently important to experiment on animals and thus determine whether the extract of wild cherry bark possesses advantages over

Digitized by Google

prussic acid, and I hope you have the time and facilities at the University Laboratory to make this subject, as well as the antagonism of strychnine and woorara, tobacco, chloroform, chloral, calabar-bean, potassium bromide, camphor, tannin, morphine, apomorphia, atropia, nitrite of amyl, and carbonic acid, a basis for experimental research and report. The action of apomorphia in strychnine poisoning has been but little studied and may prove of special value. I know of only one instance in which it has been used (*vide American Journal of the Medical Sciences* for April, 1878, page 448).

At all events, such experiments intelligently conducted and honestly reported, will be of great value and are highly appreciated by the profession. Of course, this field has been worked by others, but I doubt whether very many experiments of this nature are repeated sufficiently often by independent observers. I believe we are too apt to accept the conclusions of others as our own. The labors I suggest will either prove or disprove the work of others, and as such, will possess merit and receive due credit.

The above correspondence conveys all I have to say on the case, and is submitted without further comments.

FORT BIDWELL, CAL., Jan. 28, 1885.

MEDICAL PROGRESS.

THERAPEUTICS OF JABORANDI.—M. PETITHAN, in a paper upon the therapeutic uses of jaborandi, claims its efficacy in the treatment of the following diseases:

1. In all catarrhal and rheumatic affections, subacute or chronic, whatever may be their localization.
2. In all dropsical conditions, without alteration in the kidney, when anæmia is not too marked.
3. In certain cases of pernicious intermittent fever in which reaction is hastened without affecting the action of quinine.
4. In malignant febrile exanthemata, especially in scarlatina.
5. In diseases of the skin, characterized by dryness, psoriasis, etc.
6. In chronic syphilitic disease during the employment of mercury and the iodides.
7. In mercurial intoxication.
8. Probably in diphtheria.

The remedy, according to M. Petithan, should be used as follows:

1. It should be administered the patient fasting.
2. The dose should vary according to the case, 60 grains being an average quantity.
3. The temperature of the infusion should vary according to the degree in which the sudorific effect is desired.
4. A local temperature of at least 66° F. should be constantly maintained.
5. The patient should not be permitted to leave his bed on any pretext unless well covered, in order to avoid variation of temperature and syncope, which may result therefrom.
6. Warm drinks should be administered, if the patient is thirsty, a condition very rare owing to the salivation produced by the drug.
7. The employment of a good quality of the drug, that of Coutinho being the best.
8. To have at hand stimulants such as ammonia, etc., to sustain the patient.
9. If necessary to administer an antidote; M. Petithan suggests the employment of belladonna.—*Bulletin Général de Thérapeutique*, July 15, 1885.

STRETCHING OF THE LIGAMENTS OF THE KNEE-JOINT OF A CHILD AS A RESULT OF VERTICAL EXTENSION IN FRACTURE OF THE THIGH.—DR. GEORGE FISCHER, in the *Deutsche Zeitschrift für Chirurgie*, reports a case of stretching of the ligaments of the knee-joint of a child by vertical extension applied in a fracture of the thigh.

The patient, a boy six years of age, was treated for fracture of the thigh by suspension of the limb, and the application of an extension weight of six pounds. Twenty-four hours subsequent angular dislocation of the fracture being observed, an additional weight of five pounds was added to the extension weight, with the result of bringing the fragments into position.

The child remained without pain or fever, and was cheerful. In four weeks the dressing was removed, but the child was unable to stand upon the right leg, and on making the attempt shrieked with pain. Examination showed the fracture to be perfectly united, and also that there was abnormal mobility of the knee-joint. The motion at the joint, both backward and forward, in abnormal extension, was easily made, while, at the same time, the exaggerated motion of the joint was easily heard and felt; and when the foot was raised the leg was placed in such extreme hyperextension that the popliteal space lost its concavity and became convex. Bending the knee produced extreme pain. The circumference of the right knee was two-fifths of an inch greater than that of the left.

The patella was movable, and no effusion was recognizable in the joint. One bandage was applied extending from the foot to the middle of the thigh. In two weeks the child arose from bed and walked about. Two weeks later the bandage was removed and the joint was found entirely normal.

The history of the case shows, beyond doubt, that the abnormal mobility of the joint was due to stretching, not to rupture, of the lateral and cruciform ligaments. The latter condition undoubtedly would have occasioned an extracapsular effusion of blood, or have produced protracted weakness of the joint, since even when the cruciform ligaments alone are concerned, the latter persists through many months, and even years.

TREATMENT OF PHTHISIS.—The unsatisfactory state of the treatment of phthisis and the position of M. Germain Sée as a practical physician may be regarded as sufficient reasons for a reopening of the investigation of terpine as a therapeutical agent. A careful account of M. Sée's study of the subject may be perused in the *Bulletin de l'Académie de Médecine*, No. 30. Terpine is believed to be a powerful agent in modifying the respiratory mucous membrane, and in diminishing morbid secretions. It is said to diminish, and even to cause to disappear altogether, the purulent secretion of catarrhal forms of phthisis. The muco-purulent secretion that proceeds from the bronchial tubes irritated by tubercles and that which comes from the walls of pulmonary cavities are the indications for the use of terpine when-

Digitized by Google

ever these secretions are sufficiently abundant to exhaust the patient. Terpine is useful in the hæmoptysis of incipient tuberculosis—that is, before the development of cavities with aneurisms in their walls. In the treatment of catarrhal pneumonia and chronic bronchitis, independent of asthma, that only induce dyspnœa by plugging of bronchi, terpine constitutes the best means of lessening the bronchial hypersecretion. Its prompt action and freedom from disagreeable physiological effects ought to make it a preferable preparation to those containing impure forms of turpentine. On account of its perfect harmlessness and easy digestibility it has advantages over creasote. The best method of administration is in the form of a pill, or as an alcoholic preparation; the most convenient dose is one gramme. In nervous asthma, whether emphysematous or catarrhal, iodine and pyridine are incomparably superior to terpine. Terpine is a derivative of turpentine; it is the binhydrate of turpentine, and may be represented by the following formula: $C_{20}H_{16}(H_2O_2) + 2(H_2O)$. It is formed by the direct union of its component elements when turpentine is allowed to remain in contact with water.—*Lancet*, Sept. 5, 1885.

INFLUENCE OF THE SUN UPON THE GROWTH OF THE SPORES OF BACILLUS ANTHRACIS.—ARLOING, at a recent meeting of the Académie des Sciences, made the following report of his researches upon the influence of the sun upon the vegetability of the spores of the bacillus anthracis. The investigations were conducted as accurately and precisely as possible, and Arloing concludes:

1. If by vegetability is meant the power which the sporiferous mycelium or the free spores possess of producing a new mycelium, it is evident that this is rapidly suppressed by the heat of a July sun in bouillon in which recent cultivations have been made. Exposure for two hours to a temperature ranging from 95° F. to 102.2° F., was sufficient to produce such result.

2. When the influence of the solar heat is exercised less than two hours, vegetability is simply suspended.

3. The effect produced is the result of the solar rays, per se, varying with their intensity, and is the result neither of the calorific rays of the spectrum nor of the luminous rays.—*Gazette Hebdomadaire de Médecine et de Chirurgie.*—August 28, 1885.

A CASE OF CHRONIC PARENCHYMATOUS NEPHRITIS CURED BY THE SUBCUTANEOUS INJECTION OF PILOCARPINE.—DR. J. LAZARUS reports a case of chronic parenchymatous nephritis cured by hypodermatic injections of pilocarpine.

The patient, when first seen by Dr. Lazarus, May 11th, had been ill several months, and his entire body was swollen and shapeless. The legs, belly, and scrotum were enormously distended, and the last was attacked by superficial gangrene. Both buttocks, both thighs, and both legs, as well as both feet, were the seat of pus-discharging ulcers, due to phlegmonous inflammation of the subcutaneous cellular tissue. A bedsore in the sacral region added to the pain and discomfort of the patient. Great difficulty in breathing was also experienced, and profuse diarrhœa was present. The urine was scanty, and had a specific gravity of 1040, and in consequence of the great amount of suspended material, composed of epithelial scales, detritus, etc., was cloudy, and even before the boiling point was reached was converted into a stiff jelly.

On inquiry it was learned that the present condition began entirely unnoticed, and that in February the swelling of his feet led him first to seek professional advice. Continuing his employment until April, he was at last compelled to remain in bed, owing to the increased swelling of his feet and to extreme weakness, and to subject himself to systematic treatment.

Treatment consisted in the employment of hot baths and in the medication generally employed in the treatment of Bright's disease, but no improvement resulted. Dr. Lazarus at once determined to resort to the hypodermatic use of pilocarpin. Previous to the administration of the drug, a small quantity of brandy was given to support the heart, and followed by the injection into the thigh of one-third of a Pravaz's syringeful of the following:

℞.—Pilocarpin. muriat. . . . . gr. iss
Aquæ dest. . . . . f℥iiss.

The patient at once began to perspire abundantly, and for six hours was continuously bathed in perspiration; at the same time abundant salivary discharge was excited, amounting the first day after the injection to fully a quart.

The only unfavorable symptoms noted subsequent to the administration of the drug, were repeated vomiting and difficulty in swallowing. Brandy in quantities of a teaspoonful was administered two or three times hourly, and no symptoms of collapse were manifested. The second day a half syringeful of the same solution was injected, the third day two-thirds, and the fourth day a whole syringeful, and for three weeks subsequently a like quantity was injected into each thigh alternately.

The quantity of urine increased under the treatment from eleven ounces per diem, having a specific gravity of 1040 at the time of the first injection, to more than two quarts, with a specific gravity of 1002 at the twentieth injection. With the twentieth injection the dropsy had entirely disappeared, and the extreme emaciation of the patient became apparent. In the region of both trochanters, on the outer side of each thigh, as well as upon the outer side of the legs, there were large purse-like expansions of the cutis, due to phlegmonous inflammation in the subcutaneous cellular tissue, fluctuating and painful on movement.

Believing that the small quantity of albumen still persisting in the urine, and the feverish condition of the patient, were a result of these purulent collections, Dr. Lazarus opened the pouches at brief intervals, and treated them antiseptically with iodoform gauze and drainage; they rapidly healed, as did also the bedsore and superficial gangrene of the scrotum. At the same time the secretion of urine rapidly increased, so that the quantity passed exceeded the normal, reaching three to four quarts daily. The cicatrization of the last suppurating cavity was followed by the entire disappearance of albumen from the urine. The patient was finally subjected to further treatment by hot baths, and daily increased in strength, his health finally becoming entirely restored.—*Wiener Med. Presse*, August 2, 1885.

CARCINOMA OF THE RECTUM.

IN the *Beilage zum Centralblatt für Chirurgie*, No. 24, 1885, DR. KRASKE, of Freiburg, describes an operation for the removal of carcinoma of the rectum, in which the growth is seated too high to be extirpated by the usual method, and too deep to be reached by laparotomy. The patient having been placed upon the right side, a median incision is carried from the second sacral vertebra to the anus; the left gluteus muscle is severed from its attachment to the sacrum; and, after excision of the coccyx, the tuberoso-sacral and spinoso-sacral ligaments are detached from the sacrum, when, by forcibly retracting the wound to the left, access to the upper portion of the rectum is greatly facilitated. The operation may be rendered still less difficult by severing, with the chisel, a portion of the corresponding lateral mass of the sacrum, the section being made in a concave line, which, beginning at the outer border of the third sacral foramen, curves downwards and inwards, traverses the fourth sacral foramen, and terminates at the cornu of the sacrum. Conducted in this way, the procedure spares the ventral branch of the third sacral nerve, and the sacral canal is not opened.

The operation, thus briefly described, has been performed by Kraske on two patients, both of whom recovered. Of the final results, however, we have no information, as the cases were evidently recorded shortly after recovery. Should the future show that the subjects were permanently relieved, the end surely justifies the means; but unless such a termination be reported, we think that surgeons will be slow to adopt the procedure, especially when they remember that carcinoma of the first portion of the rectum is usually firmly adherent to the sacrum, and that lymphatic involvement is present in not a few cases.

In rectal carcinoma which is beyond the reach of extirpation from the perineum, we take it that the interests of the sufferer will be best promoted by resorting to right or left lumbar colotomy, or establishing an artificial anus in the iliac region. Instead of performing an ordinary lumbar colotomy, the entire calibre of the gut may be divided, its central end attached to the external wound, and the peripheral end returned into the belly, after closure of its lumen. By adopting this suggestion, which originated with Madelung, of Rostock, there will be less disposition to prolapse of the gut, the mechanical, septic, and chemical irritation, to which the carcinoma is subjected by the retention and passage of the feces in the ordinary operation, is removed, and the annoyance, pain, and discomfort which result from the accumulation of feces between the tumor and the external sphincter are prevented.

That these advantages of Madelung's procedure are not imaginary is shown by a case recorded by SONNENBURG, in the *Berliner klinische Wochenschrift*, No. 35, 1885, but in which the operation was performed through the belly. In an example of carcinoma of the upper portion of the rectum, that surgeon attempted to extirpate the disease by a median laparotomy, but the adhesions were so firm and so numerous that removal was impracticable. The central end of the gut was, therefore, attached to the outer wound, and an artificial anus was established, through which the patient had a regular morning evacuation, the bowels remaining quiet during the intervals. There was an occasional discharge of a little mucus from the normal anus; there was entire freedom from pain; and the patient was gaining flesh at the date of the report.

In the same class of cases, Verneuil prefers to make an artificial anus in the iliac region. Instead, however, of practising the ordinary operation of Littre, he fixes the colon in the wound with about fifteen metallic sutures, and resects the anterior three-fourths of its wall, leaving the posterior fourth, with its mesocolic attachment, to form an éperon or spur, which prevents the passage of feces into the inferior portion of the gut. Although this operation, which is described in the *Semaine Médicale*, for April 1, 1885, is intended to meet the same indications as that of Madelung, we regard it as being inferior to the latter.

THE PUERPERAL FEVERS.

THE second volume of *Barnes's Obstetric Medicine and Surgery* has just appeared, and we turn with especial interest to that part devoted to what has been known as puerperal fever, but which recent ob-

Digitized by Google

stetric writers have generally called puerperal septicæmia. Here we find nearly one hundred pages given not to puerperal septicæmia, or to puerperal fever, but to "the puerperal fevers." For Dr. Barnes there apparently are four of these fevers, the classification resting, as it seems to us, not so much upon their clinical histories, as upon their asserted etiology. The general statement made by him is, that puerperal fevers are autogenetic, or heterogenetic. The autogenetic fevers are caused by endosepsis, of which there are two varieties, one arising from prolonged labor, nervous and muscular exertion causing a peculiar alteration of the blood, and the other from the non-elimination of effete material thrown into the blood by the involution which follows labor; or the fever may be caused by autosepsis, this term signifying absorption of putrid material which arises from necrosed or decomposed tissues of the mucous membrane of the genital canal, or from decomposing clot or fragment of placenta that has been retained. Hetero-infection is caused by infection or inoculation with some foreign poison: this is exosepsis. "Thus we may understand," says Dr. Barnes, "that there may be a simple endosepsis, that autosepsis is grafted upon endosepsis, and exosepsis is a compound of all three." We do not understand how exosepsis is a compound of all three, that is, of itself, of autosepsis, and endosepsis, especially, when a moment before it was stated that it was caused by "some foreign poison." However, the underlying fact in all is septicæmia.

The author proceeds to state:

"Thus we arrive at the demonstration of the fallacy so often uttered that scarlatina in a puerpera is scarlatina and nothing more. It is something more. It is the foreign zymosis grafted upon the puerperal condition, and modified by it. If the foreign zymosis do not find at the moment of its entry an existing autogenetic fever, this is instantly and necessarily produced." This statement is too absolute, as several published cases of the so-called puerperal scarlatina testify. Indeed, Dr. Barnes himself on a subsequent page contradicts it, saying, "so in some healthy puerperæ the scarlatinal poison runs a simple course, all the special phenomena appearing in due order."

According to Dr. Barnes, endosepsis produces a fever possessing little or no infective property; autosepsis and exosepsis are highly infective. Might not this statement be given another form? Mild cases of puerperal septicæmia are not as contagious as the grave ones. And, further, if autosepsis and exosepsis are highly infective, is it not rational to believe that their essential cause is one? Nay, take all the different varieties of sepsis, those with little, as well as those with great infective power, do they not point to unity of cause?

One thing we are especially glad to see in Dr. Barnes's exposition of the puerperal fevers, is that he denies the existence of simple traumatic fever, which is given such an important place by the German obstetric writers especially, among whom we may mention Kleinwächter.

In the course of the article in relation to etiology, Dr. Barnes says: "Everything is prepared for inflammation. The local injury, the hyperinotic blood charged with effete matter, are there; an exciting cause is alone wanting. A chill is sufficient." But is the chill of puerperal septicæmia cause or consequence? While it occurs in the great majority of cases, most authorities regard it as an indication that infection has already occurred, it is the first manifestation, not the cause of the fever: it is the cry of alarm, the signal of distress.

Several questions are suggested by Dr. Barnes's opinions as to the etiology of the puerperal fevers. For example, if protracted labor produces endosepsis, why do so many primiparæ escape? They have muscular and nervous exhaustion in most cases, yet it is altogether exceptional for them to have septicæmia; a common cause ought to produce its effect in the majority, instead of in a very small minority of cases. Again, may it not be that the necrosed tissue of the genital canal, or the decomposing clot, or placental fragment in the uterus furnishes merely the nidus in which the germ-poisons entering from the exterior are developed? Would it not be quite as rational, instead of having so many varieties of sepsis explaining the mild and grave cases of the disease, to hold that the susceptibility to the poison differs, in different subjects, or that the quantity and quality of the poison vary? No one doubts the unity of the scarlet fever poison, and yet how various its manifestations in different subjects and in different epidemics. In the one case there is variety in the individual constitution, and in the other in that of the poison, though it is continually the same.

It is probable that all varieties of puerperal septicæmia depend upon one cause: this opinion rests in part upon analogy, in part upon the clinical history of the disease, and in part upon experiments made upon animals. That this cause is a *contagium vivum* is also probable from the rapidity of development of the poison—life can only explain such rapid evolution and multiplication. The remarkable results obtained, both in the prophylaxis and in the cure of puerperal septicæmia, by the use of antiseptics—the most efficient germicides being the most useful—tend to confirm this conclusion. Finally, this view is in conformity with much that science has taught us in regard to several other diseases which have been proved to be caused by living germs.

Delore, in his *Traité Pratique de l'Art des Accouchements*, Paris, 1883, remarks that the primary cause of puerperal septicæmia is the introduction of

Digitized by Google

bacteria into the organism of the puerpera, and that he himself was the first to place this beyond doubt. He found bacteria in the lochia, in the uterine cavity, and in the peritoneal serosity of women attacked with puerperal fever. He inoculated rabbits with the diseased fluid, and they died of purulent fever.

Rather than accept Dr. Barnes's quadrilateral septicæmia, we would prefer adopting the creed of Siredey: "We do not believe in *autoinfection* of the puerpera. For us all alterations are due to hetero-infection, and the constancy of the uterine lesions, and of their primordial appearance, leads us to regard the genital wound as the exclusive seat of the inoculation."

BACTERIA IN THERAPEUTICS.

PROFESSOR CANTANI, of Naples, has taken advantage of the well-known antagonism of certain forms of bacteria to each other in cultures to make a novel experiment in therapeutics. After satisfying himself of the harmlessness of the bacterium termo when injected beneath the skin, or inhaled, or taken into the stomach of animals, he proceeded in a case of phthisis to attack the bacillus tuberculosis with this common and vigorous microörganism. The case was one with an extensive cavity in the left upper lobe, high fever, and copious expectoration, in which there were elastic fibres and numerous tubercle bacilli. Animals inoculated with the sputum became tuberculous. The case had resisted the ordinary methods of treatment, and was getting steadily worse. On the 4th of May inhalations of a spray of a pure culture of bacterium termo were begun, with the effect of rapidly reducing the amount of expectoration, and diminishing the number of the tubercle bacilli. The fever subsided, and the condition of the patient rapidly improved. On the 1st of June the tubercle bacilli could no longer be found in the expectoration, only the bacterium termo, and inoculation of the sputum in animals failed to produce tuberculosis. It is not to be supposed that the bacteria destroyed the deep-seated tubercle bacilli, but in recent cases of slight extent and superficially situated the method may prove of some service, though the difficulty of carrying out the details is a serious objection to it.

GONORRHŒA A GERM-DISEASE.

THE dependence of gonorrhœa upon specific germs is being more clearly shown, and is receiving more general professional acceptance. MARTINEAU asserts in the *Archives de Tocologie*, for September, that the gonococcus is absolutely characteristic of gonorrhœal inflammations, as all recent investigations demonstrate.

BUMM, of Wurzburg, has recently published a work upon the microörganism of gonorrhœal diseases of mucous membranes, an analysis of which is given in a recent number of the *Centralblatt für Gynäkologie*. He has given much time to the study of the subject, and the results of his observations and experiments are of great interest.

Bumm states that gonorrhœal bacteria, in contradistinction to all other forms, may enter the cell protoplasm, there reproduce, and form a round mass about the nucleus.

In all gonorrhœal inflammations gonococci can be found, provided no disinfectant treatment has been used previous to the examination. Secretions free from gonococci will not produce infection of a mucous membrane, while those containing even a minute number cause gonorrhœal inflammation.

Bumm succeeded in getting a pure culture of gonococci from a gonorrhœal conjunctival secretion, and inoculating the urethral mucous membrane of a woman with this culture caused typical gonorrhœal urethritis. He is disposed to reject most of the culture experiments made by others, but surely those of Paul, referred to by Martineau, and made known to the Société de Thérapeutique last October, were carefully made, and gave similar results to that of Bumm.

Martineau states, in his *Leçons Cliniques sur la Blennorrhagie chez la Femme*, that the micrococcus or gonococcus of gonorrhœa has been constantly found in gonorrhœal pus whether the disease affect the urethra, the vagina, the conjunctiva, the uterus, the vulva, the urethral or the periurethral follicles, or Bartholin's glands. "It is beyond doubt," he asserts, that "gonorrhœa is a venereal affection, virulent and contagious, *sui generis*, having its own individuality, and that it can only be reproduced by an infectious agent always the same."

THE PROFESSION IN CANADA.

FROM the admirable address of Dr. Osler, delivered at the meeting of the Canadian Medical Association at Chatham we gather some interesting details with reference to the state of the profession in the Dominion. In certain directions it appears to have made satisfactory progress, and to have reached a high degree of development.

The question as to who should rule, the profession or the medical schools, seems to have been settled at an early period, though not without a struggle. The Boards elected from the practitioners in each province have now full control over all matters relating to medical education and licensing, and the teaching bodies must conform to their requirements. The system is thoroughly democratic, and seems to meet the serious problem of the profession, viz., the unrestricted competition between the schools. It matters little if the requirements for the degree are easy, so long as those for the license to practise

Digitized by Google

are rigid. It is well known in Germany that the Staats-examen for admission to practise is more dreaded by the students than the examination for the Doctor's degree, though it bears the name *tentamen rigorosum*. For the Commonwealth to permit a profession to regulate its own affairs, and to say what the conditions of admission to it shall be, does not seem strange. The lawyers enjoy just such privileges. But we have to deal in this country with a profession jostled by a crowd of irregulars, who claim equal rights, and who have often a controlling influence in the Legislatures, so that the difficulties in the way of uniform legislation are almost insuperable. Dr. Osler does not mention that in the Province of Ontario the homœopaths have a certain number of representatives in the Board, and that homœopathic candidates, though conforming in all respects to the full requirements, are examined in therapeutics and medicine by special examiners We understand, however, that the effect of the strict regulations has been that, on an average, not more than one homœopath has annually presented himself at the Board. In the Province of Quebec, we believe, there is a special Homœopathic Board which, as candidates are so few, is rarely, if ever, called together.

That eleven schools of medicine are more than enough for a country like Canada, with a limited and scattered population, seems very evident, though the ratio to population is not so high as in the United States. The folly of so many schools becomes apparent when the financial basis is exposed. The true note is struck in urging the friends of higher medical education to assist in placing the schools in a position in which they will not be dependent entirely upon the fees of the students. Benefactions are coming at last in the direction of the medical colleges, and the example set by the citizens of Montreal in subscribing for an endowment of McGill Medical Faculty, and the munificent gift of Mr. Vanderbilt to the College of Physicians and Surgeons of New York, will not be without influence in other cities.

AN HISTORICAL INSTANCE OF ALLEGED LATE MENSTRUATION.

PROBABLY there is no more striking illustration of the truth that a man is incapable of judging alleged facts belonging to a department of knowledge which he has never studied, than was given by Gibbon in regard to the death of Asima, the mother of Abdallah. The statement referred to is found in a note to the fifty-sixth chapter of the *Decline and Fall of the Roman Empire*. Abdallah had for months successfully sustained the siege of Mecca, but was finally compelled to yield, the city was taken, and he was slain. The tidings of his death were borne to Asima, and Gibbon states as a "physical effect of her grief for his death, the return at the age of ninety, and fatal consequences of her *menses*." The authority from whom Gibbon seems to have derived this remarkable statement was D'Herbelot; and, upon referring to his great work, *Bibliothèque Orientale*, 1777, we find this author not only asserts the return of menstruation in Asima in consequence of the profound emotion caused by her son's death, but that the flow proved fatal in five days.

Now a knowledge of human physiology would have saved Gibbon from accepting as a fact so marked a violation of physiological law. Such a flow as occurred in Asima's case was in no proper sense to be set down as menstruation—the very fact of its proving fatal would be an obvious objection, apart from any other, to accepting such view.

If so learned a man as Gibbon, one so little disposed to be credulous that he often leaned to incredulity, could repeat that which every intelligent physician would reject, it is not astonishing that the ignorant will accept the most absurd statements in regard to medical matters, and are o frequently made the prey of designing quacks. The narrative too, has a wider application, as indicated at the beginning of the note.

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF VIRGINIA.

Sixteenth Annual Session, held at Alleghany Springs, Montgomery Co., Sept. 15, 16, and 17, 1885.

TUESDAY, SEPTEMBER 15TH.—FIRST DAY.

THE meeting was called to order at 8 P. M. by Dr. Bedford Brown, a railroad accident having prevented the President, Dr. S. K. Jackson, from arriving in time.

Dr. H. M. Clarkson, of Haymarket, delivered the annual address to the public and profession, taking for his subject, *Medical Societies: their Relations to the Public.*

DR. ISAAC WHITE, of Alleghany Springs, Resident Physician of the place, read a paper under the title of

MEDICINAL PROPERTIES OF ALLEGHANY SPRINGS WATERS.

The first portion of his paper referred to the geological formation of the framework of the Springs and surrounding country. The immediate vicinity consists (geologically) of magnesium, limestone, and argillaceous slates; while in the near neighborhood ore deposits are to be found—silver, iron, lead, and zinc. The temperature of the Springs stands about 56° Fahr.; the specific gravity at 1002.83; the taste of the water is saline, with an extremely faint but usually perceptible acid reaction. He gave the analysis, and stated that the effects of the baryta and strontia therein contained were in a measure similar to those of arsenic. He made this explanation because it was so common for him to be asked whether the Springs do not contain arsenic as a component part. He believed fully in the great value of Alleghany Springs water, but was by no means one of those enthusiasts who deem the one Springs they have faith in to

Digitized by Google

be a "cure all." Such claims being frequently put forth in relation to generally good Springs, often destroy belief that they are of any value whatever, in the minds of intelligent people. His great faith in the value of the water of these Springs was due to years of careful examination and experiment, and he felt that in certain forms of dyspepsia there is no natural water to be compared with it. The practical range of value of the water generally, beyond its special value just mentioned, is both great and extensive, and its uses should be made more widely known. The magnesian salts are undoubtedly a source of great power in these waters. When first drunk, a temporary, strange, giddy feeling in the head often occurs, soon followed by headache. He has seen erythema, eczema, and even boils, follow its use. The dose is a glassful, gradually increased to two teacupfuls before each meal, according as the intention is to get its tonic, diuretic, or cathartic effect.

DR. WM. C. DABNEY, of Charlottesville, as President, read the

REPORT OF THE STATE BOARD OF MEDICAL EXAMINERS,

showing that thirty-two candidates have passed satisfactory examinations since January 1, 1885, and have been licensed to practise in Virginia; six have been rejected. All of the candidates were college graduates.

WEDNESDAY, SEPTEMBER 16TH.—SECOND DAY.

MORNING SESSION.

THE PRESIDENT, DR. S. K. JACKSON, of Norfolk, delivered the

PRESIDENT'S ADDRESS.

He looked upon his elevation to the highest office in the gift of the Virginia profession as an expression of appreciation of his work to interest the Society in zymotic diseases, with special reference to prophylaxis. He first considered the hindrances to a rapid progress of the science of medicine; he then considered the most important factors in its recent high development; and, lastly, the most efficient agencies to invoke in order to secure its continued growth. The address was mostly of State interest.

The subject for general discussion,

SCARLET FEVER,

was opened by a full paper by DR. THOMAS J. MOORE, of Richmond. He adopted the usual divisions, such as scarlatina simplex, scarlatina anginosa, and scarlatina maligna. He gave graphic descriptions of each form, and traced the history of the disease from its earliest mention down to the present day. He discussed the origin of the fever, and laid much stress upon the germ theory. The success in cultivating and inoculating the special microbes of charbon, chicken cholera, murrain, and other diseases in the lower animals, with modification of symptoms and abatement in the severity of the respective diseases were described, and the hope expressed that corresponding advances in human *parasitology* may follow close in their wake. He stated that up to this time the only germ that has filled all the necessary requirements, as found in man through inoculation and otherwise, is the spiro bacterium of relapsing fever found by Obermeier, and called after him. The parallelism between smallpox and charbon was spoken of, travelling, however, in contrary directions; the one from man to the lower animals, the other from the domestic animals to man; the special bacillus of the latter had been discovered; through cultivation and inoculation it fulfilled all that the law required of it. Like vaccination in smallpox, it produced, through inoculation of a remote culture from the virus of one of the lower animals immunity in the human family. The peculiar microbe producing the former has not yet been determined. He hoped that it would come to light at a day not distant. Continuing, he stated there are two microbes described as giving origin to scarlatina, the monas scarlatinosum of Klebs, the plax scindens of Eklund, of Stockholm. Each is ingeniously and plausibly put forward as the true bacillus. Klebs does not indulge in the enthusiasm peculiar to confidence, while Eklund endeavors to demonstate the absolutism of his proposition.

Dr. Moore declared that he did not believe that the special microbe producing this disease had yet been recognized, and the question, to say the least of it, was undetermined and open. The part of the address in regard to treatment was long and exhaustive. He carefully discussed the merits of belladonna, cited the opinions of the homœopaths who had introduced it in this disease, as carrying out the very essence of their doctrine, with that of the regulars who had partially or completely accepted it. Dr. Moore does not think belladonna possesses prophylactic powers, and declared it to be an indifferent drug when used to mitigate symptoms during the progress of the disease. For the reduction of temperature he preferred the ice cap to the head, rubber bag over the front of the neck and covering the great vessels, conjoined with sponging. Failing in this, he uses the wet sheet, then the cold pack, and, as a last resort, the cold bath, as described by Ziemssen. He never fears the depressing effects of cold water, as patients can always be relieved from impending congestion by free resort to alcoholic stimulation. His favorite internal antipyretic up to this time was quinine, administered by rectum or hypodermatically, where the stomach was irritable. He hoped much from resorcin, and urged his brethren to try it, and give their clinical experience to the world; the drug is safe, certain in action, a germ destroyer. As an unguent, especially where itching and burning are prominent symptoms, he knows nothing equal to a combination of glycerine, borax, and carbolic acid, in the proportion of ℥, ʒ, and 15 gtt., respectively; both the borax and acid obtund nervous sensibility. He commended the use of unguents generally; they calm the patient and reduce temperature. He recommended sprays as the most efficacious manner of applying internal medication to the throat, and called especial attention to the value of hydrate of chloral, 2 to 4 grains to the ounce, as invaluable for its antiseptic and anodyne powers. This drug is likewise invaluable, he declared, in convulsions happening in children. It is best administered per rectum. Dr. Moore recommended the use of small doses of mercury for a few days as an adjuvant to diuresis in the dropsy attending acute desquamative nephritis, where diuretics were not accomplishing the desired end. Failing in these, a resort to hydragogue cathartics is indispensable. Jaborandi he had not tried in this fever; he feared its depressing effects; the physiological action of the drug is easy to induce, but diffi-

Digitized by Google

cult to leave off when desired. Nutritious food from the commencement of an attack, and free stimulation in all cases where the vital powers are depressed, he regarded as indispensable.

THE AFTERNOON SESSION

was devoted to the

ELECTION OF OFFICERS,

etc., with the following result:

President.—Dr. Rawley W. Martin, of Chatham.

Vice-Presidents.—Drs. John S. Apperson, of Town House; T. B. Greer, of Rocky Mount; and H. M. D. Martin, of Fredericksburg.

Recording Secretary.—Dr. Landon B. Edwards, of Richmond.

Corresponding Secretary.—Dr. John F. Winn, of Richmond.

Treasurer.—Dr. R. T. Styll, of Richmond.

Dr. Hugh T. Nelson to deliver address to public and profession, 1886.

Place of next meeting.—Fredericksburg.

EVENING SESSION.

DR. BEDFORD BROWN, of Alexandria, read a paper on

SCARLET FEVER,

in continuation of the morning's discussion. He has seen malignant cases with cold extremities and tongue, with a body temperature of 107°. He uses

℞.—Acid. salicylat. . . . . ʒij.
Tinct. aconit. radicis . . . gtt. xij.
Infus. digitalis . . . . ℥iss.
Spts. ammon. aromat. . . . ʒiij.
Syrup. aurant. cort. . . . ℥ss.
Aquæ . . . . . ʒj.—M.

S. Teaspoonful for a child five years old every three hours.

This combination reduces fever more decidedly than any other antipyretic he has used; it acts also as a diaphoretic and diuretic. A tepid bath or a wet pack increases its action. Alcoholic stimulants benefit malignant cases tending to collapse and coma, and also cases, on the other hand, having high fever, rapid pulse, and extreme restlessness. Such agents also generally arrest adenitis. In dangerous cases, frequent baths are too exhaustive. When extensive suppuration and pyæmia threaten, muriated tincture of iron, Fowler's solution, and quinia sulphate act well. To arrest acute nephritis and renal dropsy, envelop the body with a flaxseed meal poultice, covered with oil silk. When the kidneys are engorged, the urine bloody, with dropsy of the chest and abdomen, a full dose of calomel, followed by compound powder of jalap will often do good. Such cases bear purgation. But if the renal dropsy is attended with cool skin, great pallor, feeble pulse, and great prostration, then frequent purging is not well borne. In such cases, use lumbar poultices, digitalis, acetate of potash with occasional saline cathartics. A morbid element in scarlatina often develops rheumatism; hence the frequent cardiac complications. When these occur, resort to the active agents named in the above prescription. Alkalies and salines should be used for renal complications. Dr. Brown has been disappointed in the diaphoretic action of pilocarpin. Potassium iodide is often useful in nephritic sequelæ of scarlet fever.

DR. R. I. HICKS, of Casanova, has never seen anything indicating relationship between scarlet fever and diphtheria, nor has he seen scarlatinal sore throat threaten life. Mopping the throat, or gargling hot water will relieve the faucial troubles. He thinks the best treatment of scarlet fever consists in cold sponging the body, and the use of quinine and small doses of carbolate of iodine internally. Everything about the patient should be kept clean, and a current of fresh air should be kept up about the bed. Pull the bed out in the middle of the room—away from the corners—and keep the windows open. When the weather is very cold, use open fireplace rooms. Malignancy depends upon bad sanitation. Zymotic germs do not live in pure air. Filth breeds them. Soda salicylate irritates the stomach too much, and corrosive sublimate, in doses large enough to kill germs, will kill the patient.

DR. ALEX. HARRIS, of Jeffersonton, emphasized the benefit (1) of isolation, both to prevent and to cure scarlet fever; (2) sick-rooms with open fireplaces; (3) the bed should be out from any corner of the room, and draughts of fresh air should be made to keep the room ventilated; (4) the patient's and the bedclothing should be changed daily; (5) the popular disinfectants are not useful in permissible doses. Fire and water above 212° F. are the best germicides. Hence, burn or boil all clothing that has been about the patient; (6) always disinfect a house in which a zymotic disease has been treated, if even a year or two previously. Pour boiling water over the floors, in the cracks, on the wall, etc. Steam would be better.

DR. C. T. LEWIS, of Clifton Forge, believes in the stimulating plan of treatment, and thinks digitalis helps to relieve the swelling of the throat. Sometimes he uses chlorate of potash and muriated tincture of iron. He is a strong advocate of such sanitary measures as Drs. Hicks and Harris have just mentioned. He feeds liberally.

DR. JOHN F. WINN, of Richmond, agreed with the speakers as to their sanitary recommendations. He thinks, in towns especially, placards should be placed on doors of infected houses as warnings to visitors. Public funerals in all cases of death by zymotic disease should be prohibited by law. In the sick-room, use old cloths, etc., which may be burned up. The popular "disinfectant solution" of copperas is not a disinfectant, but is antiseptic. Four ounces of chloride of lime dissolved in a gallon of water is a good preparation to pour over the evacuations of typhoid patients. Corrosive sublimate in solution is also used. Let all articles that are to be used again be kept immersed in one or the other of these solutions for several hours. To disinfect a room, burn in it from two to four pounds of sulphur, and keep doors closed. If the body after death is to be removed, it should be kept wrapped in cloths wet with Labarraque's solution—℥iv to the gallon.

DR. L. LANKFORD, of Bowers, Va., agreed with the speakers as to the importance of fresh air in the treatment of scarlet fever, and thinks that malignancy would be rare if this were insisted on more than it is. As an illustration, he mentioned the cases of two of his children. The younger was kept downstairs in a warm

Digitized by Google

room with the doors closed, and malignancy developed; the other child was kept upstairs, where there was no fire and where a window was kept open, and no malignant sign or symptom developed. The weather was cold.

DR. J. HERBERT CLAIBORNE, of Petersburg, spoke of a case in his practice in which the dermic inflammation was so intense that, on the third day, the skin came off in large patches all over the body. Some children played day after day in the room with the patient, and yet none of them contracted the disease. Shortly afterward some other children had the fever so mildly that they could not be retained in the house; but in a short while, the disease developed in some of their playmates. An old lady living in the house with these mild cases had scarlet fever so severely that she came near dying. To disinfect a sick-room, not only the organic germs must be destroyed, but the spores also. A solution of corrosive sublimate (1:1000) is required to kill the spores, or water at 280°. But the best disinfectant for a sick-room after all is pure, fresh air. The doors and windows should be left open. Of course, always disinfect articles of clothing, etc. He thinks Squibb's solution of chlorinated soda—℥ij to the gallon of water—is the most efficient insecticide in the market, and it is cheap enough to be within reach of all.

DR. WM. L. ROBINSON, of Danville, believes a great deal of good results from proper medicinal treatment. He brings down the fever by using a full bath at 95°, which he allows to cool down to 85° while the patient is in it. Before taking him out of the bath, give a weak toddy and rub the body over with camphorated oil before he is put to bed. He depends very much upon the free use of lithia water as a drink. If the nose gets stopped up, so as to compel mouth bleeding, the child often wakes up from cat naps screaming. For this condition he uses a solution of two grains of chloral hydrate in an ounce of water with the steam atomizer. This keeps the nose moist. Large doses of calomel and jalap should be used if kidney complications threaten. In one case of œdema of the lungs, the hypodermatic use of pilocarpin cured the patient.

DR. W. W. PARKER, of Richmond, has often been disheartened at the results of treatment. Many cases get well without any special treatment, but until recently he did not get good results under any plan. Now, however, he has better results. The best remedy for malignant scarlet fever is alcohol in free doses. He keeps his patients hot. He got the suggestion from the good effects of alcohol in typhoid fever. Applications of turpentine are as good for the sore throat as carbolic acid. Keep the child in the house; in summer, about ten days; in winter, wait about three or four weeks.

DR. M. A. WILSON, of New River Depot, has used, with great satisfaction, Bartholow's tincture of belladonna prescription to antagonize that condition of the throat which causes exudation.

DR. HUGH T. NELSON, of Charlottesville, said patients often succumb to accumulations of heat around the nerve centres; hence the necessity for diaphoretics and heart stimulants. After these, use tonics.

Dr. S. K. Jackson, of Norfolk; Dr. Robert S. Lewis, of Culpepper; Dr. Wm. L. Broaddus, of Newtown; Dr. John Grammer, of Halifax Court House; and Dr. W. D. Cooper, of Morrisville, all spoke in the highest terms of praise of Watson's chlorine treatment, as described in his work on *Practice of Physic*.

DR. M. G. ELLZEY, of Washington, D. C., then presented his report on

CHEMISTRY, MATERIA MEDICA, AND THERAPEUTICS.

In reference to the advances made during the past year in materia medica and therapeutics, he thought all interest centred around antipyrin and cocaine—the two drugs most frequently mentioned by professional writers in the last twelve months. He thought the former had not realized the great hope induced at its introduction, namely, that we had a safe and reliable antipyretic. It had not only in frequent instances reduced the temperature of the sick body without changing in any manner the force of the fever illness, but its administration had at times been attended with alarming results to the patient. Its value had proved by no means as great as was at first announced, and its true place in our armamentarium can hardly yet be assigned. Cocaine has proved of wonderful power in some directions, but is not the general mucous anæsthetic that is claimed for it by a few enthusiasts. Dr. Ellzey is fully of the opinion that protective inoculation by attenuated choleraic virus is by no means operative. He shares the general opinion that the subject is one hardly worthy of discussion. He thinks Dr. Sternberg's researches are of more than ordinary value to the profession, and advised all physicians interested in the "germ theory" to follow up his studies. He advised more thorough study of the climatological peculiarities of Appalachian Virginia by the practitioners of the State. He thought that region a vast summer sanitarium.

DR. SMELT W. DICKINSON, of Marion, read the

REPORT ON ADVANCES IN OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN.

Antiseptic midwifery, he said, has undoubtedly saved many lives. But some of the antiseptic practices of a year ago have been done away with as being either useless or harmful—such, for instance, as routine vaginal and intrauterine injections after labor. Mercuric bichloride is dangerous in such injections; especially is it to be omitted when there is nephritis. Lying-in rooms should be aseptic, and whatever is to go into the vagina—such as hands, sponges, instruments—should be made scrupulously clean. Among other prophylactic methods, Cushing's was described. Thoroughly bathe the parts and then douche the vagina before delivery with weak solutions of corrosive sublimate, and after delivery of the placenta, wash out the uterus with a like solution. The doctor's and the nurse's hands should be kept aseptic all the time.

Post-partum drainage is readily effected by letting the patient sit upon the night-vessel when she wishes to urinate, etc., provided, of course, her condition otherwise permits it.

The contagium of puerperal fever must be of a material character, capable of being either destroyed or washed away by antiseptic injections. If body temperature rises materially above 100° after labor, with no other cause, and the discharges become offensive, use antiseptic washes at once. A doctor may return to his general practice after he has thoroughly used antiseptic washes and other precautions.

Digitized by Google

Extrauterine pregnancy is now treated by killing the fœtus by electricity and then by laparotomy.

Combined version in placenta prævia is done thus: Tampon the vagina until made sufficiently dilatable. Then anæsthetize the patient and remove the tampon. Introduce the hand and carry two fingers through the presenting placenta, and draw the fœtus to one side, while the other hand on the abdomen presses so as to carry the buttocks down until a foot can be reached. Draw the foot through the cervix so that the breech may act as a tampon on the lower segment of the uterus. Then wait for the spontaneous expulsion of the child, or for sufficient dilatability of the cervix to permit delivery.

Dr. Christopher Tompkins, of Richmond, in the treatment of the cord, recommends that it be drawn between the fingers until some of the gelatinous matter is expressed, and then tie as usual, except to apply a third ligature near the one left on the umbilical end of the cord. Credé and Weber prefer absorbent cotton as a dressing for the cord, to prevent umbilical inflammation.

Abortion is approved when dangerous conditions call for it. The lying-in room should have a regulated temperature. Swinging as a substitute for artificial respiration is urged by some.

Of diseases of women, neurasthenia is the most prominent. Nervous disease is often mistaken for uterine disease. According to Mitchell, neurasthenia is generally associated with anæmia, and is chiefly reflex in its manifestations. Rest, massage, electricity, and forced feeding are the essentials of treatment.

Lacerations of the cervix uteri will usually heal of themselves if blood poisoning is prevented. If operation should be required, relieve the cellulitis first.

Alexander's operation for backward uterine displacements consists in cutting down to the external inguinal ring, gathering up the ends of the round ligaments, and drawing them sufficiently out to replace the womb to its proper position. Then stitch the ligaments to the edge of the ring and cut off about an inch of the end. Drawing too much on the ligament has caused death. Wear a suitable pessary for two months. Prolapse of both ovaries into Douglas's cul-de-sac, with consequent sterility, may be cured by this operation.

Dr. Goodell advises rapid dilatation of the cervix for dysmenorrhœa instead of incision, especially for organic dysmenorrhœa, and also for nervous dysmenorrhœa.

In diseases of children, the use of large doses of carbonate of ammonia for scarlet fever is gaining favor. Dr. R. D. Huffard, of Smythe Co., uses the carbonate later in the disease, when the capillary circulation is languid. Bismuth subnitrate is good for the sore tongue, which usually occurs about the fifth day, as it is, also, in cancrum oris. Trypsin is a solvent for diphtheritic membrane when used as a spray every fifteen minutes or so, if the patient's strength will allow. Avoid chlorate of potash in febrile affections where the blood is alkaline, as in diphtheria, nephritic diseases with scanty urine, uræmia, etc. Icterus neonatorum is said to be due to incomplete closure of the ductus venosus. Dr. Hartigan, of Washington, D. C., supports Sims's theory as to the cause of trismus nascentium being "an inward displacement of the occipital bone."

(To be concluded.)

AMERICAN GYNECOLOGICAL SOCIETY.

Tenth Annual Meeting held at Washington, September 22, 23, and 24, 1885.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, SEPTEMBER 22D.—FIRST DAY.
MORNING SESSION.

THE Society was called to order at 10 o'clock, in the Lecture Room of the Columbian University by the PRESIDENT, WILLIAM T. HOWARD, M.D., of Baltimore.

DR. SAMUEL C. BUSEY, of Washington, delivered the following

ADDRESS OF WELCOME.

Mr. President and Fellows: I offer you the greetings of fellowship and bid you welcome guests of the Washington Obstetrical and Gynecological Society. The acceptance of the invitation to hold your tenth annual meeting in this city, and your presence here to-day, confer a distinguished honor upon our young society, now just completing its third year of existence, and affords an opportunity for its members to meet and make the acquaintance of men who by their brilliant achievements in the sciences of obstetrics and gynecology have won world-wide reputations, and added lustre and renown to American medicine.

We extend to you the hospitalities of fraternity, and, by our presence at this opening session, attest our professional regard and obedience to parental precept and authority.

It is a special gratification to know that the youngest of your natural offspring will enjoy the honor of commemorative union on this tenth anniversary of a society which, in the past decade, has contributed so much to the advancement of obstetrics and gynecology, and to the cure and alleviation of the afflictions of women.

On the roster of Fellowship the names of Atlee, Buckingham, Peaslee, Sims, Trask, White, and Wallace are marked with the asterisk of death. Others have come to fill the places of the lamented dead, and the future gives promise of even greater progress and higher excellence in the aims of conscientious and scientific medicine.

Then, here, at the Nation's capital, on this auspicious occasion, in the unity of a common purpose, let us join with you in that faith and devotion to duty which have been crowned with such marvellous success and rich rewards. You must lead; we will follow. And, when you have completed the labors of the present meeting, and the new and renewed friendships shall be interrupted by your return to the scenes of your daily work, if our gratitude as pupils shall be the measure of your pleasure as instructors, your second advent will not await the expiration of another decade.

DR. BUSEY then read a paper on

THE NATURAL HYGIENE OF CHILDBEARING LIFE.

Precocious nubility is the congener of precocious puberty. The latter is popularized as the sign of the former as the complement of maturity, whereas, in fact, one is the symptom and the other supplies proof of immaturity. Conjointly they represent the premature evolution of a function in an organism unfitted for its fruition. It is a law of the animal kingdom that pre-

Digitized by Google

mature reproduction arrests the growth of the body and diminishes functional energy; so, likewise, in the vegetable kingdom, premature fruiting injures development and impairs future productiveness. It is not, however, necessary to appeal to analogies found among the lower order of animals and in vegetable life for proof of the detrimental effects of the too early use of the faculty of productivity. Nor does its premature establishment necessarily imply that precocious matrimony will determine its maturity. Puberty must precede and marriage should succeed nubility. The order of succession is fixed, but wedlock should conform to the law which prescribes the period of greatest fecundity with the least mortality and greatest survival of children as the fitting time.

Precocious matrimony is, then, the sequel of precocious puberty, and, if it entails harm, the root of the evil must find its radical in too early puberty. In this country, and in the higher walks of life, the ratio of precocious puberty is manifestly on the increase. Whether equally so among the middle and lower classes is not known. If there is a like increasing ratio among the same class in other countries, the cause or causes might be more easily ascertained. But in some countries the hindrance of an advanced age of majority and the requirement of parental assent restrain precocious matrimony; consequently the evil tendencies and effects of such increasing ratio are less prevalently diffused.

The complex phenomena of precocity refer to erethism of those nerve-centres which preside over the brain and reproductive faculties. The predominance acquired by these vital activities subordinates those of the ganglionic system, and impairs nutrition. Overuse and disuse of faculty and organ, if not equally potent, are commensurate causes of disturbance. Exaltation of the cerebral and generative capacities involve corresponding deterioration of formative energy. This sovereignty of special attributes is more often traceable to external and extraneous stimuli than to heredity and defect of organization. Heredity is undoubtedly a prevalent factor. As runs the legend, one generation accumulates a fortune, the second divides, and the third squanders it. So one generation inaugurates the artificial methods of premature culture, the second intensifies the refinement of intellectual possibilities and emotional display, and the third explodes in caricature extravagances. The young, highly organized, and vascular brain-structure is stimulated by over- and too constant work. Repose and rest are sacrificed to baneful amusement and harmful entertainment. Early to bed and early to rise is the law of natural life, now becoming obsolete. One or more of the special senses are strained to the utmost attainment of mature development. The emotional excesses are displayed as esthetic accomplishments. The passions and impulses are cultivated by indulgences. The whims and caprices are gratified either by acquiescence or evasive suggestion of reprehensible expedients. The body, stilted on elevated heels, is geared from foot to crown into unnatural posture and ungainly carriage. Vital capacity is limited to the expansion of closely fitting corsets, and the figure is made to conform to the style of fashionable dressing. All these and many other practices are diligently taught to crown the adoration of parents.

DR. CHADWICK, of Boston, said that he had made a few investigations in regard to the early appearance of menstruation with reference to women of various nationalities in this country. In the examination of over 4000 cases it was found that American women menstruated earlier than women of other nationalities examined. Furthermore, American women of American parentage begin to menstruate earlier than American women of foreign parentage. Scarcely enough observations, in reference to the menopause, have been made to justify absolute conclusions, but he found to his surprise that the period of the menopause is appearing later in American women than in the foreign-born women in this country. If this is corroborated, the conclusion would be that the childbearing period is greater in American women than in women of other countries. The fact that the childbearing period is increased both at the beginning and the end, we should take as an indication of added vigor. There is no question of the fact that the number of children to a family is diminishing, but this can be accounted for by social influences, and is common to all civilized communities.

DR. JOHN P. REYNOLDS, of Boston, agreed entirely with this statement, and he believed that in the community in which he lives the women of the upper and middle classes menstruate earlier than they did twenty-five years ago. He believed that this indicates an activity of function which will prolong it beyond the average period of gestation.

A point of interest is in reference to the diminution of sexual power. He questioned whether this is not more dependent on individuality than on sex. He thought it doubtful that women pass the period for the relation of marriage and of childbearing sooner than men pass the period of procreation. This is, however, a most perplexing and obscure question.

DR. HENRY J. GARRIGUES, of New York, then read a paper on

PUERPERAL DIPHTHERIA.

This is a disease not referred to in the majority of text-books. It is one of the forms of puerperal fever, or rather one of the different diseases included under that term. It is distinguished by the appearance of diphtheritic exudation somewhere in the genital tract of the puerperal woman. It is accompanied by well-marked general symptoms, imperils life, and calls for active treatment. The paper was based upon 27 cases treated in hospital practice, and two cases occurring in private practice.

The characteristic feature of the disease is the diphtheritic infiltration, which is usually of light pearl-gray color. Generally appearing in small spots and coalescing or extending by involving new areas, the exudation is firmly adherent to and embedded in the underlying tissue. It is most marked at the points where the canal becomes narrow. This may be explained by the more frequent occurrence of lacerations at this point. The posterior wall of the vagina is more commonly attacked than the anterior wall, which is probably due to the fact that it is bathed with the discharges from the uterus. The exudation may, however, appear on entirely healthy portions of mucous membrane, which have not been the seat of laceration. The surrounding parts are more or less swollen. The connective tissue of the pelvis is infiltrated with serous fluid and is sometimes the seat of ecchymoses. The skin is sometimes the seat of

Digitized by Google

a dusky erythema, consisting of minute spots, disappearing on pressure and not elevated. In one case petechiæ as large as hemp-seed existed. These were not affected by pressure. The same patient later developed erysipelas.

In five cases ending fatally, autopsies were made. The uterus was much enlarged, sometimes reaching almost to the umbilicus two weeks after labor.

The cervix may be torn, showing diphtheritic patches or a thin gray film. In two cases, large portions of the cervix sloughed and the vagina became gangrenous. The tissue of the uterus is friable and may be almost diffluent. The diphtheritic exudation may affect the Fallopian tubes. In some cases the muscular tissue of the uterus is scooped out as in dissecting typhus, of which he had described several cases. This occurred in four of the cases of puerperal diphtheria. In one case the mass thrown off was four inches long, two inches wide, and one inch thick. These masses have a pear-shape, their outer surface is of a gray color, the inner surface flesh color. They are perforated with a number of holes leading into uterine sinuses. Under the microscope these masses are shown to consist of smooth muscular fibre in a more or less advanced state of fatty degeneration. The connective tissue is increased. Lesions are also found in other organs and occasionally in the joints.

Difficult labors and a previous weakened condition of the patient predispose to the development of the condition. The real cause of the disease is, however, an infection from the outside. Dr. Garrigues had never been able to convince himself that the poison passes from one patient to another, but it seems to be in the air of the ward. When a ward had been fumigated with sulphurous acid there would not be a seriously sick patient for weeks. That the poison comes from the outside is also shown by the fact, that when the prophylactic treatment to which he would refer is employed, the disease does not develop.

The first symptom which shows a deviation from a normal course is usually the occurrence of fever, which mostly appears from two to four days after delivery. Sometimes there will be a chill or chilly feelings. The temperature rises gradually as a rule. It has ranged from 100.6° to 107°, the average being from 102° to 104°. Anorexia, vomiting, coated tongue, and diarrhœa indicate disturbance of the gastro-intestinal canal. The patient complains of pain in the epigastrium and one or both groins, sometimes extending into the legs. Examination shows the uterus larger than it should be and quite tender. Tenderness is often also found in the groins and some swelling may also be observed. The lochial discharge is often scanty and offensive, but in some cases it has been normal. In those cases in which there was expulsion of the tissues of the uterus, there has been a purulent discharge until expulsion has been accomplished. The diphtheritic patch commonly appears from three to seven days after delivery. It continues to spread for several days, and usually stops in from three to eight days after the beginning of treatment. In one case the diphtheritic patches also appeared on the tongue, indicating that the disease is identical with the ordinary form of diphtheria attacking the throat. The irritation of the nervous system is evidenced by headache, stupor, and delirium. There is alteration of the renal secretion, and sometimes there is painful micturition. Three patients had albuminuria. In two cases jaundice bore testimony to the perverted condition of the blood. The sweet breath and profuse sweats of septicæmia were observed twice. One patient developed painful arthritis of the elbow-joint. When once the diphtheritic process is arrested, the patients recover rapidly.

There is scarcely any difficulty in the diagnosis. When the injections of bichloride of mercury are employed, they cause a yellow discoloration of abraded surfaces. This is strictly limited to the abraded surface, and is unaccompanied with general symptoms. When the chloride of zinc is applied to the affected surface in the treatment of the disease, a slough is caused having the color of the deposit, and the physician is sometimes at a loss to determine whether or not the disease is spreading. The point is decided by noting where the application is made and by observing the edge of the deposit. The diphtheritic deposit has a scalloped outline, while the outline of the slough is smooth.

As to prognosis, five out of twenty-nine cases died, giving a mortality of 17.2 per cent. Another of the cases might have survived, for she lived thirty-two days and died from rupture of the uterus while an assistant was using an intrauterine injection. The post-mortem showed the walls of the uterus to be extremely thin. The duration of the cases ending in recovery is usually about two weeks. In those cases in which a portion of the uterus is scooped out, the organ is left in a weakened condition, which in future pregnancies may predispose to rupture of the uterus.

In the way of prophylaxis, it is recommended to limit the vaginal examinations during labor as much as possible. The finger or hand should not be introduced into the uterus unless absolutely necessary. The delivery should be so accomplished as to avoid as much as possible wounding of the genital canal. Instruments should be used with care. The most important element in the prophylaxis is the use of bichloride of mercury as an antiseptic. Everything coming in contact with the patient should be washed in the solution of corrosive sublimate, 1 : 2000. After this treatment was introduced only one case appeared in six months, and that was due to carelessness on the part of an attendant, who delivered the woman immediately after removing a macerated fœtus from another patient.

After the disease appears the treatment must be energetic. The only treatment that has given me satisfaction is that with chloride of zinc. The affected parts are touched with a solution consisting of equal parts of chloride of zinc and distilled water. This is rather painful and an anæsthetic may be used. A warm solution of corrosive sublimate, one to two thousand, is used for intrauterine injection where this is required, and subsequently a suppository of fifteen grains of iodoform is introduced. If this is done, the process need not be repeated more than once in the twenty-four hours. The vagina is to be touched every three hours. The parts should be examined every day, and if the process is not arrested, the chloride of zinc is to be repeated. If the disease is limited to the vagina and vulva, the intrauterine treatment is omitted. Extract of ergot is also given with the hope of causing contraction of the uterus. Morphia, quinia, and digitalis are used as indicated.

Digitized by Google

High temperature is combated with sponge bathing, salicylic acid, and, if necessary, the rubber coil and ice-water. Carbolic acid is also given, sometimes combined with the compound tincture of iodine. If the temperature is not very high, warm poultices are preferred to the ice-bag and coil. Where there is diarrhœa, warm poultices are also considered preferable.

Samples of the occlusion bandage to be used after labor were exhibited. They consisted of a pad of absorbent cotton wet with corrosive sublimate solution, over this a piece of oiled muslin or rubber cloth, and over all another piece of absorbent cotton and a piece of muslin or flannel, to attach it to the binder.

DR. W. T. LUSK, of New York, said that ten years ago he had one hundred and fifty cases of this affection under his care. Of this number twenty-eight died. The epidemic could be traced to a patient brought into the hospital after a long labor. She was suffering at the time from syphilitic ulcers of the vulva, which was excessively inflamed. He extracted the child with forceps and the inflamed perineum tore. Soon after this the diphtheritic deposit appeared, and the whole ward was infected. . The first cases were the result of transference from the patient, for the question of contagion was not recognized as it is now. After a time, great care was taken to avoid every possible source of contact, but the disease continued and could only be explained on the supposition that the air of the ward was filled with germs. In his first cases, the treatment consisted in the application of equal parts of the solution of the persulphate of iron and compound tincture of iodine. The disease usually began with a certain degree of mildness and gradually became more severe. Of the first twelve cases only two died, while in the second set of twelve cases only two recovered. In the progress of the epidemic, the entire system seemed to be affected, even before the advent of labor. Since the adoption of Dr. Garrigue's suggestion, with reference to the use of corrosive sublimate injections, he had not seen a case of puerperal diphtheria in the course of three and a half years. He had neither had a death from fever, nor any cases of fever, the old-fashioned milk fevers even being absent.

DR. H. P. C. WILSON, of Baltimore, had always been averse to using bandages of any kind after delivery, preferring to have the napkins placed under the patient so as not to obstruct the free flow of the discharge, and to use frequent washings of the vagina with antiseptic solutions.

DR. WM. L. RICHARDSON, of Boston, said that during 1882 and 1883, he spent most of his time in fighting this puerperal fever with ill-success, until the appearance of Dr. Garrigues's paper. After adopting the use of the pad and the corrosive sublimate solution for the hands of the attendants and nurses, the hospital has been almost entirely free from the disease. There has been no death since these measures were adopted, and there have been only one or two cases which caused anxiety. He agreed entirely with what the reader of the paper had said. In regard to the use of the corrosive sublimate injections he has found that even so weak a solution as one to five thousand will sometimes cause salivation. Where he meets with this, he uses iodoform, as has been suggested.

DR. JOHN BYRNE, of Brooklyn, inquired of Dr. Garrigues whether he had noticed any vaginal deformity following this affection? He had seen one case in which such deformity occurred. A lady, after her fifth confinement, was taken with tenderness, fever, and so on, and on the fourteenth day had a copious hemorrhage. On examination he found the entire posterior and outer surface of the vagina almost completely detached. Acetic acid was applied, and the bleeding checked. An examination after the healing of the parts had taken place showed the vagina much shortened and narrowed in its upper part, the cervix being obliterated. The anterior portion of the cervix was in contact with the recto-vaginal septum. He told the patient, in reply to her inquiry, that it was not likely that she would conceive. His prediction turned out to be false. In the following confinement she was in labor twenty-four hours before there was the slightest appearance of an opening through which a fœtus could escape. There was bulging of the presenting portion of the uterus, and into this he made an incision, and the child was delivered readily, the patient making a rapid recovery.

DR. GARRIGUES thought that the endorsement of Drs. Lusk and Richardson would be sufficient to induce others to try the occlusion pads. During the year preceding the introduction of the new method of treatment the mortality was nearly seven per cent. During the next, with the new method of treatment, the mortality was one and a half per cent. During the second year it was less than three-fourths of one per cent. In the institution in which these observations were made there are a number of disturbing elements, one of the most important being its connection with a large general hospital. In this new method of treatment the antiseptics are applied only to the outside in normal cases. Only in abnormal cases are vaginal and intra-uterine injections employed. In reply to the objection of Dr. Wilson, he would say that the pads used are absorbent. In hospital practice the pad is changed every four hours; in private practice, three times a day is sufficient. He has never had salivation from the use of corrosive chloride. The nearest he has come to it has been fetid breath and diarrhœa. He has only seen two of the cases subsequently to recovery when in labor. In one there were great shortening and narrowing, but during pregnancy there was softening, and the labor was quite easy. The second patient is pregnant, and the vagina appears to be in good condition. In reply to a question, he stated that the use of pads prevents all offensive odor.

DR. H. P. C. WILSON asked Dr. Garrigues this question: Suppose a case of lacerated perineum, not sufficient to need sutures, in which serre-fines were used, would not the use of the pads interfere with the use of the serre-fines?

DR. GARRIGUES, in reply, said he thought not; the pads could be so adjusted as not to interfere. But in any event, if it did, he would dispense with the serre-fines and use the sutures, in preference to dispensing with the pads.

AFTERNOON SESSION.

DR. JOSEPH TABER JOHNSON, of Washington, reported

FOUR CASES OF OÖPHORECTOMY, WITH REMARKS.

Case I.—Miss M., had suffered severely from chronic oöphoritis and menstrual epilepsy. She was at this

Digitized by Google

time 29 years of age, and had suffered for fourteen years. There was constant pain in both ovaries, but most of the suffering was on the left side. For two weeks in every month she was under the care of an attendant, her education had been neglected, and she was in an almost inhuman condition. She had been under the care of skilful physicians, and almost everything had been tried. Oöphorectomy was, therefore, decided upon, and performed August 17, 1882. Both ovaries and one Fallopian tube were removed. For several months she had no periods and no spasms. Gradually her menses returned, and with them the convulsions in milder form. She is now menstruating with more regularity than before the operation.

Case II.—Miss W., aged 21, from being in affluence had been reduced to the necessity of earning her own living. Five years before coming under observation she took a severe cold at the monthly period. Since then she has suffered from chronic ovaritis. She also had leucorrhœa and a displaced uterus, for which she was treated without material benefit. He treated her for three months without benefit, and then removed the ovaries. She made a rapid recovery, and has since been free from pain.

Case III.—Miss S., aged 24, had been a great sufferer from dysmenorrhœa and reflex symptoms. She suffered with burning pain in the abdomen and head for ten days preceding menstruation. For several months there had been no flow, but the distressing symptoms continued. Both ovaries and tubes were removed. She made a rapid recovery, and continues healthy.

Case IV.—Mrs. —, aged 40, the mother of three children, had suffered with pain in the left ovary for twenty years. She had a lacerated cervix and perineum, which had been restored without improving the other symptoms. She had been under treatment for ten years, but was practically bedridden for three weeks out of every month. She wished to have the ovaries removed, but he advised her to wait five years longer, until the menopause would accomplish the same result. She, however, insisted on the operation, and he performed it last February. She did well for three days, when vomiting set in, and she died exhausted on the sixth day.

He then referred to the great importance of an early diagnosis in such cases in order that the operation might be performed before numerous adhesions had taken place and before the general condition had become so depressed, referring to the statistics of various operations in confirmation of his statements. He thought that many cases which are now lost from prolonged operations necessitated on account of the numerous adhesions, might be saved if there were means by which an early diagnosis could be made.

DR. R. S. SUTTON, of Pittsburg, said that we all admit that a woman with a cystic tumor of the ovary is doomed to death if the tumor is not removed; but when she is suffering from some disease of the ovary which does not give tangible evidence of its presence, the surgeon has often difficulty in deciding the question of operation. It may be that under ether and with bimanual palpation it is utterly impossible to detect any evidence of disease of the ovaries or tubes and yet the ovaries may be at the bottom of the trouble. Is the woman to be allowed to go on suffering because we cannot obtain evidence of disease that will justify an operation? It is better to give the woman the benefit of the doubt and open the abdomen and examine the organs. He did not believe that any one can tell the exact condition of the ovaries before opening the abdomen. It has now come to be the practice in obscure conditions in women for which no explanation can be found and in which it is probable that the ovaries or tubes are at fault, to make an exploratory operation. As a rule, exploratory operations are safe. He has yet to open the first abdomen and fail to find disease of the ovaries or tubes.

He removed both ovaries from a woman sent to him for operation for a lacerated cervix. There were symptoms which he could not refer to the condition of the cervix. On careful examination he found evidence of disease of the ovaries. He removed both ovaries. One contained a dermoid cyst, and the other had undergone cystic degeneration.

DR. W. H. BAKER, of Boston, said that this operation opens up a large field of usefulness to the gynecologist and of benefit to woman, but there is great danger of the pendulum swinging too far, and the operation be performed too frequently. He would not discourage the operation in properly selected cases. An operation which gives such brilliant results in properly selected cases is almost certain to be carried too far. The greater skill is shown in curing these patients without the removal of organs. We shall come to a better understanding as to when the operation should be performed, and when not, by studying the organ itself very carefully in those cases in which it has been removed. In all descriptions of the operation there should be an accompanying report of the microscopical examination.

The question of early diagnosis has been referred to, and this is a matter of the greatest importance. The ovaries and tubes are not the easiest organs to examine. Even where the ovaries are adherent to surrounding tissues, it is often extremely difficult to ascertain this fact, and exploratory operation may be the only way to determine the condition. Where exploratory incision has been made, and the organs found healthy so far as their gross appearance is concerned, he said that they should be put back and the abdomen closed, even if the woman suffers excruciating pain with the menstruation. He believed, if the same perseverance and good judgment were manifested in these cases as in others, we should be able to cure many of them without operation.

He could not agree with the author of the paper in regard to the increased danger from the presence of adhesions. The only death that he has had was in a case where there were no adhesions and the operation was performed with ease. In many of the other cases there have been extensive adhesions.

DR. THOMAS ADDIS EMMET, of New York, remarked that what he had to say was rather in the form of a protest. He is not an advocate of the operation and he thinks that more harm than good has been done by its performance. There are cases where the operation must be done. Where there is salpingitis with the tubes filled with pus the operation is certainly indicated. That the operation should be done, as it frequently is, for the relief of so many symptoms is, he thinks, a reproach on the profession. He can not advocate the opening

Digitized by Google

of the abdomen for the purpose of making a diagnosis. If the diagnosis can not be made before hand, he does not think it justifiable to run the risk of opening the abdomen.

For three years he has been looking for cases in which he considered the operation indicated, and he has seen but two such cases. One was a typical case in which there had been several attacks of peritonitis, following gonorrhœa. He found both tubes as large as his wrist and presenting the twisted appearance described by Tait. The history indicated the existence of pus. He urged an operation, but the patient refused. She was seen by Dr. Thomas who also recommended operation. She insisted upon staying in Dr. Emmet's private hospital. For five months there was no improvement. The treatment consisted of hot water injections, keeping the bowels regular, applications of iodine daily, and attention to the general health. After several months, the tubes began to diminish in size, and in the course of a year the accumulation entirely disappeared and she left the hospital apparently a well woman.

The second case was similar; she also refused an operation. She is now no worse, and in some respects better than she was some years ago.

DR. LUSK said that great caution must be exercised in the performance of this operation. He recently saw a lady who had pelvic inflammation following the use of a stem pessary. There is now thickening of the broad ligaments. She visited a gynecologist, who advised the removal of the two ovaries. He could find no evidence of disease of the ovaries or tubes. In many of the operations which he has seen there has been no evidence of disease in the ovaries or tubes removed. He does not condemn the operation. He has operated in four cases in which there was distinct evidence of disease of the tube, with good success.

DR. H. P. C. WILSON thought that many cases have been operated on which should have been left alone; but there are many cases which nothing but the operation will relieve.

DR. E. W. JENKS, of Detroit, was aware of several cases in which the operation has been performed without benefit. Where the ovaries and tubes are diseased, there can be no question as to the propriety of its performance.

In many of these cases of so-called hystero-epilepsy, which are often nothing more than hysteria, he considers the removal of the ovaries and the stopping of the prospect of the patient becoming a mother, a positive wrong. The exploratory operation is not free from danger, as he knows of four deaths under these circumstances, in which no disease of the ovary was found.

DR. T. A. REAMY, of Cincinnati, said that one woman was sent to him with dysmenorrhœa and hysterical symptoms, with the request that he should remove the ovaries. It was a well-marked case. Five month's treatment of the cavity of the uterus with change in her surroundings and general treatment, resulted in entire recovery. He had had several other striking cases.

It is the exception to find the ovary healthy in women after the age of forty. He has been making these observations for ten or twelve years.

DR. EMMET said that this operation is sometimes done for dysmenorrhœa. He thinks that it should never be done for this condition. He considers dysmenorrhœa a neuralgic condition, the result of anæmia. When the dysmenorrhœa is relieved by operation, it is because the general nutrition is improved by the removal of the ovaries.

DR. SUTTON agreed with Dr. Baker that where, in an exploratory operation, the ovaries and tubes are found to be healthy, they should not be disturbed.

DR. M. D. MANN, of Buffalo, said that Dr. Emmet has made the statement that dysmenorrhœa is a neuralgic condition, and is not an indication for the operation. Although it may be neuralgic, he thought that the neuralgic condition may become so firmly established that it cannot be relieved without taking out the seat of the neuralgia. In two such cases he had thought the operation indicated. In one the patient was free from pain only three days in each month. He advised the operation, which was performed by Dr. Clark, of Niagara. The patient completely recovered.

The second case was his own. The woman had suffered for a number of years with excruciating pain. The ovaries were enlarged and tender. The whole abdomen was tender. The ovaries were removed and the patient entirely recovered her health. He cannot admit that there are no cases of ovarian dysmenorrhœa which can be relieved by the operation. He, however, thinks that they are rare.

DR. J. TABER JOHNSON did not recommend the operation except under well-marked indications. He agreed with those who fear that the operation may be performed oftener than necessary. Its use in nervous and neuralgic conditions is not always as beneficial as in some other conditions, myoma of the uterus, for example.

(*To be continued.*)

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, September 3, 1885.

(Concluded from page 331.)

THE PRESIDENT, B. F. BAER, M.D., IN THE CHAIR.

DR. E. E. MONTGOMERY read the following supplement to his paper on

BROMIDE OF ETHYL.

I read a paper on bromide of ethyl as an anæsthetic in labor before the April meeting of this Society. Although I did not attempt a history of the early administration of the drug, subsequent investigation has shown me that I did Dr. L. Turnbull injustice in not mentioning that to him we are indebted for the revival of this agent and its first use in this country. In following the German literature, by which I was led to use this drug in labor, I ascribed its first obstetrical use to Lebert, of Paris. The first case in which he used it was for the application of forceps, and occurred in March, 1881; but a paper, published by Dr. Turnbull (*Medical Bulletin*, June, 1880) shows that he had then used it in a second case of labor, and spoke in high terms of its peculiar advantages. Dr. H. Augustus Wilson had used it in labor prior to August 7, 1850, when he published an article upon this drug (*Medical and Surgical Reporter*, August 7, 1880). It becomes quite evident that the first obstetrical trial of this agent was made in this city, and the priority lies between the gentlemen named. Various mixtures of the ethyl have been ad-

Digitized by Google

vocated in labor and minor surgical operations. Booth, of Ohio (*Therapeutic Gazette*, 1884-85), recommends alcohol two parts, chloroform and bromide of ethyl, each one part.

Dr. W. H. Byrd, of Quincy, Ill. (*Ther. Gaz.*, March, 1884), has used bromide of ethyl one part, chlorofrom three parts, alcohol four parts, in some ninety-eight cases, without a single unpleasant symptom. It has not everywhere received the same condemnation that is shown by the hesitancy to use it in this city. In spite of the bad name given it by two deaths under its use, and the apparently dangerous symptoms induced by experiments upon the lower animals, its use has been revived by Chisolm (*Maryland Med. Journ.*, 1882-3, ix. 388), and Prince (*St. Louis Med. and Surg. Journ.*, 1883, xiv. 297), who strongly urge its use in minor operations and preliminary to the administration of ether. The last named has reported five hundred cases in which it was used without a single unpleasant symptom.

A leading article in the *Therapeutic Gazette*, June, 1885, advocates a redistillation of a mixture of bromide of ethyl and olive oil as a valuable and safe anæsthetic in labor. These facts are referred to simply to induce the profession to give this anæsthetic a fair trial in ameliorating the terrible suffering of natural labor.

DR. MONTGOMERY exhibited a

UTERINE FIBROID POLYPUS.

Miss R., æt. 38 years, began to menstruate at 17 years. The flow was regular, quite free, lasting a week, and was attended with pain the first three days. Ten years ago she had a hemorrhage, and subsequently several such attacks. Two years later she had a severe hemorrhage, followed by a bloody discharge, continuing several months, since which time she has never been regular. The flow would occur frequently, be very profuse, and attended with pain and loss of flesh. The symptoms were more marked during the last year. At one of the hospital clinics, some years ago, the difficulty was ascribed to anteversion of the womb. Dr. Bourneville examined her three weeks ago, diagnosticated the condition fibroid polypus, and referred the case to me for treatment. She was quite pale, lips bloodless, complained of pelvic pain, and of a constant bloody discharge, which amounted to hemorrhage upon the slightest exertion. The vagina was dilated by a tumor the size of an orange, about whose pedicle could be felt the neck of the uterus. The finger passed into the os and about the tumor without difficulty. Every examination was followed by severe hemorrhage. The pedicle was cut through by means of the wire écraseur, and the tumor removed by means of polypus forceps.

Considerable hemorrhage followed its removal. As this was not controlled by applications of hot water, a tampon saturated with a solution of subsulphate of iron was introduced. This was removed on the second day. On the fourth her temperature was up to 103° F. She had a chill, and pains in various parts of her body. These symptoms vanished under the use of quinine, digitalis, and opium. Five weeks after the operation she appeared much improved; has had no bleeding since; her appetite and strength are greatly increased; the uterus is normal in size; the cervix still dilatable, and will admit the finger with pressure; the cervical membrane was in good condition.

The tumor was the size of an orange; the mucous membrane of the lower surface was ulcerated, so that vessels were ruptured, allowing hemorrhage on any exertion.

The case is of interest from the long continuance of the hemorrhage, and illustrates the importance of early and careful examination of the cavity of the uterus in cases of protracted hemorrhage.

DR. GOODELL seldom uses the wire now for the removal of uterine polypi. He prefers traction with twisting or enucleation by the finger. There is less bleeding, and he is afraid of "cupping" of the fundus uteri and its injury by being included in the wire loop. He had made traction with the obstetric forceps, and enucleated tumors so large as to rupture the perineum even after lateral incisions had been made in the labia. He has partially inverted the womb, enucleated the tumor, and then restored the organ to its proper form. The tumor sometimes occludes the os, and fetid pus from necrosis of the growth is imprisoned above it, giving rise to a suspicion of cancer.

DR. BAER thought Monsel's solution may have caused the high temperature. Vinegar would have been a better hemostatic, and it is also an antiseptic. From the appearance of the specimen a portion of the adventitious growth seems to have been left behind, and it would be interesting to know the history of the stump.

DR. PARISH has removed many fibroids of various sizes, and sometimes with degenerated tissues and fetid odors. The rapid recovery of Dr. Montgomery's patient was remarkable. It is much to be regretted when any portion of the tumor is left, since necrotic change is rapid and decided in such tissue, and there is danger of blood-poisoning. The pedicle, however, generally shrinks and disappears.

DR. GOODELL remarked that this tumor appeared to be sessile, and had been wholly removed. The pedicle proper is usually simply mucous membrane without adventitious tissue, and it makes very little difference if some of it is left behind, as it shrinks away and is absorbed.

DR. ALLEN sometimes regretted that he was compelled to leave a portion of pedicle or tumor in the uterus, but he has never seen any bad consequences follow it. He prefers vinegar to iron as a hemostatic, and considers it as good an antiseptic as carbolic acid.

DR. MONTGOMERY remarked that the wire evidently brought away all the tumor. There was no evidence of any remnant on examination to-day. In one case a portion of tumor or pedicle was unavoidably left, and he removed it some time afterwards by means of a tenaculum. He wounded his finger in doing so, and suffered from septicæmia. The woman had an attack of cellulitis.

Hopkins University, the Councillorship in the Section of Medical Education, Legislation, and Registration; Dr. Thomas T. Sabine, of New York, the Councillorship in the Section of Anatomy; Dr. Thomas M. Markoe, of New York, the Councillorship in the Section of Surgery; and Dr. E. G. Loring, of New York, the Councillorship in the Section of Ophthalmology.

THE CHESTER COUNTY (PA.) MEDICAL SOCIETY AND THE INTERNATIONAL MEDICAL CONGRESS.—At the stated meeting of the Chester County Medical Society, held September 8th, the following preamble and resolutions were adopted:

Whereas, The members of this Society feel a lively interest in the prosperity of the American Medical Association and in the highest success the Ninth International Medical Congress, and believe that when a mistake has been made, it is better to correct it, than to ignore it through a false pride of consistency; therefore,

Resolved, That it is the judgment of this Society that, while the American Medical Association has a perfect right to enforce its Code of Ethics upon all associations subordinate to it, it has no such right as regards the International Medical Congress, a body with which it has no fixed connection, and which does not undertake to regulate matters of professional ethics. That the attempt to organize the Congress solely from its own membership and that of subordinate associations was most unwise and inhospitable, and calculated to lessen the influence and usefulness of the American Medical Association.

Resolved, That we hereby instruct our delegates to the next annual meeting of the American Medical Association to use all honorable endeavors to secure that the false step taken at New Orleans shall be retracted; and that those who led the Association into the present folly shall not be entrusted with the arrangements for the International Medical Congress.

PUBLIC OPINION ON THE CONGRESS OUTLOOK.—It will thus be observed that the changes made by the Committee in the appointees of the Congress are not of a character to inspire the very highest order of scientific work, nor do we believe that the Congress, as now organized, will attract that attention and interest it would have received under the plan of organization first proposed. The revolutionary work of the American Medical Association, in authorizing the changes made by its Committee, is entitled to every atom of criticism and censure it has received. There was no reason or justice in its action. This action will have but one result, that of lowering the standard of scientific work in this country and of introducing into the ranks of the profession an element of discord and disturbance which cannot be effaced during the next generation. The Association has given its entire influence towards elevating the claims of men who care more for their own advancement than for the general professional good. It has favored an alliance with ideas and principles which have no existence in the scientific creed of our times. The present organization of the Congress, as far as it is known, bears no comparison in point of ability and authority to the first organization. Inasmuch as it has been called into existence out of deference to false issues and demagogical ideas, its results will not only prove highly prejudicial to the success of the Congress, but can have only an unfavorable influence upon the status of the profession in the United States.—*Maryland Medical Journal.*

For the first time in its history the International Medical Congress has fallen into the sole management of a society of the country in which it is to meet. Although Sir James Paget, an ex-President, expressly affirms that this was not expected or desired when an invitation was given, yet it is evident from recent events that the society referred to intends to retain its hold, and force upon the Congress its own men and methods. The work of the Committee which met here in such secrecy on September 3d but too surely confirms this. The details show some indications of adroit wriggling to escape the results of previous blunders, but no manly meeting of the issues, and no recognition of the real demands of the profession. The Committee have utterly eliminated and blotted out Drs. Cole and Shoemaker, trusting, we presume, to gain back Philadelphia by thus making scapegoats of these gentlemen. They have also filled the vacancies in the Presidencies of the Sections. Their list of names suggests both freshness and decay, but does not fairly represent American medicine. And the profession will very quickly ask who many of these new men are who thus take the seats which have heretofore been held only by recognized leaders. Is our country to be made ridiculous by their upheaval, and the Congress turned into a menagerie of unknown doctors and ethical sticklers?

However, though the appointments are weak enough, they need not kill the Congress. But a much more serious thing remains: no attempt was made to remove the Code issue from the Congress. It is still incumbent on an American physician to subscribe to the American Medical Association's Code of Ethics in order to hold any official position in the Ninth International Congress —if it meets in this country. The stupidity, as well as absolute wrongfulness, of failing to meet this point is certainly beyond parallel. The good Lord only knows, perhaps, what a number of nice, venerable, determined old gentlemen we have here trying to manage our little medical world; but many of us are getting some inkling of their immeasurable and fathomless fatuity. It appears, at any rate, that they are bound to destroy the Congress, for they persist in forcing upon it restrictions which cut off from the Congress and impugn the respectibility of a large number of the most honored men in our profession. In thus doing they violate justice and right, break the pledges at Copenhagen, and affront their fellow-physicians here. Of course a bitter controversy is inevitable; and we are sorrowfully forced to the conclusion that there is at present no hope for the Congress whatever. The profession here and in other centres is almost a unit against the policy of the Association and its Committee, and it will continue to protest against the organization of a meeting which will be so thoroughly misrepresentative of American medicine.—*The Medical Record.*

THE DISSENSIONS IN AMERICA.—Under this heading the *Medical Times*, of London, publishes a letter received from Dr. N. S. Davis, of Chicago, from which we make the following extract:

"As there is only one body in England representative

Digitized by Google

of the whole English or British profession, the British Medical Association, so there is only one in the United States which could, under any possible circumstances, represent the profession in the United States; and that is the American Medical Association. From Maine to California, and from the British possessions on the North to Mexico on the South, every State and Territory is represented in that body. Now, you say in your letter that you are 'sure that it was present to the mind of every one there (Copenhagen) that the invitation (to have the Congress meet in Washington in 1887) was one from the profession of America and not from any section of it, or any particular medical society in it.' To which it may be replied: The invitation was extended by Dr. Billings, and Dr. Billings had been appointed to extend the invitation. Who appointed him? Whence came his authority for assuring the Congress that it would receive a warm welcome in this country in 1887? He was one of a committee *appointed at* a meeting of the American Medical Association *by* the President of the Association, who acted *for* the Association, and by the authority of the Association. . . . . The American Medical Association has invited the Congress to meet in Washington in 1887, and the invitation has been accepted. The American Medical Association is fully competent to make all necessary arrangements for that meeting, on as liberal a basis as has characterized any of the preceding Congresses. We only ask that our brethren in Europe will reserve their comments until the programme is completed and before them."

The Editor of the *Medical Times* appends to this letter the following note:

"We have not space in the present number to deal fully with Dr. Davis's letter or with the other documents stating the case of the American Medical Association which have reached us. We may, however, point out here that the British Medical Association has never claimed to represent the whole English profession, though we believe its claim to do so, if it should ever be so ill-advised as to make it, would be much more valid than the claim put forward on behalf of the American Medical Association. Whatever Dr. Davis may say, the fact remains, as the officers of the London Congress have stated, that on no previous occasion has any medical body attempted to capture and run the International Congress as the American Association is now attempting to do."

A NAVAL MEDICAL EXAMINING BOARD is now in session at the Naval Hospital, Philadelphia, for the examination of candidates for admission into the Medical Corps of the Navy, in which there are 13 vacancies. Candidates must be between 21 and 26 years of age, and must apply to the Secretary of the Navy for permission to appear before the Board.

DR. WILLIAM GOODELL, of Philadelphia, was recently elected an honorary member of the British Gynecological Society.

RESIGNATION OF SURGEON-GENERAL HAMILTON.—Dr. J. B. Hamilton has tendered his resignation as Surgeon-General of the Marine-Hospital Service, to take effect November 1, but he remains in the service with the rank of surgeon. It is expected that he will be stationed at Chicago. Dr. Hamilton was promoted to the office of Surgeon-General in 1879.

SMALLPOX NOT ABATING IN CANADA.—There were twenty-seven deaths from smallpox in Montreal on the 21st.

A statement submitted at the civic Board of Health on the 22d inst., showed that of 184 deaths from smallpox for six days ending September 18, 169 were French Catholics, 9 other Catholics, and 6 Protestants. There were 50 deaths in the adjoining municipality in the last four days. The Gray nuns are taking charge of 186 patients in the city and 28 in Ste. Cunnegonde.

At the meeting of the Citizens' Committee, held on 22d inst., when the subject of compulsory vaccination came up, Alderman Gray, Chairman of the Health Committee, said that if they attempted to carry out compulsory vaccination in Quebec and the suburbs, the French people there would repel them by force.

SMALLPOX QUARANTINE.—The Governor of Massachusetts has requested the Secretary of the Treasury to appoint medical inspectors on the Canadian border, east of Lake Ontario, to inspect passengers arriving by rail through northern Vermont.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE FOUR WEEKS ENDING SEPTEMBER 19, 1885.

VANSANT, JOHN, *Surgeon.*—To proceed to New Orleans, La., September 16, 1885.

HUTTON, W. H. H., *Surgeon.*—When relieved, to proceed to Mobile, Ala., September 16, 1885.

LONG, W. H., *Surgeon.*—Granted leave of absence for ten days, September 1, 1885. When relieved, to proceed to Detroit, Mich., September 19, 1885.

FESSENDEN, C. S. D., *Surgeon.*—To proceed to Norfolk, Va., September 16, 1885.

SAWTELLE, H. W., *Surgeon.*—When relieved, to proceed to San Francisco, Cal., September 18, 1885.

GODFREY, John, *Surgeon.*—When relieved, to proceed to Louisville, Ky., September 16, 1885.

GOLDSBOROUGH, C. B., *Passed Assistant Surgeon.*—When relieved, to proceed to St. Louis, Mo.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING SEPTEMBER 19, 1885.

MURRAY, J. M., *Passed Assistant Surgeon.*—Resignation accepted to take effect January 1, 1886.

ROSS, J. W., *Surgeon.*—To special duty at New York.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 15 TO SEPTEMBER 21, 1885.

CAMPBELL, JOHN, *Colonel and Surgeon.*—Retired from active service, September 16, 1885.—*S. O. 212, A. G. O.*, September 16, 1885.

AINSWORTH, F. C., *Captain and Assistant Surgeon.*—From Department of Texas to New York City, for duty as Recorder of the Army Medical Examining Board.—*S. O. 214, A. G. O.*, September 18, 1885.

SHANNON, WM. C., *Captain and Assistant Surgeon.*—Granted leave of absence for four months, to take effect about October 1.—*S. O. 215, A. G. O.*, September 19, 1885.

ORIGINAL ARTICLES.

THE OCCURRENCE OF ALBUMEN, SUGAR, ACETONE, AND DIACETIC ACID IN THE URINE.

BY J. P. CROZER GRIFFITH, M.D.,
OF PHILADELPHIA.

ALTHOUGH so much has been written on the presence in the urine of albumen in its various forms, and of sugar; as also of certain other bodies whose nature has not been so well known; yet the method of recognition and clinical significance of some of these substances has been, at least in general, so little understood, that any lucid and systematic discussion of the subject cannot fail to be of advantage to the profession. This has been done very clearly in an address delivered by v. Jaksch before the Vienna medic. Doctor-Collegium, in December last, and still more elaborately in a recently published monograph by him on "Acetonuria and Diaceturia."

As Dr. v. Jaksch has requested me to present his views on this subject to the American profession, and encouraged by the fact that I have had the opportunity to study many of the cases on which he has made his observations, to note the reaction of the various tests employed in urinary analysis, and to hear the relation between the symptoms of the patient and the morbid elements in the urine frequently and fully discussed in the wards which he visits, I shall endeavor to give a brief résumé of the matter, so far, at least, as it bears upon the needs of the practising physician. In the examination of the urine for albumen, three tests can be advantageously used:

I. Boil the urine and then add a few drops of nitric acid. Any precipitate produced by boiling is formed either of phosphates or of albumen. If it becomes dissolved on the addition of the acid, it consists of phosphates; if not dissolved, it is albumen.

II. Filter the urine, and then add a nearly equal quantity of acetic acid. To this mixture add a few drops of a solution of ferrocyanide of potassium. A precipitate or cloudiness produced thereby consists of albumen.

III. Add to the urine a solution of caustic potash, and then a few drops of a solution of sulphate of copper. Albumen, if present, dissolves the precipitated oxide of copper, and produces a red-violet color.

As is well known, I. contains two possible sources of error, when but a small amount of albumen exists in the urine. 1st. If too much nitric acid be employed, the albumen becomes redissolved in the form of acid-albumen. 2d. If not enough of the reagent be added, all the basic phosphates may not be converted into soluble acid phosphates, and the albumen will then remain in solution as albuminate.

With II. there is only one possible disadvantage, *i. e.*, that if microörganisms in large numbers have developed, a clear filtrate cannot be obtained. It becomes necessary, in this case, to compare a specimen of the cloudy filtrate with another to which the reagents have been added. Any increase in cloudiness denotes the presence of albumen. But it is easy to prevent the formation of microörganisms by adding a few drops of a solution of carbolic acid to the urine while still fresh. The test is, too, so easy of employment, so extremely delicate, and so reliable, that it cannot be too highly recommended.

A mistake could arise, however, if we fail to observe whether the urine becomes at all cloudy on the addition of the acetic acid. Any cloudiness at this stage of the procedure indicates the presence of mucin or uric acid. It is easy, of course, to know whether albumen be present, by simply continuing the process, and noticing whether the cloudiness have increased.

These three tests, as already described, can be used in the following manner to determine the nature of the albuminous body in the urine.

If a precipitate is obtained with all three, or, especially, with I. and II., at least serum-albumen is present.

Propeptone is probably present when II. shows the existence of albumen, and I. forms a precipitate only after cooling; which precipitate, filtered and tested according to III., produces the red-violet color. Another test for propeptone is the following: Add to the urine a saturated salt solution, and then some drops of acetic acid. If propeptone be present, a precipitate is produced which disappears on the addition of an excess of acetic acid followed by warming, but which reappears when the solution again becomes cool.

If both I. and II. fail, but III. gives a positive result, there is peptone in the urine. But for the examination for peptone, this test is usually insufficient, and, when the urine contains serum-albumen also, the process, both for propeptone and peptone, becomes much more complicated. The procedures can be found fully described in the standard work of Neubauer and Vogel.

The significance of the presence of serum-albumen in the urine is a subject far too great for discussion here. The occurrence of propeptone, or of globulin, is of little clinical importance, so far, at least, as our present knowledge of them teaches us.

On the other hand, the discovery of peptone is often of the greatest diagnostic and prognostic value. Peptone in the urine is, as a rule, an indication of the formation somewhere in the body of pus, and the subsequent disintegration of the pus-cells. V. Jaksch mentions a case in which there were all the symptoms of deep-seated suppuration, yet no peptone could at any time be found in the urine. At the autopsy, a

Digitized by Google

widespread development of sarcomatous tumors was discovered.

Epidemic cerebro-spinal meningitis is accompanied by an extensive production of pus within the meninges of the brain and cord, and an excretion of peptone through the urine. Tubercular meningitis, on the contrary, has no pus, and, provided there are no centres of suppuration in the lungs or elsewhere, has no peptone in the urine. The diagnosis between the two disorders must sometimes be made purely on the presence or absence of peptonuria.

Regarding the examination of the urine for *sugar*, the physician certainly stands ready to welcome any method which is at once accurate, delicate, and invariably reliable. Trommer's test is the best we have had, and is very delicate. But it has been found that the same reaction can be produced by very many other substances, especially if the solution be boiled a considerable time. To be certain, then, from Trommer's test that sugar is actually present, the oxide of copper must be precipitated *before the fluid actually boils*. The test only succeeds, if this precaution is taken, when the urine is relatively rich in sugar.

The method of Emil Fischer seems to fulfil all the requirements. It is simple and delicate (showing one part of sugar in 100,000 of fluid), and up to the present time, at least, there has been no other substance than sugar found with which it will give the same reaction. The test depends upon the fact that grape sugar with phenylhydracin (C_6H_5,NH,NH_2) produces a substance called "phenylglucosazon," easily recognizable to the naked eye, and still more so under the microscope, as consisting of long, yellow, needle-shaped crystals.

The method of procedure is very simple. Mix fifty c.cm. urine and two grammes hydrochlorate of phenylhydracin with one and one half grammes acetate of soda dissolved in twenty c.cm. water. Warm gently (preferably over a water bath), and in ten or fifteen minutes, if sugar be present, the phenylglucosazon is precipitated, usually in crystalline form; sometimes amorphous. Even if the latter be the case, still some of the characteristic crystals can be found under a microscope of low power. Or the amorphous mass can be made to recrystallize out of alcohol. This method is exceedingly delicate, as already stated. I remember very distinctly a case of tumor of the cerebellum, in which the presence in the urine of sugar was made perfectly evident by Fisher's test, while that of Trommer gave no clear result. The procedure can of course be still further simplified by keeping the solution of acetate of soda ready for use, and by *measuring* the phenylhydracin after the first weighing to determine the volume.

The subject of acetonuria and diaceturia, which v. Jaksch has treated exhaustively in his monograph, deserves to receive more general attention. Of the various tests for acetone, the following (Legal's) is the one most easily carried out, and is reliable except where the urine contains but small quantities of the substance. A few crystals of sodium nitroprusside are shaken with water in a test-tube, thus preparing a fresh solution of the chemical. Some drops of this are added to the urine to be examined, and the mixture is then made distinctly alkaline by the addition of a solution of caustic potash. A red color is thereupon developed, whether or not acetone be present. This color rapidly fades; but if twenty or thirty drops of acetic acid be added, there appears after some seconds, in case acetone be present, following the course of the drops of acid, an intense, deep purple color.

But, as a rule, the quantity of acetone is too small to be detected in this manner, and it becomes necessary to isolate it by the distillation of the urine, previously slightly acidulated with sulphuric acid. This is a process too tedious and troublesome to be commonly employed.

In case, however, one wishes to distil, and then test the urine, the following methods especially recommend themselves:

1st. The iodoform test of Lieben—the most delicate—is as follows:

Add to the distilled urine a small quantity of potassium hydrate; then some drops of a solution of iodine and potassium iodide. If acetone, even in minute quantity, be present, a heavy yellow precipitate (iodoform) is *at once* produced. The only source of error in the use of this test is the possible presence of alcohol in the distillate, in which case, however, the formation of iodoform crystals takes place *but slowly*.

2d. Gunning employs, instead of the potassium hydrate and the solution of iodine and the iodide, ammonium hydrate and the tincture of iodine. Alcohol then causes no precipitate, while acetone produces one of iodoform, in addition to a black deposit of iodine which always falls although there may be no acetone. The precipitated iodine is soon redissolved in case the urine contains much acetone. If it contain but little, the iodoform crystals may be seen after 24 to 48 hours forming a thin layer resting upon the black precipitate of iodine.

3d. Reynolds's test: This depends on the solubility of mercuric oxide in acetone. A solution of caustic potash is added in excess to a solution of the bichloride of mercury, thus precipitating the oxide of mercury. This is mixed with the distillate to be examined, and the mixture then filtered. If acetone be present, a portion of the mercuric oxide has been dissolved by it before filtering, and can be detected in the filtrate by the ordinary reaction with sulphide of ammonium.

The method of Legal, previously described, is not so useful for the distilled as for the undistilled urine.

Diacetic acid has the peculiarity that it produces with a solution of the chloride of iron a Bordeaux-red color. Also that urine containing it yields very distinctly the various reactions for acetone. Yet the matter is not quite so simple as it would at first appear, inasmuch as there are a number of other substances which can produce the same, or a very similar coloration. Such, for example, are salts of formic and acetic acids; carbolic and salicylic acids, decomposition products of thallin, antipyrin and kairin, etc. To prove positively the existence of diacetic acid in urine, v. Jaksch advises the following procedure. To urine as fresh as possible are added a few drops of a solution of chloride of iron. If a

Digitized by Google

precipitation of phosphates takes place, it is removed by filtration, and the filtrate again tested. In case a Bordeaux-red color is produced, a portion of urine is boiled, and another portion acidulated with sulphuric acid, and shaken with ether. If the red coloration disappears on boiling the specimen of urine in which the test has already been made; if the reaction occurs but slightly, or not at all in the urine prepared by boiling; if after twenty-four hours the red color produced by testing the ether extract grows pale; and if, however, the reactions for acetone in the urine are very distinct; then we have to do with diacetic acid. V. Jaksch particularly emphasizes the fact, that, although urine containing diacetic acid gives so well the reactions for acetone, yet there is no acetone as such contained in it. Diacetic acid is, indeed, a substance which very readily resolves itself into acetone, alcohol, and carbonic dioxide.

The clinical significance of the presence of one of these two substances in the urine is very different from that of the other. Acetone accompanies cases whose course is, as a rule, favorable; at any rate, its appearance is no sign of ill-omen.

Diaceturia, on the other hand, is a most dangerous complication, and points to an approaching death in coma.

Acetone, in very minute quantities, is a constituent of normal urine. Pathological acetonuria, *i. e.*, where the acetone exceeds 0.01 gramme in the daily amount of urine excreted, accompanies all diseases with *high continued fever*, independently of what the nature of the disease may be. A diminution of temperature in any malady is accompanied by a corresponding lessening of the amount of acetone eliminated; and, on the other hand, if from any cause, whether a relapse or the development of some other disease, the temperature again rises,—acetonuria is again proportionately increased. Acetonuria often, although not necessarily, accompanies *diabetes*. There appears to be no relation whatever between glycosuria and acetonuria. The development of acetone in the urine of diabetic patients is sometimes accompanied by various unpleasant subjective symptoms, such as headache, loss of appetite, disorders of digestion, feeling of weakness, etc., which, however, last but a few hours. Apart from this, acetone in diabetes appears to have but little clinical significance, except that it may be the precursor of, and become substituted by, diacetic acid. In even the early stages of *carcinoma* acetonuria sometimes occurs, and, as in diabetes, is ushered in by subjective symptoms. V. Jaksch believes it probable that the cachectic condition develops sooner in such cases than in those not complicated by the presence of acetone.

Inanition, from whatever cause, is often accompanied by large amounts of acetone in the urine. Likewise, also, certain *psychoses*, accompanied by great mental excitement, or mania, exhibit at times very large quantities of acetone. Another class of cases, very interesting, but very rare, is that in which the acetonuria is a disease *sui generis*, and is the expression of an *autointoxication* with the substance (acetonæmia). I have had the opportunity of seeing two cases which must be assigned to this category. The first was that of a man brought into the hospital wildly delirious. His previous health had been excellent, and no cause could be assigned for his condition, unless, perhaps, a possible error in diet a day or two before. A physical examination revealed nothing amiss, except that there was in the urine an enormous amount of acetone. After a few days the acetone disappeared, and the man regained simultaneously his usual health.

The second was an exceedingly well-marked case of Addison's disease. The patient, after having been under observation many months, rapidly developed restlessness, excitement, delirium, and finally coma ending in death. In the meantime the urine had been found exceedingly rich in acetone. Diacetic acid never occurs in normal urine, and its presence in the case of adults is always a moment of the gravest import; whereas it rarely accompanies *high continued fever* in patients above the age of childhood; when it does appear it indicates that the malady will probably run a very malignant course. In acute febrile disorders in children, on the contrary, v. Jaksch has found diaceturia comparatively common, and the prognosis is not rendered unfavorable thereby. When accompanying fever, either in adults or children, it usually appears with the commencement of the disease, *i. e.*, it is not preceded by acetonuria, to which symptom, however, it frequently gives place as the fever diminishes. The well-known *diabetic diaceturia*, the precursor of diabetic coma, and often the successor to a long-continued acetonuria, is commonly observed in cases far advanced and much emaciated. It is usually ushered in by subjective symptoms, such as a feeling of weakness, depression, sometimes an inclination to sleep, and occasionally also by a tendency to coma, which either deepens or soon passes away, although the diaceturia continues. Indeed, diabetic patients suffering from diaceturia are liable at any time to develop coma and die. The nature of the diet, or the medicaments employed, appear to have no influence whatever on the presence or the degree of the diaceturia. As a rule, there is no relation between amount of sugar and that of diacetic acid eliminated. Sometimes, however, a sudden diminution of the glycosuria is followed by the appearance of a large quantity of diacetic acid, in which case coma rapidly develops, and death probably ensues.

Diaceturia, like acetonuria, sometimes appears in *mental diseases*, accompanied by conditions of great excitement, in *inanition* and in *carcinoma*. A *coma carcinomatosum*, similar to that of diabetes, and accompanied by diaceturia, has also been described. Death, however, with the symptoms of diabetic coma, can occur *without* the existence of either acetone or diacetic acid in the urine. V. Jaksch, therefore, proposes to do away with the name "coma diabeticum," and to apply to all those cases of coma, from whatever cause, which are accompanied by diaceturia, the name "coma diaceticum." There is also a diaceturia, the expression of an *autointoxication* from diacetic acid in the system, in which the symptoms appear without the existence of any other grave disease. In adults this is very dangerous, although fortunately of rare occurrence; beginning with vomiting, great

Digitized by Google

dyspnœa, and jactitation, it soon terminates in coma and death.

In the case of children it is a matter of much less moment, and occurs very much more frequently. V. Jaksch has repeatedly observed children in whom the signs of any other disease were wanting, but whose urine was enormously rich in diacetic acid. In such a case the child feels weak, has a thickly coated tongue, often slight conjunctival catarrh, sometimes vomiting, usually constipation, and very slight or no fever. In two or three days all the symptoms, together with the diaceturia, disappear. Other cases have more strongly developed nervous symptoms; and he believes that all these, as well as a portion of those described as "eclampsia infantum," must be attributed to an autointoxication with diacetic acid.

NOTE.—"Phenylhydracinchlorhydrat," which is, probably, not yet to be purchased in the United States, can be procured from C. A. F. Kahlbaum, Chemische Fabrik, Berlin, S. O., at the cost of six marks ($1.50) per 100 grammes.

DISINFECTANTS.

PRELIMINARY REPORT OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

XXI.

PRACTICAL EXPERIMENTS ON THE STERILIZATION OF FECES.

BY GEORGE M. STERNBERG, M.D.,
MAJOR AND SURGEON, U. S. ARMY.

IN the experimental researches heretofore recorded in this series of papers the germicidal value of various chemical reagents has been established by biological tests made with pure cultures of various microörganisms or with "broken-down" beef-tea. The latter test I consider the most difficult, as the putrid beef-tea, after having been exposed in the laboratory for several days, contains a variety of microörganisms, including several species of bacilli, especially *B. subtilis*, the spores of which have an extreme resistance. The results obtained in these experiments may, therefore, be safely used as a basis for determining the quantity of the chemical agents tested which will be necessary to sterilize *fluids* containing microörganisms, when these fluids can be fairly compared with the putrid beef solution used in our experiments—due allowance being made on the side of safety when practical recommendations are to be made. The liquid discharges from the bowels of patients with cholera, typhoid fever, advanced tuberculosis, septic diarrhœa, etc., may be fairly compared with our broken-down beef-tea, as regards physical and biological characters, and I should say, in general, that it would be within the limits of safety to prescribe twice the quantity of a given agent, for the disinfection of such material, that has been found necessary to sterilize the same amount of putrid beef stock.

But when we have to deal with formed or semisolid fecal matter the conditions are very different, and the data obtained in our experiments upon fluid material cannot be applied without making proper allowance for the larger amount of organic material associated with the germs which are to be destroyed, and for the fact that germs enclosed in masses of albuminous material may be protected from the action of the disinfecting agent. Especial care will be required in the practical use of the oxidizing disinfectants, such as potassium permanganate and the hypochlorites of lime and of soda. These agents owe their power to the fact that they are promptly decomposed by contact with organic matter, but this decomposition is entirely a chemical reaction, and only a given amount of organic material can be oxidized by a given quantity of the oxidizing agent; on the other hand, the disinfecting power of such agents is neutralized by a given quantity of organic material, whether this is in the form of living microörganisms, or of dead animal or vegetable matter. If, then, the organic material is in excess, germs embedded in it will escape destruction, and the only safe rule in the practical use of oxidizing disinfectants is to *use such a quantity of the disinfecting agent that it shall be in excess after the reaction has taken place.*

The following experiments have been made for the purpose of determining within the limits necessary for practical purposes the quantity of the disinfecting solutions heretofore recommended by the Committee on Disinfectants required to sterilize a given quantity of feces (normal).

Standard Solution No. 1.

August. 25.—Four ounces of semisolid feces added to *one pint* of standard solution No. 1, available chlorine 0.65 per cent. At the end of twenty-four hours no chlorine remained in the mixture, and two culture flasks inoculated with the material broke down—failure to sterilize.

28th.—Four ounces of semisolid feces added to *one quart* of standard solution No. 1, containing 0.85 per cent. of available chlorine. At the end of twenty-four hours a trace of chlorine (0.01 per cent.) remained; there was no appearance or odor of feces in the mixture—no cultures were made in this experiment.

31st.—Seven ounces of semisolid feces added to *two quarts* of standard solution No. 1, available chlorine 0.83 per cent. At the end of one hour there was a trace of chlorine in the mixture. Two culture-flasks inoculated remained sterile.

September 5.—Two and one-half ounces of semisolid feces added to *one quart* of standard solution No. 1, available chlorine 0.9 per cent. At the end of one hour the mixture was found to contain 0.1 per cent. of available chlorine. Two culture-flasks were inoculated at the end of one hour; both broke down after remaining twenty-four hours in the oven. As both flasks contained a pure culture of *B. subtilis* it was evident that this was the most resistant organism present in the material, and that all other organisms were destroyed,

7th.—Six and one-half ounces of semisolid feces added to *two quarts* of standard solution No. 1, containing 0.9 per cent. of available chlorine. At the end of three hours the available chlorine present

Digitized by Google

in the mixture was found to be 0.11 per cent., and at the end of twenty-four hours 0.1 per cent. Two tubes inoculated at the end of three hours remained sterile,

I conclude from these experiments that in practice it will be safe to use one quart of standard solution No. 1 for every two ounces of feces to be sterilized. Vallin estimates a complete (daily) evacuation of the bowels at from 150 to 200 grammes—say six to eight ounces. Let us keep on the safe side and allow one gallon of this solution, containing four ounces of chloride of lime of the best quality for the sterilization of a normal alvine evacuation. The daily cost *per capita*, for sterilizing feces would then be less than one cent, for chloride of lime can be bought by the quantity for three and a half cents per pound.[1]

Standard Solution No. 2.

August 30.—Two and one-half ounces of semisolid feces added to *one pint* of standard solution No. 2. The material was very completely deodorized by the potassium permanganate in the solution. A thorough admixture and breaking up of the fecal matter was effected in this and in the following experiments by stirring with a glass rod. Two culture-flasks were inoculated at the end of two hours; both remained sterile.

September 6.—Seven and one-half ounces of semisolid feces added to *one quart* of standard solution No. 2. There was a decided fecal odor at the end of twenty-four hours. Two culture-flasks inoculated at the end of twenty-four hours broke down with *B. termo.*

8th.—Seven ounces of semisolid feces added to *two quarts* of standard solution No. 2. Only a slight fecal odor at the end of twenty-four hours. A copper wire dipped into the mixture showed the presence of a salt of mercury in solution—deposit of metallic mercury on wire. Two culture-tubes inoculated in twenty-four hours remained sterile.

Making a liberal allowance on the side of safety, we may say that one gallon of this standard solution, containing two drachms each of mercuric chloride and potassium permanganate, may be relied upon for sterilization and deodorization of a normal alvine evacuation. The cost would be about two cents, if the materials were purchased by the quantity, and the solution made (without expense for transportation) as required.

The following experiments have been made with a solution containing four ounces of mercuric chloride and one pound of cupric sulphate to the gallon of water (standard concentrated solution). For use, this standard solution is diluted by adding eight fluid-ounces to the gallon of water.

August 29.—Eight ounces of semisolid feces added to *one quart* of above solution. Fecal odor not destroyed as well as by standard solution No. 2. Two culture-flasks inoculated at the end of twenty-four hours remained sterile.

September 2.—Three ounces of formed feces added to one quart of the above mentioned solution. Two culture-flasks inoculated at the end of twenty-four hours remained sterile.

[1] Price taken from the last number of the Druggist's Circular.

The following experiment has been made with solution of carbolic acid.

2d.—One and one-half ounces of formed feces added to *one quart* of a 5 per cent. solution of carbolic acid. Two culture-flasks inoculated at the end of twenty-four hours broke down with *B. subtilis, a pure culture*, showing that the spores of this bacillus had not been killed, but that the material had been sterilized so far as *B. termo*, and other putrefactive organisms present, were concerned.

A CASE OF DISLOCATION OF THE HUMERUS IN WHICH DUGAS'S POSTURE-TEST FAILED.

By WESLEY C. STICK, M.D.,
of Glenville, York County, Pa.

On February 24, 1885, I was called to see Mrs. B., aged about sixty-five years, who had been suffering all winter with a severe cough and a great deal of expectoration, and consequently was greatly emaciated and feeble.

She slipped on an icy walk and fell on her left shoulder, about eight hours before I saw her, from which she was suffering intensely. Upon examination I found a depression under the acromion process of the left scapula. The elbow was hanging from the side of the body and backwards.

The line of the axis of the shaft of the humerus was directed towards the clavicle, where I could easily feel the head of the humerus rotate whenever I rotated that bone. Finally, I applied Dugas's posture-test. She brought her arm tight against the walls of the chest, while her fingers touched the opposite shoulder; this, however, was very painful. I nevertheless was confident that I had to do with a forward dislocation of the shoulder-joint, and attempted to reduce the same as follows:

I tried the method with the heel in the axilla, but was not successful. I had her seated on a chair, my knee in the axilla, an assistant holding the right arm, while another grasped the left humerus above the elbow with one hand, and the forearm, flexed to a right angle, with the other. We now made traction backwards, gradually raising the arm to the level of the shoulder, then bringing it forwards. During this period with one hand I steadied the scapula, and with the other made pressure upon the head of the humerus in the direction of the glenoid cavity. The arm was now brought down, and the deformity had disappeared. Her pain was nearly all gone. She could perform the different movements of her arm with ease, and nearly without pain. She confined her arm in a sling for one week. Since then her arm is well.

I report this case for the purpose of showing that Dugas's posture-test is not infallible, as claimed by Dr. Frank H. Hamilton, or that bringing the arm and elbow against the side of the chest, while the fingers touch the opposite shoulder, is not a "mechanical impossibility" in dislocation of the shoulder-joint.

Her emaciation, and the flaccid condition of the tissues, I think, account for the failure of this *almost* "infallible" test.

September 3, 1885.

MEDICAL PROGRESS.

THE CURE OF PULMONARY GANGRENE BY THE INHALATION OF AIR IMPREGNATED WITH CARBOLIC ACID.—DR. CONSTANTINE PAUL, at the recent meeting of the Congress for the Advancement of Science, called attention to the efficacy of carbolic inhalations for the cure of pulmonary abscess.

Seven cases were reported in which the remedy was successfully applied, no failure being recorded. Dr. Paul, in considering the value of the proposed remedy, compares the results obtained with those secured by the inhalation of aromatics, etc., which are eliminated entirely through the pulmonary and bronchial apparatus. These, with the exception of eucalyptus, are pronounced valueless, because not possessing the power of checking putrefaction in the pulmonary tissue.

As a probable explanation of the method by which the carbolic acid acts in checking the putrefactive process, M. Paul refers to the results obtained by various bacteriologists, who have found this agent efficient in the destruction of bacteria.

In view of the fact that pulmonary gangrene is regarded by most authorities as almost constantly fatal, M. Paul considers the results obtained as noteworthy, and that the method is an acquisition to the therapeutics of the disease, and worthy of further trial. — *Gazette Médicale de Paris*, August 29, 1885.

DEATH DUE TO RUPTURE OF SUPPURATING BRONCHIAL GLANDS. — A somewhat uncommon cause of sudden death has recently been the subject of a coroner's inquest, and of some very unjust charges against the medical man in attendance. A little girl, aged 12, was taken to consult Mr. G. A. Tait, who found that respiration was difficult and prolonged, and that the child was feverish. Believing that he had to do with a case of ordinary laryngitis, he gave a dose of ipecacuanha, and, when summoned almost immediately afterwards to attend the child at home, he did not do so, supposing that the mother had been alarmed by the commencement of vomiting. Unfortunately, the child was suffering from tubercular disease of the bronchial glands; the glands had suppurated and broken down, finally opening into the trachea, and causing death in a very short time. Though a rare event, a certain number of cases of this kind are on record; in some a large piece of caseous material has become suddenly detached and impacted in the trachea, causing death in a few moments. The difficulty of diagnosis is exceedingly great, and has rarely been surmounted; the history is of great importance, but, in persons belonging to the class to which this little girl belonged, it is very difficult to obtain, and not very trustworthy. The condition is one which, both from the clinical and pathological point of view, would well repay further investigation.— *The British Medical Journal*, August 29, 1885.

OBSERVATIONS ON HEMIGLOSSITIS.—DR. PAUL GUETERBOCK, in a paper on hemiglossitis, gives the following résumé of his observations:

1. In several and indeed the most carefully observed cases of hemiglossitis, the extension of the pathological process was observed in the branches of the trigeminal nerve in the affected side of the tongue.

2. In several additional cases of hemiglossitis the participation of the chorda tympani in the disturbance, in addition to that of the right lingual branch of the trigeminal nerve, was at least very probable.

3. The unilateral affection of the tongue is never limited only to the territory of the glossopharyngeal nerve, but a sympathetic affection on the same side throughout the extent of the trigeminal nerve can, with certainty, be confirmed in cases of this order.

4. The influence of the hypoglossal nerve upon the development of hemiglossitis, up to the present time, cannot be demonstrated.

5. In like manner, the same may be said of the vasomotor nerves of the tongue, but their indirect influence in one-sided inflammation of the tongue cannot be denied.

6. In conclusion, the manner in which nervous derangement produces hemiglossitis is not discovered by direct examination, but from its analogy with herpes zoster in other regions of the body, it must be concluded that it is due to divers unfavorable influences, which the affected nerves experience either in their ganglia or in their course to the lingual mucous membrane, and also to wounds, inflammatory processes, and sympathy with pathological conditions of other portions of the nervous system—in a word, to any influence which can produce a unilateral increase of function in a nerve of the tongue.

From such unilateral increase of function may result modification of the affected tissue, and, in consequence of the latter, the introduction of infectious material from which may originate all forms of inflammation, ranging from the superficial formation of isolated vesicles to abscess and total gangrene of one-half of the tongue.—*Deutsche Zeitschrift für Chirurgie*, July, 1885.

THE PASSAGE OF PATHOGENIC MICROBES FROM THE MOTHER TO THE FŒTUS, AND THROUGH THE MILK.—M. KOUBASSOFF, by experimental investigations made on lower animals concerning the passage of pathogenic microbes from mother to fœtus, and through the milk, arrives at the following conclusions;

1. The bacilli of charbon, *rouget*, and tuberculosis inoculated on one female passed into the lacteal secretion.

2. Having once appeared in the milk, they remained until the end of lactation, or until the death of the animal.

3. The young fed with the milk containing the bacilli of rouget, charbon, or tuberculosis do not contract these diseases, and survive even when the mothers perish.

4. The passage of microbes from the mother to the fœtus depends, probably, upon the existence of direct communication between the bloodvessels of the mother and those of the fœtus.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, August 28, 1885.

THE BACILLI OF LEPROSY.—PAUL GUTTMANN, in a careful study of the bacilli of leprosy, observed in elevated nodosities in a girl twelve and a half years old, found the microbes always collected in cells, a feature which distinguishes them at once from the bacilli of tuberculosis, while the fact that they stain more easily than the latter further distinguishes them.

Digitized by Google

The bacilli are found especially in the skin, but also in other organs the seat of the disease, and even in the blood. As a rule, the organisms are extremely numerous at the seat of the lesions. Their microscopic appearances are the same in every case, and hence it is no longer doubtful that they are the cause of the leprosy, notwithstanding the failure of attempts to inoculate animals. These seem to be refractory to the disease, inasmuch as in no case has it ever been observed among them.—*Berliner klin. Wochenschrift*, 1885, No. 7.

THE PARTIAL REPRODUCTION OF THE TESTICLE.—PROF. LUIGI GRIFFINI, continuing upon frogs his experiments begun in 1882 upon dogs and cocks, concludes:

1. That in the frog, partial reproduction of the testicle occurs.

2. That the newly formed parenchyma is derived from preëxisting tissue.

3. That the plasmatic cells of the stroma take no part in the production of the new glandular parenchyma. —*Gazzetta degli Ospitali*, August 26, 1885.

THE ABSORBENT POWER OF THE SKIN.—M. C. KOPP, in the *Breslauer Artzl. Zeitschrift*, 1885, No. 6, considers the following propositions to be a résumé of facts found in reference to the absorbent power of the skin:

1. Pure water, or that containing dissolved matter, is not diffused through the intact epiderm.

Absorption is possible if the normal texture of the skin is destroyed, or if it be greatly macerated.

2. The same facts obtain in reference to alcohol and to alcoholic solutions.

3. There is slight absorption of atomized aqueous or alcoholic solutions, but in so slight a degree that it is of no practical importance.

4. Medicaments applied to the sound skin in the form of ointments, are not absorbed:

This is true of iodide of potassium, veratria, quinine, etc. On the contrary, salicylic acid in solution or in ointment is absorbed, because it possesses the power of rendering the epiderm permeable.

5. In the method of administering mercury by inunction, there is a mechanical penetration of exceedingly minute particles of the metal into the lacunæ of the epiderm, into the glands, and hair follicles. The theory of Voit as to the absorption of sublimated mercury is very probable.—*Gazette Hebdomadaire de Médecine et de Chirurgie*, August 28, 1885.

TEN THESES CONCERNING SPONDYLOLISTHESIS.—DR. LAMBL, on the data afforded by his investigations and studies during a period of thirty years, enunciates the following views as to the causation of spondylolisthesis.

1. For a correct understanding of the origin of spondylolisthesis, fœtal hydrorrhachis sacrolumbalis is not merely a plausible, but a necessary presumption.

2. Traces of hydrorrhachis are recognizable in all spondylolisthetic pelves, and hydrorrhachis is itself pathologically responsible for the deformity of the pelvis.

3. Attempt to deny the responsibility of hydrorrhachis in the production of the deformity, results in a two-fold evil: Excess of theoretical insufficiency, and defect of practical application.

4. Rejection of hydrorrhachis as a causal agent leads to the error of attributing the occurrence of spondylolisthesis to conditions with which it is entirely unrelated.

5. The expressions spondylo-schisis and spondylolysis, are not synonymous, and do not signify the same thing as olisthesis, and can neither be used interchangeably with one another, nor with "fractures" of the vertebræ, nor with attrition effects, similar to fractures, resulting from elongation and atrophy by pressure of the arch of the vertebra, without serious error of understanding.

6. The rudimentary cleft vertebra, which, thirty years ago was described and based upon two spondylolisthetic pelves, is of historical importance, even for the future, and nothing has been since brought forward to destroy its significance.

7. The so-called "retropression of the sacral basis," "hemiolisthesis," and "congenital olisthesis" were idle inventions, whose non-existence can be proven without special difficulty.

8. Fracture of the inter-articular portion of the fifth lumbar vertebra, and consequent olisthesis, up to the present time has not been recognized in a single case.

9. The explanation of the occurrence of spondyloptosis through a violent motion, or traumatic cause, rests upon a false basis, and insufficient knowledge of existing specimens.

10. The presumptive "fracture of the sacral articular process," as of etiological importance in the spondylolisthesis, is, mildly speaking, anatomical nonsense.—*Centralblatt für Gynäkologie*, June 6, 1885.

THE ABSORPTION AND ASSIMILATION OF ALIMENTARY SUBSTANCES.—HOFMEISTER, in the *Archiv für Experimental Pathologie*, 1885, Bd. xix. Hefte 1 und 2, by experimental investigation, has found:

1. That peptone does not exist in a free state in the circulation of the blood, but is found united with the cells.

2. In the adenoid tissue of the intestinal mucous membrane, notably in the Peyerian patches, abundant cellular proliferation occurs in well-nourished animals.

The number of cells in process of segmentation in the follicles and young cells of the efferent lymphatics is greater when alimentation is abundant.

3. As the lymphatic cells of the adenoid tissue are almost entirely composed of nuclear substance, it is necessary that the digested albumen be here transformed into this substance in order to be assimilated, and there thus takes place, in a very simple manner, the transformation of peptones and hemialbuminose into principles of the class of nucleines.

Hofmeister further concludes that the incessant formation of new lymphatic cellules constitutes the morphological expression of the chemical process of assimilation. —*Gazette Hebdomadaire de Médecine et de Chirurgie*, August 28, 1885.

A RARE CASE OF ENCYSTMENT OF A FOREIGN BODY IN THE IRIS.—E. BERGER, in the *Wiener Med. Blätter*, 1885, No. 6, reports the case of a peasant, in whose eye a small fragment of stone about one-twelfth of an inch in diameter was encysted, occupying a position in the iris about midway between the edge of the pupil and the corneo-scleral margin, and projecting into the anterior chamber of the eye. The fragment entered the

Digitized by Google

eye twenty-five years previously while the patient was preparing a millstone, and caused at the time slight pain, which disappeared in a few days.

Excepting slight loss of acuity of vision in the injured eye, no unfavorable results have occurred.

A few days since, for the first time, slight ciliary injection with pain in the eye, was noticed, but the patient refused to permit the extraction of the fragment.—*Centralblatt für die med. Wissenschaften*, August 15, 1885.

BENZOATE OF SODA IN THE SUMMER DIARRHŒA OF CHILDREN.—DR. GUOSTA believes the diarrhœa occurring in infants in hot weather to be a zymotic disease due to the presence of a special microbe produced by defective diet, bad hygiene and excessive heat being predisposing causes.

The remedy he prescribes for the condition is benzoate of soda uncombined with any other remedy, if the affection is recent, in children of from six months to two years.

After the administration of a purgative, such as calomel or jalap, from sixty to ninety grains of benzoate of soda dissolved in about three ounces of water, administered in twenty-four hours, for two days. The third day a slight purgation with magnesia is followed by further administration of the benzoate of soda.

During treatment the child is rigidly dieted, and nourished simply upon lemonade and a few spoonfuls of wine. Milk and bouillon are proscribed, the child, however, being allowed to nurse four times in twenty-four hours.—*Journal de Médecine de Paris*, August 23, 1885.

THE BINIODIDE OF MERCURY COMBINED WITH THE IODIDE OF POTASSIUM AS AN ANTISEPTIC IN SURGERY.—DR. LOUIS VACHER, in the *Gazette Hebdomadaire de Médecine et de Chirurgie*, of September 4, 1885, recommends the combination of biniodide of mercury and iodide of potassium, by which is formed the iodohydrargyrate of the iodide of potassium, a valuable antiseptic, especially in ocular surgery. The salt is four or five times more active than the bichloride of mercury, and the proportion required for antiseptic purposes is only 1 to 12,000. A solution less concentrated is of doubtful efficacy, while in greater strength the preparation becomes irritating and progressively caustic, delaying cicatrization, producing inflammation, and finally causing vesication, especially upon the mucous membrane.

The preparation of the remedy is, according to Bouchardat, easily accomplished by mixing equal parts of the biniodide of mercury and the iodide of potassium, adding sufficient distilled water to dissolve and evaporating, the resulting yellow needle-like crystals being the iodohydrargyrate of the iodide of potassium.

THE TREATMENT OF CONTUSIONS OF THE PERINEUM.—MAURICE NOTTA, apropos of a number of observations on the treatment of grave contusions of the perineum—with resulting traumatism of the urethra—as the result of fall, recommends the following treatment as most likely to result successfully:

1. The immediate performance of a long and deep median perineal incision, so as to lay open at once the contused region.

2. If at the end of some hours, owing to the distention of the bladder the symptoms are urgent, on account of the inability of the patient to urinate, he should be catheterized, or hypogastric puncture should be performed in case the posterior portion of the urethra cannot be found.

3. If, on the contrary, perineal incision is followed by evacuation of the bladder, during the subsequent time the patient is under treatment, direct catheterization should be practised, or search for the posterior portion of the urethra be made through the wound.—*Gazette Médicale de Paris*, September 5, 1885.

UNCONTROLLABLE HICCOUGH.—M. LIÉGEOIS, in the *Rev. Méd. de l'Est*, records the case of a young woman who, during twenty-four days, was constantly affected with hiccough. The attack supervened upon a fit of nervous excitement, and was unaffected by treatment with bromide of soda, potash, and ether, although milk and bouillon taken by the patient were not vomited. M. Liégeois, who first saw the patient on the twenty-fourth day of the attack, prescribed strong doses of chloral hydrate and hyoscyamin. During sleep the attack ceased, to be renewed on waking. In a few days the intervals between the attacks became longer, and finally returned only when the patient was excited or swallowed food or drink. A few months subsequent an abscess formed in the right epigastric region, from which a needle one and one-fifth inches was extracted; and, examination being made, M. Liégeois succeeded in discovering and removing eight additional needles, all shorter than the first, with the result of entirely relieving the hiccough. The patient pretended entire ignorance as to how the needles were swallowed.—*L'Abeille Médicale*, September 17, 1885.

EARLY PUNCTURE IN ASCITES.—EWALD, in the *Berliner Klin. Wochenschrift*, No. 16, 1885, advocates the early performance of abdominal puncture in ascites. The objections hitherto advanced against the operation, such as the debilitating effects produced by the loss to the organism of organic principles, the rapid reproduction of the fluid, fear of collapse, and peritonitis, are insignificant as compared with the advantages of early puncture.

By this operation, Ewald holds that collateral circulation is rendered easier, pressure upon the great abdominal glands, as well as that upon the heart, lungs, and intestines, removed. As a result, the functions of these organs are more easily performed, and the assimilation necessary for the support of the economy thus more readily accomplished. In addition, the use of drastic cathartics is also avoided to a greater or less extent, and their consequent evil effect upon the functional activity of the stomach and intestines.

To avoid wounding the intestines in those cases where only a moderate amount of fluid is present, a blunt-pointed trocar may be used, such as the one contrived by Ponfick for peritoneal transfusion.

The operation, Ewald further maintains, does not, as was formerly asserted, shorten the life of the patient, but acts as a palliative measure in those cases in which curative results are impossible.—*Centralbl. für Chirurgie*, August 16, 1885.

PHILADELPHIA.

SATURDAY, OCTOBER 3, 1885.

HEALTH STATISTICS OF WOMEN COLLEGE GRADUATES.

ANY effort to give material proof that the higher education of women is attained without injury to either physical or moral health will surely be welcomed. "A Report of a Special Committee of the Association of Collegiate Alumnæ" contains the most reliable mass of facts ever brought together before bearing on this important subject.

The work of the Committee appears at a very favorable time. We are having a reaction from the agitation that the book of Dr. Clarke excited; and not only educators, but, what is of even greater importance, the mass of intelligent people are beginning to take a rational view of woman's education and training for important and active positions in life. It never, to us, seemed reasonable to fear injury to the health of women for them to do those things that lie in the direction of the least resistance, and surely we may say that to pursue higher education into adult life in which congenial occupation, and mature judgment, and reasonable self-government are combined, is a safe direction for women to exert themselves in. The popular fear expressed in the controversy waged under the term "sex and education" was aimed at modern methods in the more primary stages of education, and not at higher culture and technical training.

The study of the subject in the report of the Committee is quite elaborate, and makes sufficient account of attendant conditions and individuality to give the tables scientific value. Thus, we have conditions of childhood, college conditions, and conditions since graduation, all tabulated with exactness and fairness.

It is a pleasure to note the entire absence of the special pleading which has characterized so much of the literature of this subject. On entering college twenty per cent. were below the standard of health, which was reduced to seventeen per cent. on leaving college. There are no figures, that we are aware of, to compare with this except the elaborate statistics of Neison in his work on Friendly Societies, but there is such a wide difference in conditions that their comparative value is greatly impaired. Making allowance for this difference, the ratio of good health is greatly in favor of college life for women.

Relating to more specific conditions, we find that nearly thirty-four per cent. abstained from physical exercise while at college during menstruation, which is largely in excess of women in domestic life; ten per cent. avoided physical and mental exercise at that time, which equals the disability of women in general. Of the 417 instances of disorder, we have but space to note that 112 were of the generative organs, and 137 of the nervous system, while we have but 30 instances of disorders of the brain, and 12 of the eye.

The report touches incidentally upon a subject that, from the point of view of the sociologist, is more important than a matter of individual health. The women upon whom the returns are made show a marked disinclination to marry; and those who are married have an average of but two children to a family. One thing is clear, the women of higher education will not be the mothers of a future aristocracy of intellect. This was predicted more than twelve years ago in an article on woman's relations to the professions, in the *Popular Science Monthly*. Occupation and inclination may tend to this result; but one element of their lives is so absolutely productive of it, that women of higher education and technical training will never be exempt from its operation. They are still occupied with educational work at an age when women who have selected other conditions in life are married, and are mothers.

It has been the dream of some of those who have given heartfelt work to the cause of woman's higher education, that heredity would play an important part in the future in determining through this agency, to the development of a cultured race; but a race, cultured from heredity, will emerge from the environment which has always surrounded it—a gentle, graceful home. Listen to what a talented woman has to say upon women in a relation that touches this subject very closely. Mrs. Oliphant, in her last novel, says: "Let us talk as we will of highly educated women, and of mental equality, and a great many other fine things; but, as a matter of fact, this gentle auditor and sympathizer, intelligent enough to understand without taking much part, is a more largely accepted symbol of what the woman

Digitized by Google

ought to be than thing more prominent and individual."

We do not make the quotation to disparage woman's efforts to obtain a wider horizon than the fireside or the workshop, but rather to emphasize the fact that while she may preserve her health, and even improve physically under her intellectual training, as the report of the Committee proves, her enlarged moral skyline does not confer any enlarged powers as a social factor. And she gains this at an expense to an element in her nature, the existence and gratification of which are as healthful, actively and potentially, as the functions of circulation and innervation. And yet, in this endeavor, she is the noblest example produced in a form of civilization that is becoming overtrained, and more artificial in every effort that is made to force its human product up the incline to that doubtful altitude called a higher plane. The toil is as hard, the doubt and disappointment as bitter, while the reward, by an unjust discrimination, falls much short of that measured out to her educated brothers. But if this were all, if there were not always before her, dim and undefined like a shadow, an underlying element of her nature, too sacred for words, but not too stern for tears and sighs, that makes its demands in vain, then might we say, that woman in her heroic effort for higher intellectual training and work, has not taken up a burden that for many will be, indeed, hard to bear. None knows this so well as woman herself. She is a creature alive to her emotions and reads them correctly; and knowing all this she takes up the burden of her higher culture with no doubtful or unsteady hand.

FLOATING LIVER.

LANDAU, to whom we are indebted for a most exhaustive monograph on the subject of floating kidney, has issued a companion brochure on the floating liver as associated with the pendulous belly of women. The existence of this condition has been regarded by good observers as doubtful. This was the conclusion arrived at, only a few years ago, by Wickham Legg after a review of the literature of the subject, comprising twenty cases. Landau has now collected thirty-one cases, to which he has added sixteen from his own practice. Of the published cases very many, as shown by Legg, are open to suspicion, and in some the diagnosis has been proved by autopsy to be erroneous. Suspended so closely to the diaphragm by firm ligaments, the anatomical relations of the organ seem most unfavorable to dislocation; indirectly, too, the liver is supported by the intestines filled with gas and liquid, and by the abdominal wall. The tension of the air in the lungs also aids in the suspension. In normal conditions the liver is very slightly, if at all, movable; but in pathological states it may become ante- or retroverted, or dislocated downward.

The chief cause of mobility of the organ is an absolute increase in the abdominal space, such as follows repeated pregnancies, ascites, and the removal of tumors. It is associated always with pendulous belly, and may exist in various grades. As the extent of motion is limited by the attachment posteriorly at the inferior cava, and anteriorly by the attachment to the navel, the terms dislocated and displaced seem more appropriate than floating. The author thinks that in a large proportion of all cases of pendulous belly some degree of dislocation occurs. The diagnosis does not offer serious difficulties, and though many unpleasant symptoms may occur, the persistence of the condition is not dangerous. The treatnent must be directed to the state of the abdomen, and, by proper measures of support, entire relief, if not a cure, may be effected.

PROSTATECTOMY AND PROSTATOTOMY FOR ISCHURIA.

IN the *Lancet* for July 11, 1885, may be found the details of a case of ischuria from enlargement of the median portion of the prostate, in which MR. EDWARDS afforded complete relief by punching out a portion of the obstructing outgrowth with the prostatectome of Gouley, which is a modification of the exciseur of Mercier. The operation was executed in ten minutes; there was very little bleeding; and the urine was ejected forcibly and in a good stream on the sixth day.

The operation of Mercier, despite the fact, as we are informed by Dr. Gouley, in the *Lancet* for July 17, 1880, that its originator performed it upwards of four hundred times, with excellent success, and without the occurrence of abundant, much less fatal, hemorrhage, has never been looked upon with confidence. With the exception of Reliquet and several other surgeons in France, Teevan and Edwards in England, and Gouley in this country, it appears to be without supporters. To be sure, the objections which have been urged against it are purely theoretical, and not based upon the personal experience and observations of those who condemn it. At the meeting of the American Surgical Association, held in Washington last April, Gouley, who alone in this country has any practical knowledge of the procedure, praised it so warmly that it was difficult to understand why it had not been generally adopted. From his remarks, we ourselves reached the conclusion that it is justified when the retention is complete, and when there is great difficulty or impossibility of passing the catheter, especially if the outgrowth is small. Should further experience conclusively demonstrate good results, surgeons will doubtless practise it before the patient has to resort to the habitual use of the catheter.

Digitized by Google

Should prostatectomy be looked upon with disfavor, the barrier to micturition may be overcome by internal prostatotomy with the thermo-electric cautery, or by external prostatotomy with the bistoury, as has been successfully demonstrated by Bottini, of Pavia, and Harrison, of Liverpool.

The cases of Bottini, which are recorded in the *Centralblatt für Chirurgie*, No. 28, 1885, are replete with interest. In the first, that of a man sixty-eight years of age, the cautery was held in contact with the median outgrowth for forty-five seconds. A soft catheter was retained in the bladder for four days, when it was removed, and the bladder emptied every six hours; the first spontaneous emission of urine took place on the twenty-second day; and at the end of three months the patient was in robust health; micturition was normal, and the urine was clear and acid. In the second case, that of Dr. Musatti, described by himself, the catheter was withdrawn on the fifth day; there was some scalding on the first two occasions when the bladder was emptied; the patient left his bed two days later; and Béniqué's sounds were subsequently passed until No. 44 was reached. The final result was great improvement in the general health, with micturition every five or six hours. Musatti declares that the operation was less painful than cauterization of the prostatic urethra with nitrate of silver, and recommends that it be performed without an anæsthetic agent.

Cases such as these, showing as they do the complete restoration of the power of micturition in a short time by a bloodless and comparatively painless operation, which, moreover, is not followed by febrile symptoms, certainly entitle thermo-galvanic prostatotomy to a careful and extended test.

The objection to this procedure (but it is purely theoretical), is that the relief may not be permanent, from the fact that cicatricial tissue the result of a burn oftentimes exhibits a great tendency to undergo undue contraction. Hence, in such cases, we should deem it wise to keep the part fully dilated by the methodical passage of large steel bougies during the remainder of life.

In the operation of Harrison, the membranous urethra is opened by a median perineal incision; the obstructing portion of the gland is then divided, partly with a straight probe-pointed knife, and partly by divulsion with the finger or a large-sized bougie, until the access to the bladder is felt to be free; and the edges of the wound are kept apart by a gum-elastic tube, through which a smaller tube is passed to conduct off the urine. The tube is retained for a number of weeks, or until a catheter can be made to enter the bladder easily along the natural route; and, on its withdrawal, the use of a large bougie is continued until the perineal wound has soundly closed, and afterwards it is passed occasionally as a precautionary measure.

In a paper read at the International Medical Congress at Copenhagen, Harrison narrated a case in which he had performed the operation above described. It was one of atonied bladder and ischuria from a nipple-like projection of the median portion of the prostate, in an old man of very childish habits, who could not be made to retain a catheter. The patient was able to go about in ten days, when the cystitis had disappeared, and the urine was discharged at will by turning the tap connected with the drainage apparatus, which was worn for eight weeks. After the closure of the perineal wound, he could retain urine for four hours, the bladder acquired its natural power of expulsion, and there was no residual urine. At the expiration of six months, the man had a paralytic seizure, but it was not found necessary to resort to catheterism.

It will thus be seen that the result was most gratifying, although a more unfavorable case could scarcely have been subjected to operation. The advantages of this over the procedures of Mercier and Bottini are that the nature of the obstruction can be accurately determined through the perineal wound, and that the division of the obstruction can be made with a degree of certainty and precision which cannot be attained with the prostatectome or the galvanic cautery.

A careful perusal of the cases to which we have directed attention must convince the impartial surgeon that the operative treatment of median prostatic hypertrophy when it does not yield to catheterism has been too much neglected. We regard this as a great and comparatively new field of operative surgery, and we trust that our remarks may have the effect of awaking attention to the subject, and of inducing surgeons to give these operations a fair trial.

PHOSPHORUS IN RACHITIS.

THE remarkable results obtained by KASSOWITZ have induced a widespread trial of this remedy in rickets, and recent German journals contain several important articles upon the subjeet.

HRYNTSCHAK, in twenty-four carefully studied cases, has seen very little good from its use : only five cases were benefited. SOLTMANN, in sixty hospital and ten private cases, found an early improvement in nutrition and muscular strength, which he attributes to a general stimulation of the tissue changes, and not to any specific action of the drug on the bones. He has never seen enteritis follow its use; on the contrary, the gastric and intestinal symptoms disappear, and as do also the nervous symptoms and the bronchial catarrh. HEUBNER is of the same opinion, and doubts if there is any special action on the bones and teeth.

Digitized by Google

MONTI holds that the diverse views which prevail on the value of phosphorus result from different interpretations of the phenomena. Those who, like Kassowitz, record prompt and satisfactory action of the drug base their opinion on the improvement of certain symptoms—the healing of the craniotabes, the ossification of the sutures, and the cessation of the laryngismus, etc.; but it is well known that the individual symptoms may disappear while the disease itself continues, or even progresses rapidly in other parts. We can speak of a cure only when the circumference of the head and thorax, and the length and weight of the body, become normal. When the rate of development and the general condition of the children are included in the circle of observation, we find the drug practically useless. EISENSCHITZ, on the contrary, believes, with Kassowitz, that phosphorus has a specific effect in counteracting the injurious agencies which impair the nutrition of the ossifying cartilages.

While, then, the general experience does not seem at all favorable to this plan of treatment, it is only fair to note that the number of cases (1224) treated by Kassowitz was very large, while the opposing results have been obtained from a much smaller series of cases, and we must await further observations before we can decide positively upon the value of the drug in this disease.

THE MEETING OF THE AMERICAN GYNECOLOGICAL SOCIETY.

THE last meeting of the American Gynecological Society was well attended, both by members and by visitors, and its work quite creditable. It presented a striking contrast with the previous meeting at Chicago in at least two respects: First, having a quorum it transacted the business belonging to it. Second, all papers whose authors were present—only two of thirteen gentlemen whose names were on the programme being absent—were read, none of them being crowded out by discussions of other papers protracted beyond their allotted time. The Society ought to be careful not to repeat the injustice which has been done in denying a member, who comes with a carefully prepared paper, the right of reading it because others have occupied so much time in extemporaneous talk. Every medical society has men who are heard not only for their much speaking, but for their many speeches—they are equally at home on every subject, and are always ready to present their views freely and fully. Unfortunately, valuable as their speeches may be, the society hears them at the expense, sometimes, of papers announced on the programme, which are finally read by title, a sort of reading very much like neglectful, if not contemptuous, silence, which may cause heartburnings, if not permanent alienation.

Another feature of the Washington meeting was the marked absence of western members, only two being present; this ought not to have been so, but as each of the western gentlemen present was honored with an important office, the Society plainly showed how highly it esteemed them.

The papers read were, as a rule, brief, clear, and pertinent. Long papers read before a medical society are usually big blunders, and they are more apt to weary and confuse than to interest and instruct. Indeed, we think it would be wise to limit all papers to thirty or forty minutes; few men can safely, so far as clear information and a favorable impression are concerned, transgress the latter time unless a varietyof topics is discussed.

The retirement of Dr. Foster from the secretaryship is to be regretted, though his place is to be occupied by so excellent a successor as Dr. Taber Johnson.

The Society, in its ten years, has accomplished much; its financial condition is good; its continued usefulness and increasing honor are certain.

SOCIETY PROCEEDINGS.

RHODE ISLAND MEDICAL SOCIETY.

Quarterly Meeting, held at Providence. September 17, 1885.

(Specially reported for THE MEDICAL NEWS.)

THE PRESIDENT, DR. O. C. WIGGIN, IN THE CHAIR.

DR. E. T. CASWELL submitted the draft of an

AMENDMENT TO THE BY-LAWS

of the Society, designed to elevate the standard of admission to fellowship, by the following provisions: 1. The Board of Censors on receiving the application for admission of any person as a Fellow of this Society, and after duly examining his diploma, provided it emanated from some medical college of known and acknowledged respectability, and satisfying themselves that he does not profess or intend to practise any exclusive system of medicine, shall refer the candidate to the *Board of Examiners*, and on the receipt of a favorable report of the examination passed, shall recommend him for election. 2. Examinations for admission to this Society shall be conducted by a board of five members to be appointed by the President at the annual meeting. Each year the senior, by appointment, shall drop out, and his successor shall be appointed for five years. The senior, by appointment, shall be the President of the Board. 3. Examinations shall be held in the month of April of each year at such time and place as may be convenient to the members of the Board, and shall embrace the usual branches of medical science taught in recognized medical colleges. The candidate will be required to show that he has an adequate knowledge of the Latin language and has received a good English education. 4. The Board will examine only such candidates as have been referred to them by the Board of

Digitized by Google

Censors, and will report to the Censors the resul o the examination during the first week in May.

The amendment was unanimously adopted.

DR. HERBERT TERRY, of Providence, read a paper on the

PREVENTION OF LACERATION OF THE PERINEUM.

Several noted authorities were quoted on the cause of this laceration. Dr. McCaw, of Providence, had suggested the theory that it might be caused by contraction of the perineal muscles brought on by the pain from distention.

The writer thought that in his own cases the accident had occurred oftenest during the passage of the shoulders, but perhaps as often just at the last moment when the perineum was distended over the lower part of the face. It had also seemed more frequent in case the head was considerably elongated. His conclusion was that laceration is not so often due merely to distention, but to the shape of and direction taken by the distending part.

Dr. Terry explained as follows: "When the progress of the head is stopped by the nape of the neck catching under the arch of the pubes, further pains act upon the head as upon a lever of the third class with the fulcrum at the occiput. The face does not emerge, as the occiput, in a direction perpendicular to the plane of the vaginal orifice. It hooks up the perineum, as it were, from behind and presses upon it, not evenly over its whole surface, as did the round occiput, but over a limited area and in a direction more nearly perpendicular to the surface of the perineum. The more elongated the head the more evident does this lever-like action become. The same conditions hold true in the passage of the perineal shoulder. The narrow presenting part has often seemed to come directly through the perineum without distending it too near its maximum. I am convinced that the parts often begin to tear along the vaginal wall. In one case the rent was distinctly felt after the head had receded and the perineum had contracted." For the prevention of laceration, the writer mentioned the use of lubricants when the parts had become stiff and dry in protracted cases, and also repressing the head during a pain by means of the fingers of the left hand carried over the side and between the legs, while, during the interval, the head is slowly urged forward by one or two fingers of the right hand acting through the recto-vaginal wall.

The writer then said, "acting upon the idea spoken of above, that the lacerations often occurred from the shape and direction of the presenting part, I have used in the last three cases of primiparæ that I have attended, an appliance made for me at one of the rubber stores. It consists of a piece of steel three-quarters of an inch wide and eight and one-quarter inches long, embedded between two strips of soft rubber, vulcanized together, and projecting in every direction three-quarters of an inch beyond the edge of the piece of steel. This makes a plate nine and three-quarters inches long, two and one-quarter inches wide, and a little less than one-sixteenth of an inch in thickness. It is perfectly flexible, and cannot injure the soft parts of the mother, while the steel shank gives sufficient firmness to the centre to distribute the pressure more evenly over the perineum. It does not interfere perceptibly with the relaxation of the parts by dilatation of the anal orifice, nor does it seem to retard the passage of the child."

Two of the three cases in which the appliance had been tried were said not to be test cases. The remaining case was described as follows: "The perineum I found was one which you will recognize as prone to tear—short, thick, rigid, and apparently set back from the other parts of the vulva. During the course of the labor the head became wedged, apparently between the two tuberosities of the ischia, and it was quite difficult to introduce the forceps through the vulva. After the head had been brought down so as slightly to distend the perineum, the instrument described was well oiled and slipped in between it and the head. The forceps were removed and the head was born after a few pains. During the pains the head was repressed as much as possible, while during the intervals it was carefully and gradually pushed forward by two fingers in the rectum. The orbits, mouth, and eventually the chin were felt through the soft rubber and recto-vaginal wall and were successively acted upon. Upon the birth of the child, the parts did not, as usual, contract forcibly around the child's neck and in front of the shoulders, but were already somewhat distended by the elasticity of the steel shank and the pressure was distributed over the whole, instead of being limited to the portion well back in contact with the point of the shoulder.

"In cases where the head is born last, the body of the child can be carried well forward, and the mouth brought to the vulva, so that air may be obtained, and then plenty of time taken in the delivery of the head. When rapid delivery is necessary, drawing the perineum forward, as recommended by Dr. Goodell, or carrying it forward by Playfair's method will, probably, lessen the degree of laceration. In other positions of the head than occiput anterior, a long diameter is presented at the vulva, and rupture is likely to occur from mere distention. Deliberation in this delivery is of the greatest importance, and a liberal supply of ether or chloroform will reduce the risks of laceration. In the use of forceps it is rarely necessary more than fairly to distend the perineum before removing them; and it seems to me that the risks of laceration are much increased by not doing so. Very many consider, however, that the head may be delivered with forceps with greater safety to the perineum, because the head is held well forward under the arch of the pubis."

DR. D. H. BATCHELDER said he did not believe much in the efficacy of supporting the perineum. It had for many years been his practice, in case of an unyielding perineum, to inject per rectum, gr. ½ or 1 of antimony in tincture of lobelia and starch water, which will cause the parts to yield in twelve or fifteen minutes. Out of 3780 obstetrical cases, he had encountered only 4 cases of ruptured perineum. He thought much trouble in this direction came from the too early use of ergot or the forceps.

DR. CALDWELL reported

A CASE OF LITHOLAPAXY.

The man was sixty-four years old, and had had symptoms of stone for two years. The fragments weighed 160 grains. Time of operation one hour. The man sat up at the end of a week, and resumed business one week later.

Digitized by Google

DR. WILLIAM H. PALMER showed a specimen of

OSSIFIED OVARY.

Its length was $1\frac{3}{4}$ inches; breadth, $1\frac{2}{5}$ inches; weight, 278 grains. It was removed from the body of a woman aged thirty-five, who died suddenly of heart failure, caused by fright at the breaking of a lamp chimney near her bed, two weeks after her first confinement, from which she had seemed to be recovering well. In the specimen ossification was complete, the whole organ being as dense and hard as bone from any part of the body.

DR. G. D. HERSEY read an excellent paper on the

AFTER-TREATMENT OF TRACHEOTOMY.

The scope of the paper did not include cases where the operation was done on account of foreign bodies, or constriction due to growths, etc., but only cases of fibro-membranous disease, and the more accurate title would be "the treatment of tracheal diphtheria after an opening has afforded access to the lower tracheal region."

Immediately after the operation hypodermatic injections of brandy are usually indicated. The patient should be in a large airy room, warmed by an open fire or a base-burner coal stove; all cooking or other work that might cause irritating qualities in the air should be prohibited near the sick room.

From the poisonous nature of the disease, stimulants and forced feeding must be largely relied on. Brandy and milk must be given freely as soon as the patient recovers from the anæsthetic, and rectal feeding employed if indicated. After a few hours remove the inner tube and clean it with a whalebone swab or some instrument flexible and yet firm. "Whenever symptoms of obstruction occur, untie the tapes and remove both tubes, thus gaining free access to the trachea, and try to remove the rattling mucus with the whalebone swab or spongeholder." If there is tough, stringy, muco-pus, and membrane which is too firmly attached to the trachea to be separated by the swab, try the curved forceps. These measures will probably suffice for the first twenty-four hours. But as the disease progresses, more and tougher membrane is formed, filling the trachea and blocking up the lower end of the canula. The child has a violent, strangling cough, and, starting up to a sitting posture, vainly attempts to expel the tough membrane through the canula, and sinks back exhausted. Again and again Nature thus tries to relieve the obstruction, mutely imploring the surgeon's help. Passive œdema of the lungs will soon follow such violent efforts at respiration, and coarse râles can be heard over both lungs.

It is because this condition may come on soon after the operation, and at any time for three or four days afterward, that the medical attendant or a competent trained nurse ought to remain constantly with the patient for four or five days and nights following tracheotomy. Death will surely follow a few of these strangling scenes unless prompt relief is afforded, and, happily, the relief is generally possible. First, steam is the best sedative to this excessive broncho-tracheal irritation. If the room is heated by steam, the pipe may be tapped and steam conveyed by a rubber tube to the bedside. The steam atomizers and portable boilers often recommended, are worthless. They frighten young patients, and are wholly inadequate for producing the large volume of steam required.

An efficient apparatus may be extemporized as follows: Build a tent of sheets over the bed or crib, and let the tent reach to the floor so that the steam will not escape. Under the sheet and beside the bed place a wooden water pail containing three or four pounds of unslaked lime in lumps, and add a gallon of boiling water, stir well, and the tent will soon be filled with a dense volume of steam at a temperature of about 90° F. This hot, moist atmosphere is very grateful to the patient. After five minutes steaming, or longer, if the breathing and cough continue dry and harsh, remove the tracheotomy tube. Through the opening the surgeon may pass a dull copper curette and thoroughly scrape the mucous surface of the trachea down to its bifurcation. By going carefully around the entire circumference of the windpipe, and even into the bronchi if necessary, he will scrape off and out of the trachea an abundance of tough, fetid membrane, which he must be prepared to catch the instant it appears at the mouth of the wound, or it will be sucked back with the next inspiration. The tubes may then be cleaned, carbolized, and replaced. The child is relieved, tries to whisper that he wants a drink, and breathes quite freely for a few hours. Then the wheezing, rapid respiration comes on gradually, and the terrible strangling scene is repeated, to be relieved by the same measures as before. This struggle may go on every four to six hours for five days before the tough membrane gives way to a catarrhal secretion. Various complications may arise. After two or three days the epiglottis, from disease or disuse, fails to shield the larynx, and milk runs down the trachea, setting up violent coughing, and oozing out around and through the canula. At this time it is better to feed wholly by rectal injections. Or the canula may press against the œsophagus, causing obstinate vomiting and requiring the removal of the tube for a few days. Capillary bronchitis or pneumonia may occur, though not usual during the first three or four days. The usual treatment should be employed.

The greatest care must be taken to secure absolute cleanliness of the patient, his neck and wound, the tubes and tapes, the night dress and bedding. In no surgical procedure is a faithful, skilful nurse more necessary than here. Milk, alcohol, ammonia, digitalis, and iron are the sheet-anchors in this disease, and must be pushed to the utmost tolerance of the patient. Digitalis is needed essecially, because the labored respiration taxes the heart severely. Bromide of sodium or spts. lavand. and ether will often be needed to allay nervous restlessness.

Diphtheria of the wound is a complication that sometimes occurs, and is treated by frequent removal of the tube, and cleanliness. Dusting powders are not applicable to the wound, but iodoform or alum, mixed with glycerine, may be painted over an unhealthy surface, and dilute tincture of iodine can always be brushed lightly over the edges of an advancing inflammation. Sucking the wound with the surgeon's lips to remove false membrane is generally more foolhardy than necessary. Steam, the dull wire curette, the curved forceps, and the flexible whalebone sponge holder are adequate to relieve even the most desperate cases.

The writer then described two cases in point.

Digitized by Google

Case I.—I was called hastily on the third day after the operation, and found the boy (six years old and delicate) exhausted by a recent struggle, lying back on his pillow unconscious, pulseless, making occasional shallow efforts at breathing, and rapidly dying from asphyxia. I injected three or four ounces of brandy hypodermatically, removed the tube, and, with the curette, pulled out several pieces of tough membrane, which, partially dried, had occluded the trachea, and plugged the lower mouth of the canula. More membrane was got out, and half an hour later the moribund boy, resuscitated, drank a glass of milk, and slept quietly.

Case II.—A five year old boy had diphtheritic croup, for which a surgeon performed tracheotomy. He did fairly well for three or four days, and then the trachea and bronchi filled up with membrane and tough secretion which the patient could not expel, and which gradually made respiration impossible. The two attending physicians gave up the case as hopeless, removed the tube as the patient was dying, and gave ether merely for the sake of euthanasia. I was sent for after both the other physicians had left the house, and found the body laid out on a table as dead. The only sign of life was a slight, convulsive gasp about every ten seconds. The boy was speedily put into hot blankets, the tent was thrown over his crib and filled with hot steam, and brandy given freely by hypodermatic injection. Resuscitation was slow, but the heart responded to the stimulus of alcohol in the circulation, the steam softened the dried, tenacious exudate, and the curette cleared a passage to the lungs. Helped by prolonged steaming, our reviving patient coughed up considerable membrane and stringy mucus, and, in about two hours, sat up and drank some milk punch. His convalescence was interrupted by an attack of pneumonia, but he made a good recovery. I am sure that neither of these two lives would have been saved without the use of the curette. The membrane, especially that attached near the wound, becomes dried and tough, and chokes the middle and lower trachea, clinging more and more tenaciously on the second, third, and fourth days after the operation, while the diminishing strength of the patient makes him less and less able to expel it. The curette clears out this obstruction more effectually than any other instrument, and I have never seen its use cause pain, or hemorrhage, or strangling.

A vote of thanks was tendered Dr. Hersey for his valuable paper, and the meeting then adjourned.

CANADA MEDICAL ASSOCIATION.

Eighteenth Annual Meeting, held at Chatham, September 2 and 3, 1885.

THE PRESIDENT, WILLIAM OSLER, M.D., IN THE CHAIR.

(Specially reported for THE MEDICAL NEWS.)

MEDICAL SECTION.

WEDNESDAY, SEPTEMBER 2D.—FIRST DAY.

DR. GRANT, of Ottawa, read the report of a case of

ANEURISM OF THE AORTA.

The patient was an old soldier who had suffered from thoracic pain and other symptoms. The disease was readily diagnosticated, and he was under observation for a long time, during the greater part of which he was able to do light work. A large projecting tumor was watched, bulging the sternum and costal cartilages, and ending by eroding these and forcing itself forwards as a mass as large as two fists. He finally died from cerebral embolism.

DR. GEO. ROSS remarked upon the fact that this man had lived a long time—nearly five years—from the onset of symptoms. In the treatment of the case moderate exercise had always been allowed. Dr. Ross believes strongly in insisting upon complete rest for a sufficient length of time, although the present example shows that this is not always necessary to secure a remarkable degree of longevity. The reason here for the long time the man lived was plainly that the aneurism grew from the front of the aorta and pushed forwards, thus avoiding the important centrally situated structures. Dr. Ross inquired whether the physical sign of "tracheal tugging" had been observed. Dr. Grant said it had not been looked for. And in answer to a member, Dr. Ross explained the method of examination to detect "tracheal tugging," and said that he considered the sign one of great value in the diagnosis of aortic aneurism. If present, it seemed to be almost pathognomonic, for he had examined for it in a great number of hospital patients, and had never found it distinctly marked in anyone who was not the subject of this disease. It is quite true, however, that it is absent in many cases of aneurism, for the conditions necessary for its production are, that the tumor bear against the trachea or a large bronchus, and, secondly, that it be not completely solidified.

DR. SHEARD spoke of a case recently under his care. The tumor sprang from the first part of the arch, and the symptom most marked was dyspnœa in severe paroxysms from spasm within the larynx. Prolonged rest appeared to have had a very beneficial effect; this was strictly enforced for three months. Dr. Sheard had used potass. iodid. in pretty full doses, but its employment was always followed by marked depression and lowering of the pulse—so much so that it had to be discontinued. He thought this action of the drug unusual. Dr. Sheard also gave the particulars of a case of aneurism in the descending thoracic aorta which produced plugging of all the great vessels beyond its point of origin.

DR. OSLER remarked upon the importance of considering the question of prognosis in these cases. Dr. Grant's case, for instance, had lived five years and a half, and he had known men with large tumors to live ten years and more. On the other hand, a small aneurism may quickly burst and prove fatal; so much depends upon the location of the growth—those growing anteriorly may attain large dimensions before producing symptoms, and even then life may be prolonged, whilst a small tumor centrally situated generally soon makes its presence known, and is apt to kill within a short time. Those growing from the transverse arch and backwards are likely to produce early symptoms, and quite frequently early death. Those, again, involving the descending part of the arch may last very long. He would also in this case notice the coexistence of disease of the aortic valves, which was by no means common. The absence of any marked degree of hypertrophy of the ventricle was in accordance with what is generally

Digitized by Google

seen. As regards iodide of potassium, he was satisfied of its great power in relieving the pain so frequently present, but has great doubts as to its assisting in the consolidation of the tumor.

DR. WILKINS spoke of the necessity for limiting the amount of fluid to be allowed to these patients, and alluded to a case of his own in which this principle had been acted upon, and where the man had lived between four and five years.

He would advise reducing the allowance to half a pint *per diem*. He thinks that the necessary result of free imbibition of fluids is distention of the sac for the time being, a condition, of course, unfavorable to cure. In the case alluded to, the "tracheal tugging" had been a marked sign, and the patient died from rupture into the trachea.

DR. ECCLES alluded to a case where he had been obliged to omit the use of iodide of potassium on account of its always rendering the pulse very small and frequent.

DR. WORTHINGTON then reported some cases of

EPIDEMIC CEREBRO-SPINAL MENINGITIS.

He remarked that though the cases he related were indicative of a cerebro-spinal fever, and seemed identical with the so-called epidemic form, they were not sufficiently numerous to show that the disease was extensively prevalent. The notes were then read *in extenso*. The first showed a markedly intermittent type, and it was thought that here, as according to Dr. Radcliffe sometimes occurs, the specific disease was complicated with ague. The other cases were characterized by rapid onset, rigors, headache, rachialgia, convulsions, spasms, and delirium, and later on, somnolence and diplopia. They presented a considerable degree of similarity. The treatment consisted in mercury and iodide of potassium, with application of cold. In later stages, quinine and stimulants.

DR. HARRISON said that it was somewhat remarkable how this disease showed itself in certain restricted localities. He had had six cases, and Dr. Stark, in his neighborhood, seven, four of which had proved fatal.

DR. OSLER said that in the absence of *post-mortem* records it was impossible to be certain of the diagnoses. The cases he had met with in cities and elsewhere were all *sporadic*. Those which he had examined autopsically he found to belong to one of two classes, (*a*) simple, and (*b*) tubercular. The former were rare; the latter were distinguished by a more prolonged course, and by being sometimes actually latent. He had recently had charge of a sailor, who having fallen heavily upon the deck of his ship, soon after developed spinal symptoms which were supposed to be due to the injury. The autopsy, however, showed tuberculization of the spinal and cerebral meninges, almost certainly of pretty long duration. The specific fevers also not unfrequently simulate cerebro-spinal fever, especially the malignant form of smallpox and of typhoid fever. The symptoms in all these cases are almost, if not absolutely, identical, and an autopsy alone can set a doubtful case at rest.

DR. TESKEY related a case of tubercular trouble he had lately had which might during life have readily passed for one of cerebro-spinal fever. It began with convulsions, followed by opisthotonos and then coma. The necropsy showed tubercular meningitis complicated by an abscess in the occipital lobe of the brain.

DR. MACDONALD, of Hamilton, spoke also of the necessity for *post mortems*, and deplored the tendency amongst country people to object to this proceeding. During epidemics of cerebro-spinal fever in Hamilton he had a number of autopsies. Whenever the diagnosis proved correct he had found distinct evidences of inflammation of the cerebral and spinal meninges without any tubercle. In several cases the negative conditions discovered pointed to some specific febrile poison as having caused the symptoms.

DR. ARNOTT, of London, Ont., read a paper on

THE SOURCES OF MALARIA.

The existence of malaria is very generally taken as equivalent to presupposing the existence in the same place of a certain germ. It is commonly accepted that one of the chief requisites for malaria is decomposing vegetable matter. The only circumstances required for this to take place, and, therefore, for the generation of malaria, are thought to be the presence of water, exposure to air, and a certain temperature. Dr. Arnott thinks that decomposing vegetable matter is *not* necessary, but that with water and the requisite degree of heat the germ of malaria will be propagated. He thinks, therefore, it is conceivable that this might take place even in distilled water. Many arguments were adduced in support of this view. In different districts the prevalence of ague is not at all proportionate to the amount of vegetable matter in a decaying state. One may find the latter in great abundance with hardly any intermittent, whilst *vice versa*, malaria may abound where decaying vegetable structures may be said not to exist, or to be very sparingly present. Loomis believes that malaria is proportionate chiefly to the heat and moisture without reference to the organic matters. The effect of drainage of land is well known. Phthisis and cholera will thrive under the same physical conditions as give rise to malaria. The writer again emphasizes the opinion that heat and moisture are really the only essentials required to propagate malaria independent of the presence or absence of organic matter.

DR. INGALLS, of Detroit, remarked upon the conditions present in that city. There, the parts built upon consist of a black organic mould, six or eight inches deep, underlaid by a heavy clay subsoil. The superficial drainage is very often defective, and moisture is retained beneath the houses for a long time. This gives rise to many diseases of a malarial type: true intermittent fever, phthisis, diphtheria. Sunlight probably plays but a small part. These malarial diseases prevail when the damp decaying vegetable loam lies under the houses, obtaining only the heat from the general atmosphere. Do we not often fail to recognize malaria in the causation of phthisis, overlooking altogether the miasmatic origin of the latter?

DR. TESKEY said, as regards the bacterial origin of malaria, the points chiefly urged in favor of the view were, that successful inoculations had been made upon animals; and that upon curing the disease with quinine the bacteria had disappeared. The natural history of bacteria in general bore upon the subject under discussion. To cultivate bacteria, heat, moisture, and some nitrogen-bearing substance are necessary. Some get it from the atmosphere, some from albuminous bodies (broth, etc.). Then, in almost every stream we

Digitized by Google

should find spores and albuminoid bodies of some kind. When there is much vegetable matter there is generally much albuminoid matter. There is certainly much yet to be known of the natural history of these particular germs.

Dr. McCulley alluded to the persistence with which malarious affections stick to certain houses. There is always some one sick in them. Often, on examining such premises, one finds decaying timbers and low sills. In these places typhoid fever and diphtheria may alternate with the true malarial affections.

Dr. Baker, of Detroit, spoke of the system in vogue in the State of Michigan. The Board of Health receives reports regularly from one hundred physicians in different sections. On comparing these it is found that malaria prevails most when the fluctuations of temperature are greatest, therefore temperature alone seems to control intermittent fever. The difference between the day and night is greatest in summer—it increases as you go South. In the northern part of the State there is no ague. He would strongly urge their system of collecting facts bearing on this disease; it is the only way in which our knowledge can be helped on. He does not consider that the bacillus can yet be accepted as proven.

Dr. Harrison said that in old times in his part of the country, all the cases of pneumonia had a malarial tendency. Now this is not observed, and there is no ague there.

Dr. Stalher mentioned the occasional occurrence of severe attacks of ague during the greatest cold of winter, as opposed to the view that a certain temperature is necessary.

Dr. Ross held that to benefit by this discussion we must restrict it to that of malaria alone. Such affections as some had spoken of—phthisis, typhoid, and diphtheria—are all believed nowadays to be produced by special organisms, having a natural history of their own. In many places these prevail to a very considerable extent, whilst malaria is unknown. It is clear, therefore, that it is not right to quote their existence as indicative of a miasmatic or malarial, although, certainly, of unwholesome conditions.

Dr. Clark said that he had observed these facts in his neighborhood. Near Oakville there is neither phthisis nor malaria. In Oakville they both prevail. The temperature on the lake shore is low, whereas, two miles or so inland it is comparatively warm.

Dr. Arnott, replying, said that the recent views of Loomis quoted, showed that the current of general opinion is towards the view that the factor of decaying vegetable matter in the production of malaria is not an *essential* one. As regards occurrence of an attack of ague in midwinter, he thought that such cases are to be explained as showing the possibility of prolonged *latency* of the poison, the attack being induced by the depressing action of intense cold.

Dr. Holmes, of Chatham, read a paper entitled

OBSERVATIONS ON PUERPERAL MANIA.

The paper alluded first, in a general way, to the causes to which an attack of this kind may be attributed. They are chiefly heredity, anæmia, and moral influences. To these he would add another, viz., *laceration of the cervix uteri*. Some objections to admitting this would occur at once; such as, lacerations are very frequent, without the occurrence of mania, which is rare. Recovery from mania often takes place without a laceration's having been cured, and most lacerations heal of themselves, or, at any rate, without treatment, become covered with mucous membrane. Dr. Broca has taught that the central sympathetic nervous system governs man's moral nature. Abdominal disease commonly produces great depression, in marked contrast to the hopefulness of those with thoracic disease. The pregnant woman is really like dry fuel, waiting only the application of a match to burst into flame. *Case I.* Mania three days after confinement; put under restraint; moderate laceration of cervix; died insane after two years. *Case II.* No heredity. Easy labor; after five days melancholic and morose; after three months much worse; suicidal; a laceration which was discovered was treated, and the mania disappeared rapidly. *Case III.* Very violent; after two weeks was sane; remained despondent for two years; then laceration was found; restored to health. *Case IV.* Became insane twenty days after labor; extensive laceration; treated with hot water douches, etc., and a rapid cure effected. *Case V.* Was seen eight months after confinement; was weak, mind affected, melancholy; slight laceration treated; after four months this was entirely healed, and she was quite well. *Case VI.* Was in an asylum; after the cure of a bad laceration was well and went home. Twelve cases in all were presented, of which the above are fair specimens. Dr. Holmes concludes that laceration of the cervix is a frequent cause of puerperal mania, and one which has been hitherto overlooked. He thinks it is of much importance that there should be a gynecologist to every asylum for the insane, and that their investigations into this subject might throw much light upon the somewhat obscure etiology of this affection.

Thursday, September 3d.—Second Day.

The Section opened at 11.30 A.M., Dr. Harrison in the Chair.

Dr. J. E. Graham exhibited a specimen of

DISSECTING ANEURISM,

and related the history of the case. The patient had been a soldier in the British Army and was wounded in the trenches, and soon after was invalided and told to avoid exertion as he might die suddenly. Aneurism at the time was evidently suspected if not diagnosed. He recovered health sufficiently to enable him to earn his living, though never strong. He had been under Dr. Richardson's care in Toronto Jail on several occasions, and it was known that he was the subject of thoracic aneurism. A few days before his death there was hemorrhage from the lungs. The condition found post-mortem was as follows: The ascending and transverse portions of the arch were much distended, and immediately beyond the orifice of the left subclavian there was a saccular dilatation adherent to the lung, and at the upper part was a laceration into the tissue which communicated with the bronchial tubes. At the distal portion of the sac were two openings, one of which communicated with the natural lumen of the vessel and the other with the dissecting aneurism. This latter was formed by the blood finding its way through

Digitized by Google

the middle coat of the vessel and dissecting the inner portion of the media from the outer half of the media and the outer coat. This was continued in almost the entire circumference of the vessel, and extended throughout the thoracic and abdominal portions to the bifurcation where by a large opening the dissecting aneurism again communicated with the lumen or the aorta. Some of the branches of the abdominal aorta communicated with the inner tube, others only with the outer dissecting aneurism. Among the remarkable features of the case are (1) the length of time which this has lasted, probably thirty years at least: the condition of the lining membrane of the dissecting aneurism shows it to have been long in existence—as it is smooth and firm almost like the normal lining membrane, only a little uneven. (2) The unusual extent of the aneurism, involving the entire length of the thoracic and abdominal portions.

DR. WILKINS presented a series of microscopical specimens illustrating

THE BACILLI OF TUBERCULOSIS,

and the fact of their communicability. The first of these were taken from the sputa of a patient suffering from chronic phthisis; the second from the lungs of the same person; the third from a rabbit, which had been inoculated with the tuberculous matter in the anterior chamber of the eye. In each case the bacilli were extremely well shown, and the demonstration was much appreciated by the Section. Dr. Wilkins read some notes descriptive of the experiments he had made on this subject, and pointed out how strikingly such observations exhibited the contagious character of tuberculous matter, and the association with it in every case of the characteristic bacilli which have been so fully described.

DR. J. E. GRAHAM said that he had been much interested in this very satisfactory and complete demonstration of the microörganisms of tuberculosis. It is a fact that some in the profession are still sceptical concerning these tubercle bacilli, whereas an examination of such specimens as these would carry conviction even to the mind of a layman without any special knowledge of the subject.

DR. JAMES STEWART read a paper on

THE CURABILITY OF THE CHRONIC FORM OF INFANTILE PARALYSIS (POLIOMYELITIS ANTERIOR CHRONICA).

The development of the paralysis had been slower and less febrile than in many instances observed, and had been preceded by diarrhœa. The patient was treated with galvanism, and made a good recovery. Dr. Stewart thinks that cases of this character are more amenable to treatment than those with more rapid and acutely febrile onsets. He advised persistent and careful treatment with galvanism, instead of consigning them, as is so often done, to the category of cases for which nothing can be done.

DR. HOLMES considered the case of value, as encouraging the general practitioner to persevere, in the hope of ultimately restoring limbs threatened with permanent paralysis. He inquired whether any other form of treatment in addition was serviceable; also what the reader's views were as to the pathology of the affection.

DR. STEWART, in reply, said that galvanism is the only thing to be relied upon. It is not definitely known whether the changes are primarily inflammatory or purely degenerative. As regards prognosis, it is important to separate the acute from the subacute and chronic cases.

DR. MCKEOUGH, of Chatham, read a paper on

THE USE OF PILOCARPINE IN PUERPERAL ECLAMPSIA.

Three cases were detailed, the principal features of which were as follows: *Case I.* Patient, when seen, had had twelve convulsions, was comatose, and greatly œdematous; the urine loaded with albumen; an attempt at venesection failed; then pilocarpine was given hypodermatically. There was profuse sweating, but at the same time copious bronchial secretion, with loud rattling. The condition became alarming, and the patient died three hours after. *Case II.* At eighth month. Considerable œdema present; passed only one ounce of urine in twenty-four hours; gave purgatives and potassium citrate with digitalis; had vapor bath. Eclampsia supervened; gave ʒj fluid extract of jaborandi with good effect. Convulsions continuing, gave morphia sulphate gr. ¼. No more convulsions. *Case III.* Convulsions occurred the day before confinement; found semi-comatose; no œdema; urine solid on boiling; gave gr. ⅛ pilocarpine hypodermatically. At night gave chloral. Next day had no return of convulsions, though she remained lethargic, and was successfully confined. Dr. McKeough considers the use of jaborandi in these cases only an experiment. Barker and Thomas think it of doubtful service. The great depression it produces is against it, whilst in certain conditions the danger of pulmonary œdema and profuse bronchial secretion are great, as shown in Case I. He thinks, from his experience, that it may prove of considerable benefit when used early in cases in which convulsions are likely to occur.

DR. MCLEAN said that though most cases of puerperal eclampsia are uræmic, they are not all so. Some arise from peripheral irritation, and resemble the fits which children have from worms and other causes. A case of his illustrates this fact. A multipara, in whom the abdomen was much distended, had convulsions; there was no albumen in the urine. He gave chloroform and delivered; no more convulsions occurred. He considers chloroform the most valuable agent, as it allays irritation of the peripheral nerves and nervous system generally.

DR. WHITEMAN was opposed to evacuation of the uterus. His practice is to leave the case to nature, except an emergency call for interference.

DR. GEORGE ROSS said that the subject always commanded a lively interest. He thought that, in the treatment of puerperal convulsions, a wrong idea was often made its basis. It is said that the blood is poisoned by a foreign substance—urea, and this must be got rid of. This in itself is even yet an unproved hypothesis. At any rate, he believed that, convulsions existing, the primary object of the practitioner should be to allay the irritation of the nervous centres, independent of everything else; accomplish that, and the eclampsia will cease, and then you will have time enough to take steps for unloading the system and starting the action of freed kidneys. To allay this central irritation we must resort to narcotics, and especially morphia and chloral hy-

Digitized by Google

drate. On these principles, therefore, the employment of pilocarpine can only be looked upon as uncalled for, and in not a few cases actually dangerous. He agreed with Dr. McKeough, that it may be very useful in early conditions of albuminuria, or even after convulsions have ceased, but not as a treatment of the eclamptic paroxysms. He would draw attention to a point often omitted in text-books, viz., that prodromata of convulsions—early uræmic symptoms—should always be looked for and actively treated. These consist most frequently in severe headache and repeated vomiting. They can often be completely relieved by narcotic treatment, and convulsions *prevented*, whereas depleting measures do little good, except assisted by the narcotic. As regards emptying the uterus, it has been his practice in a number of cases to treat by opium, etc., and take no step to hurry the confinement. He has never had reason to regret this course.

DR. GRANT agreed with Dr. Ross that it is important to watch puerperal cases, with a view to preventing the serious complication of convulsions. He trusts, in cases with slight œdema, to a course of potash, especially the bitartrate. He is in favor of the narcotic treatment of the actual eclampsia.

DR. DAVIDSON objected to the use of pilocarpine on account of the pulmonary dangers. He saw one case where great lividity was produced, with marked frothy exudation in the bronchi.

DR. THORBURN spoke of the value of pilocarpine in cases of generál anasarca, especially those of a more chronic kind. He considers its use in puerperal cases somewhat problematical. The treatment of puerperal convulsions, he thinks, should not be uniform, but must be based upon the nature of the probable exciting cause.

DR. MCKEOUGH, in reply, said he claimed no special value for the drug, but brought the cases before the Association as observations of some interest, and he was pleased with the discussion they had elicited. He thought his cases were all of uræmic origin, as such cases generally are.

DR. OSLER then read a paper on *The Clinical and Pathological Relation of the Cæcum and Appendix.*

DR. WHITEMAN, of Shakespeare, read a paper on *Pelvic Peritonitis and Pelvic Abscess.*

The following papers were read by title:

Retroversion of the Gravid Uterus, by Dr. W. B. Geikie, of Toronto.

Microörganisms in Puerperal Septicæmia, Prophylaxis and Treatment, by Dr. S. T. Johnson Alloway, of Montreal.

Field Hospitals and Climate in the Northwest Territory, by Dr. Nattreas, of Toronto.

Phlegmasia Dolens, by Dr. A. H. Wright, of Toronto.

Inebriety, a Disease the Result of Physical Causes, by Dr. Hepben Teft, of Guelph.

At the concluding general meeting the report of the Nominating Committee was received and adopted, and the following were elected

OFFICERS FOR THE ENSUING YEAR:

President-elect.—Dr. Holmes, of Chatham.

Vice-President for Ontario, Dr. Sloan, of Blyth; *for Quebec*, Dr. Colin Sewell, of Quebec; *for Nova Scotia*, Dr. Wickwire, of Halifax; *for New Brunswick*, Dr. Earle, of St. John; *for Manitoba*, Dr. Brett, of Winnipeg.

General Secretary.—Dr. James Stewart, of Montreal.

Treasurer.—Dr. Sheard, of Toronto.

Quebec was chosen as the *next place of meeting.*

The Association then adjourned.

AMERICAN GYNECOLOGICAL SOCIETY.

Tenth Annual Meeting held at Washington, September 22, 23, and 24, 1885.

(Specially reported for THE MEDICAL NEWS.)

(Concluded from page 361.)

WEDNESDAY, SEPTEMBER 23D.—SECOND DAY.

MORNING SESSION.

THE PRESIDENT, DR. WM. A. HOWARD, of Baltimore, read the Annual Address. It was entitled

TWO RARE CASES IN ABDOMINAL SURGERY.

He held that all cases, whether successful or not, should be put on record, in order that the knowledge of such affections might be increased. The paper described two rare cases of exceptional interest, in which the doctor was completely baffled in the diagnosis, and declined to make one.

Case I.—S. H., negress, aged 24 years, married, presented herself at the Dispensary of the University of Maryland April 20, 1882. She was seen by the clinical assistant and the following notes made: Menstruation appeared at the age of fourteen and had been regular and normal. She was the mother of five children, the youngest of whom was two months old. She had never had a miscarriage. Some days after delivery she noticed an enlargement in the lower portion of the abdomen, which gradually extended in the middle line until it reached the umbilicus, and was attended with bearing-down pains and frequent micturition. On examination, fluctuation was well marked all over the abdomen, with decided resonance about the umbilicus. There was dulness on percussion and bulging in both flanks. Six weeks later she returned to the dispensary, and at this time the resonance at the umbilicus had disappeared and the umbilicus projected. I saw her for the first time two weeks after this observation was made. At this time she was quite sick, the temperature being 102° F., the pulse 132, and the respiration 32 per minute. Examination showed the presence of fluid in the pleural sac. There were also some crackling râles heard through the lung. The abdomen was as large as at seven months' pregnancy, and was remarkably protuberant in the centre. There was complete dulness over the entire abdomen, not changed by change of position. There was no evidence of a solid tumor, but it had every appearance of a simple unilocular cyst. Vaginal examination showed the uterus well in front of the tumor, and the sound gave a measurement of two and three-fourths inches.

The question which arose was as to the nature of this tumor. Was it ovarian? The extreme infrequency of ovarian tumors in the negro race was against this view. The rapid growth of the tumor was also opposed to this view. The next affection considered was fibro-cystic tumor of the uterus, this is exceedingly rare. The speaker had seen but one such case in the negro. In

Digitized by Google

that case the cyst was filled with pus. The patient was operated upon, with a fatal result. Such tumors are rare before the age of thirty-six. They usually develop slowly. There was no menstrual disturbance in this case. For these reasons fibro-cystic tumor was excluded.

Was it a parovarian cyst? These usually develop even more slowly than ovarian cysts. They are usually flaccid. They contain a thin liquid, are comparatively rare, and do not affect the general health. This was therefore excluded.

It was certainly not a case of simple ascites, but was it a case of encysted dropsy, so called, of the peritoneum resulting from simple peritonitis? This is an extremely rare affection, and in the early stages there are symptoms of constitutional disturbance, the abdomen is not prominent, and often it is flaccid. Encysted dropsy was excluded.

Finally, on June 20th, I aspirated the cyst under antiseptic precautions. The fluid which escaped was of a light straw color, and coagulated as speedily as blood. After aspiration, large masses were readily felt through the abdominal wall. The character of the fluid corresponded with that which is said to characterize fibro-cystic tumors of the uterus. The speaker had, however, seen other cases which showed that the character of the fluid was not pathognomonic. In one case of abdominal tumor, fluid was removed which did not coagulate even after being kept for many days. The abdomen was subsequently opened and a fibro-cystic tumor found. In a case of supposed ascites in a man, aspiration was performed, and the fluid removed coagulated quite rapidly.

After the cyst was aspirated, the patient did well for three days, when acute peritonitis supervened, and the patient died on the seventh day.

At the autopsy, a mass as large as a child's head was found in the abdomen. This consisted of omentum, the transverse colon, and small intestine bound together by inflammatory exudation. The inflamed peritoneum was invaded everywhere with miliary tubercles, there was no ovarian or uterine disease. There was some tubercular ulceration of the small intestine, the other abdominal organs were not affected. The pleura was also invaded with scattered miliary tubercles. In both lungs there were some tubercles.

This then was a case of encysted tubercular peritonitis simulating ovarian or parovarian cyst. The failure to recognize the true condition was ascribed to want of attention to the previous history of the case and the recognition of the fact that there had been free fluid in the peritoneal cavity at the first visit.

He then referred to the few similar cases which had been reported. In these cases the disease had appeared, as a rule, under the age of twenty-five years. It has progressed rapidly, the length of time varying from six week to eight months.

Case II.—F. R., aged 24, was admitted to the hospital in July, 1883. She claimed to belong to the colored race, but looked much like a white woman. She had been married one year, but had never been pregnant. There was no evidence of uterine disease. The abdomen was much enlarged, measuring forty-seven inches just below the umbilicus. Vaginal examination showed the uterus pushed forward by a sac containing fluid. There was, apparently, an immense unilocular sac. This had been first noticed seven or eight years before. The increase in size had been gradual, and unaccompanied with pain.

As to diagnosis, ascites was dismissed both by the physical signs and the absence of any cause to account for such a condition. The length of time which the affection had lasted was against its ovarian origin. There are, however, exceptional cases in which an ovarian tumor may be present for a number of years, even as many as twenty-four, without requiring operation. The age of the patient, the length of time which the cyst had been present, the marked fluctuation, and the flaccid nature of the tumor, were in favor of a parovarian cyst. There was one point against this diagnosis, and that was that although the cyst was flaccid, it could not be compressed below the umbilicus. Fibro-cystic tumor was readily excluded. The history of the case was against the existence of encysted peritonitis. The balance of evidence seemed to be in favor of an ovarian or parovarian cyst.

On July 13, the operation was performed. It was made largely with the view of exploration. The peritoneum was found much thickened, and closely adherent to the sac. With difficulty the adhesions were separated for a short distance, and the cyst presented the appearance of an ovarian cyst. A trocar was introduced, and forty pounds of a greenish, viscid fluid removed. An endeavor was made to enucleate the cyst, but the adhesions were so extensive that this could not be accomplished. The cyst was then incised to the extent of the abdominal opening, and on looking into it, it appeared to occupy the whole abdominal cavity, stretching tightly over the spinal column. A small portion of the wall of the cyst was removed, a drainage tube introduced, and the opening closed with stitches. Peritonitis ensued and the patient died. A post-mortem was made, but owing to the physician's unavoidable absence, was not sufficiently full to throw any more light upon the case than had been obtained at the operation. The nature of the cyst, therefore, remained unsettled.

DR. EMMET, of New York, said a few words in regard to the difficulties of diagnosis. It seemed to him that the older he gets, and the more experience he has, the more uncertain he is about diagnosis. While in yesterday's discussion he did not favor opening the abdomen, yet, when a woman has an abdominal tumor he favors opening the abdomen to make the diagnosis, because she has something which must come out. As regards rapidity of development, we cannot depend on that. He has seen parovarian cysts develop in six weeks, and recover after operation. He has also seen cases which had lasted twenty-three years. He has twice opened the abdomen expecting to find an ovarian cyst, and found a fibro-cyst. About two years ago he saw a case in which he could not make a diagnosis. The abdomen was opened, and he saw just such a cavity as had been described. It seemed as if a cyst had at some time ruptured, and its contents had become encysted. The cavity was left open, frequently washing it out. In six weeks the cavity had greatly diminished. Unfortunately, the patient died at this time from strangulation of the small intestine. There is no set of symptoms which we can say belong exclusively to a certain condition.

DR. WILLIAM GOODELL, of Philadelphia, said that

Digitized by Google

the President seemed to have been somewhat ashamed that he did not make the diagnosis in the first case. He could tell him that he has removed tumors the nature of which he does not know to this day. In one case he worked for forty-five minutes before he found out what the tumor was. It turned out to be two ovarian tumors which had coalesced, including the uterus between them. He felt more and more the necessity of performing the exploratory operation. For it is impossible to make a correct diagnosis in many of these cases. To illustrate the difficulties of diagnosis, he reported a case which he saw some time ago. A lady presented herself with a solid tumor of the abdomen. There were also metrorrhagia and menorrhagia. He diagnosticated a fibroid tumor of the uterus, but the growth was so mobile as to suggest the possibility of a fibroid tumor of the ovary, and he so noted it in his record book. He advised against an operation. The lady went North, and her sufferings became so great that she consulted a distinguished gynecologist, desiring an operation. He wrote to him, asking his diagnosis. He told him what he thought of the case. He performed the operation, removing a large fibroid of the ovary, there being no adhesions.

Dr. T. A. Reamy wished to put on record another case in which a fatal result followed aspiration in tubercular peritonitis. The patient was a man, but the tumor presented all the characteristics of an ovarian cyst. The patient died the second day after the removal of the fluid.

There is great difficulty in the diagnosis of these abdominal tumors. In reference to the coagulability of fluid from other sources than fibro-cystic tumors of the uterus, he wished to say a word. In a case which he saw some years ago, he tapped a woman and obtained a large quantity of pure blood. This coagulated at once. The patient recovered, and is still living. His inference is that this was a case of tumor of the omentum.

Dr. Howard said, in closing the discussion, that it is agreed by all that cases often occur in which the diagnosis cannot be accurately determined, but in the majority of cases he thinks a correct diagnosis is made. The fact that he was able in these cases to eliminate so many of the ordinary conditions which give rise to these tumors, shows that we have the means of making the diagnosis. The object of the paper was to give an accurate account of this case, in order that it might assist others in cases of obscure abdominal tumors.

Thaddeus A. Reamy, of Cincinnati, then read a paper on

THE CARE OF THE PERINEUM DURING LABOR.

He referred to the various opinions which had been expressed on this subject. There is a general agreement as to the importance of preserving the perineum. In certain cases, however, from anatomical and pathological conditions, laceration is almost inevitable. He spoke of the various methods which had been proposed, dividing them into two general classes, those which aimed to support the perineum and those which were used with the object of retarding the progress of the head. There is one class, numerically small, who believe that the perineum should be let alone. The method about to be described he had adopted several years ago, and it had given him much satisfaction. He was persuaded that he had saved many perinea through its use. It was recommended for primiparæ and others where the structures were greatly imperilled. During the early part of the second stage the patient is allowed to assume any position she prefers, but when the head begins to distend the perineum, the patient is placed across the bed with the limbs in the lithotomy position, with the exception that the knees are kept close together. This is important. The limbs are held in this position by two assistants. A piece of muslin or a towel, ten inches wide, and forty or fifty inches long, is carried around the buttocks of the patient and over the hemisphere produced by the bulging perineum with the upper edge on a level with the fourchette, and the ends given to the assistants. They are instructed to make traction, during the pain, in the manner that the accoucheur may direct. The bandage must be applied smoothly. The direction of the force may be made in any required direction. Care must, however, be taken that the pressure is equably distributed, and that the assistants do not simply pull on the middle or posterior part of the bandage, while the anterior portion is left lax.

In order to show that this procedure is based on good anatomical grounds, the speaker next referred to the anatomy of the perineum, illustrating his remarks with diagrams. According to the old descriptions of the anatomy of this region it was considered that the muscular fibres decussated in the part between the vagina and rectum. Recent observations show that this is not the case, but that the fibres simply meet, and a laceration of the perineum divides no muscular fibres transversely, with the exception of those of the transverse perinei. The fibres are simply separated. When the sphincter ani is divided, its fibres are, of course, divided transversely. The perineum is prevented from lacerating by the protection afforded by the tissue below and the integument. The bandage used in the way described affords a supplementary perineum, as it were. By keeping the limbs in the position indicated, nature is able to supply tissue for the relaxation of the perineum. When the perineum is bulged the lateral and posterior sulci disappear, and the perineum with the advancing head forms almost a hemisphere. The towel is in contact with every part of this hemisphere. The advance of the head may be retarded by making traction on the towel. Where it is accessible, a narrow bed may be used with advantage, the assistants taking their positions near the head of the patient.

The use of this bandage avoids any tendency to exciting expulsive efforts from reflex irritation of the perineum, as is sometimes seen where the fingers are used. It is comfortable to the patient, and does not cause more exposure than other methods. The bandage may be kept on until the shoulder is delivered, thus avoiding rupture from this cause. In order that this method shall be successful, it is important that every detail shall be carried out with painstaking care.

Should a rupture occur, the immediate operation should be resorted to.

Afternoon Session.

Dr. Wilson, of Baltimore, said that all authorities agree that the perineum should be supported, but there is a great variety as to the way in which this support

Digitized by Google

should be made. Dr. Reamy's method appears to be very practical, and it has the advantage of leaving the operator free to watch the case.

with decided advantage to the patient. He had, therefore, modified his views. A detailed account of the nine cases in which the forceps had been used was then given. The instrument used had been Dr. Howard's modification of Tarnier's forceps.

DR. NEALE, of Baltimore, exhibited his modification of the Tarnier forceps, which consisted in adapting the Tarnier principle to the Simpson forceps.

DR. MANN said he had used the Tarnier forceps for the past two years in a number of cases, with, in the main, satisfactory results. In one case he had a little misfortune which might not have happened with other forceps. It was a case of deformed pelvis in which the Tarnier forceps were applied. The child was finally delivered and the woman made a good recovery. The child was, however, injured by the forceps. The outer edge of one orbit had been crushed in, destroying the eye. The child was living at the time of birth, but subsequently died.

THE PRESIDENT said that, so far as he knew, he was the first one to use the Tarnier forceps successfully in America. He thought that in cases of occipito-posterior positions, the application of other forceps interferes with the rotation of the head, but with the Tarnier forceps the head is free to rotate.

EVENING SESSION.

At the business meeting, the following were elected

OFFICERS FOR THE ENSUING YEAR:

President.—Dr. Thaddeus A. Reamy, of Cincinnati.

Vice-Presidents.—Dr. Theophilus Parvin, of Philadelphia, and Dr. George J. Engelmann, of St. Louis.

Secretary.—Dr. Joseph Taber Johnson, of Washington, D. C.

Treasurer.—Dr. Matthew D. Mann, of Buffalo.

Other Members of the Council.—Drs. Frank P. Foster, B. B. Browne, J. C. Reeve, and R. B. Maury.

New members were elected as follows: Dr. J. B. Hunter, of New York; Dr. Charles Jewett, of Brooklyn; and Dr. W. H. Parish, of Philadelphia.

The *next meeting* will be held at Baltimore, Md., September 21, 22, 23, 1886.

THURSDAY, SEPTEMBER 24TH.

MORNING SESSION.

DR. R. STANSBURY SUTTON, of Pittsburg, read a paper on

A MODIFICATION OF EMMET'S CERVIX OPERATION IN CERTAIN CASES, WITH A CASE.

He stated that, while the operation was original as far as he was concerned, he did not claim to be the only one who had performed it. Cicatricial tissue is found to a greater or less extent in every lacerated cervix which has lasted for any length of time. This is especially apt to be the case where nitrate of silver has been used in the treatment of the cervix. The hardened tissue may be present in both lips or it may be limited to one lip.

The case reported was operated on June 5, 1885. She was the mother of several children. There was a double laceration of the cervix. The tissue of the anterior lip was hardened and hypertrophied, and the lip was convex from side to side and also from before backward, so that, by the ordinary method of operation, correct coaptation could not be effected. The tissue of the anterior lip was as hard as cartilage. Ordinary denudation of the posterior lip was sufficient, and this was made, leaving the strip of mucous membrane somewhat wider than usual. The cicatricial mass involving the anterior lip was removed from border to border, completely denuding this portion of the cervix. The parts were then brought together in the usual way, and the result was excellent. The cervical canal readily admits a sound and the woman menstruates without difficulty.

He thought that there were cases in which nothing short of the complete removal of the cicatricial tissue will be sufficient.

DR. WM. GOODELL, of Philadelphia, said that he had resorted to this device on more than one occasion. He had done another thing on a few occasions. He had outlined the strip of mucous membrane to be left and dissected it from the tissues below, leaving it united at its base. The indurated tissue has then been removed and the flaps brought together. The result has been good. He had never as yet denuded both surfaces, although he understands that it has been done by some of the gentlemen.

There is a point on which he should like to hear the opinion of the Society. Sometimes the Nabothian glands are enlarged and are cut through in the operation, and it has been his rule to dissect these out, but sometimes this leaves an attenuated cervix. He should like to hear what the members have to say as to the method of dealing with these enlarged glands.

DR. SKENE, of Brooklyn, said that the term cicatricial tissue is incorrect. This is not cicatricial tissue. How could there be cicatricial tissue below a mucous membrane where there has been no damage? It is a true sclerosis, a hypertrophied, indurated tissue. This is, however, simply a question as to name. Much can be done to get rid of this tissue by preparatory treatment. But this often requires too much time, and then such an operation as that proposed by Dr. Sutton comes in. While speaking of preparatory treatment, he would say that enlarged Nabothian glands should be disposed of either by preparatory treatment or at the time of the operation. His plan in the cases referred to by Dr. Sutton has been to do a preliminary operation, which consists in removing a transverse, wedge-shaped piece out of one or both lips of the cervix, as the case may require, and then bringing the surfaces together with silk stitches. After the first day the patient can go about, and the sutures are removed in the course of a week or ten days. After the size of the cervix is reduced he performs the ordinary operation. He has done both operations at one sitting, but he prefers to do them separately. One objection to the method of Dr. Sutton is, that it leaves cicatricial tissue.

DR. GEORGE J. ENGELMANN, of St. Louis, has found the condition referred to very constantly. He now cuts deeply and removes the indurated tissue; and in old and severe cases it is impossible to retain the strip of mucous membrane. He, therefore, removes it. He has done this on both lips, and on some occasions has had complete union, but the passage of a probe serves to keep a canal open. For the last few years he has paid no attention whatsoever to this central strip. He

Digitized by Google

now inserts a single strip of the carbolized silk thread which he uses in closing the opening. A probe passed a few times after the removal of the sutures will dilate the opening. The result of this operation has been good. The union, the involution, and the restoration of the health of the patient have been perfect. This operation has been done only in severe cases, and, as far as I know, none of these patients have conceived.

DR. M. D. MANN has tried the method described by Dr. Sutton. In only one case was it necessary to denude both surfaces. To keep a patulous canal, he introduced a piece of small drainage-tube. The case did well. Where there are diseased Nabothian glands, and there is plenty of time, he prefers to treat the mucous membrane before performing the operation. Where there is little time, he excises the follicles. So far, the result has been good. He has, however, never done this on both lips.

DR. BAKER, of Boston, thought that the retention of the mucous membrane is important, and that the method of Dr. Sutton, by leaving cicatricial tissue on one side of the canal, will tend to make the canal tortuous. As a rule, if the patient is properly prepared, it will not be necessary to remove this hypertrophied tissue. If this is not done, Emmet's operation can still be performed in the way described by Dr. Skene. He, however, prefers to do both operations at the same time. It is then not necessary to introduce a suture to bring the transverse incision together. Great care should be exercised in the introduction of substances between the two flaps.

THE PRESIDENT, DR. HOWARD, of Baltimore, said that, a few weeks before the death of Dr. Sims, he saw Dr. Harry Sims perform this operation in the presence of his father. He inserted a glass tube which fitted so loosely that it had to be retained with a plug of cotton.

DR. SKENE thought that, if the denudation was practised on both sides, stenosis would certainly follow.

DR. WILLIAM GOODELL, of Philadelphia, then read a paper on

INFLAMMATION OF THE PAROTID GLANDS FOLLOWING OPERATIONS ON THE FEMALE GENITAL ORGANS.

He referred first to the close relation existing between the salivary glands and the genital organs of the adult as shown in mumps and other conditions. Parotid bubo seems particularly liable to follow ovariotomy where septicæmia has taken place. He had seen parotid bubo once in 153 cases of ovariotomy. This was in a greatly emaciated woman, from whom a tumor weighing eighty pounds was removed. The patient had been twice tapped, once six weeks before the operation. The second tapping was followed by septic poison, and the operation was performed as a last resort. The patient did well until the ninth day, when the left parotid gland began to swell. It suppurated and was opened. The patient finally died on the twenty-second day after the operation.

There is a transferrence of irritation to the parotid glands in which there is no evidence of septic poisoning. Of this the author had seen three instances: twice after ovariotomy and once after oöphorectomy. In these cases the parotid complication did not influence the progress of the case. Not one of these ended fatally. He regarded the affection of the glands as sympathetic, and not symptomatic.

Within a short time he had operated on a lacerated cervix. The operation was followed by free hemorrhage, and in the second week the parotid glands began to swell. This was succeeded by hysterical trismus which lasted for some time. The patient recovered.

DR. SUTTON said that, out of twelve ovariotomies, he had lost one patient, and she died with the complication referred to in the paper. The case did well until convalescence was reached, when one parotid gland began to swell. This was followed by swelling of the other gland. The temperature varied one or two degrees from the normal. There was slight diarrhœa, no tympany, and no soreness. A number of rose-colored spots were found about the second week over the abdomen and arm. In the third week she became much worse. The glands diminished in size, but the temperature ran up and she died. He regarded the case as septicæmic. Others who saw the case considered it a a well-marked instance of typhoid fever.

DR. J. T. CHAS. JOHNSON had seen this complication in one case of ovariotomy. On the third or fourth day, swelling of the parotid appeared. There were the rose-colored spots referred to by Dr. Sutton. There was some fever, and the patient died on the sixth day.

DR. MANN referred to three cases which he had seen. The first was a case of ovariotomy. There were distinct symptoms of septicæmia, and the patient died before the glands suppurated. The second case was one in which he removed all the uterus above the internal os, and also the ovaries. At the end of the first week, one gland became swollen. There was little fever. The patient made a good recovery. The third case was a boy who had received a penetrating wound of the abdomen. Enlargement of the glands followed, but he made a good recovery.

DR. EMMET added his experience of two cases. Once it followed an operation for lacerated cervix, the patient recovering. Once it followed an operation on a small vesico-vaginal fistula, the patient dying. This is the only time he has seen death follow this operation.

DR. BAKER had had the complication follow Tait's operation, but the patient recovered.

DR. REAMY had had two cases. One was after Tait's operation. The glands did not suppurate, but the patient died the seventh day after operation. The second was a case of supravaginal hysterectomy, in which the uterus and both ovaries were removed. The left gland became much enlarged, but did not suppurate. The patient recovered.

DR. JAMES R. CHADWICK, of Boston, then read a paper on

PERISTALSIS OF THE GENITAL TRACT, AND A NEW THEORY TO EXPLAIN RELAXATION OF THE VAGINAL OUTLET DURING LABOR.

Some time ago he was called to see a primipara in labor. He found the os slightly dilated and the vaginal outlet quite rigid. Returning two hours later, the outlet was found much relaxed, although the head had not escaped from the uterus. On another occasion, a woman with a bleeding fibroid tumor consulted him. The examination revealed quite a small outlet. Ergot was given to check the bleeding. Later the patient returned

Digitized by Google

and the outlet was found much relaxed. This had occurred coincident with the occurrence of uterine contractions, and the forcing down of the tumor. Further investigation of this subject had led him to the conclusion that there is a peristaltic action of the lower portion of the genital canal, as well as of the Fallopian tubes, and that it is to this that the relaxation of the outlet is largely due.

DR. GOODELL said that a fact which seems to bear out this idea is, that when after labor or an abortion a piece of membrane or of placenta is retained, the cavity of the cervix is found funnel-shaped, showing that the uterus is trying to force out the retained substance.

DR. THEOPHILUS PARVIN, of Philadelphia, reported a case of

FACIAL PARALYSIS IN THE INFANT FROM THE USE OF THE OBSTETRIC FORCEPS.

The case was a well-proportioned woman, aged 30 years, who had been in labor thirty-two hours, the first stage lasting twenty-four hours. The only difficulty appeared to be want of strength in the uterine contractions. The forceps were, therefore, applied, and the child delivered. The following day it was observed that one side of the face was paralyzed, this was especially noticeable when the child cried. There was no evidence of bruising from the forceps. The paralysis disappeared in ten days without treatment.

The literature of this affection was then referred to, and the reported cases given. The writer referred to cases of spontaneous facial paralysis occurring in labor, and pointed out the means of distinguishing between this palsy and that caused by the forceps.

In one case that has been reported, there was double facial palsy caused by the forceps, but usually it is only one side that is affected. So far as statistics permit a conclusion, the side affected is that which is towards the posterior portion of the pelvis. Thus in a vertex presentation, and left occipito-anterior position, the palsy will be of the left facial nerve. The explanation of this is probably found in a lateral obliquity of the fœtal head, and indicates that the parallelism of the fœtal head planes and the maternal pelvic planes is not as constantly present as some obstetric teachers have asserted.

While spontaneous recovery is the rule in facial palsy caused by the forceps, this does not always occur, and the palsy remains permanent. Therefore, if recovery has not taken place in one or two months after birth, appropriate treatment should be begun.

DR. ELWOOD WILSON, of Philadelphia, had seen this accident a number of times, both in his own practice and that of others. Recovery, as a rule, has occurred spontaneously.

DR. GOODELL had seen such cases, and in every instance the paralysis has been on the right side. He attributes this to the predominance of the left occipito-anterior and the right occipito-posterior positions. Under such circumstances, one blade of the forceps would make pressure on the nerve.

DR. SKENE said that differential diagnosis between facial paralysis from injury and facial paralysis from apoplexy is of importance, for apoplexy is not uncommon in newborn children. Usually the diagnosis is readily made, but difficulty occurs where there is facial paralysis from injury associated with paralysis of the arm caused by violence in delivery. He recently saw such a case in consultation. In this case it was of great importance to complete the labor quickly, and the shoulder had been injured in delivery, so that there was facial paralysis and paralysis of the arm on the same side. At first there was no trace of contusion, but in a short time ecchymosis appeared and a favorable prognosis was given, which was verified.

DR. RICHARDSON, of Boston, said that in most of the cases that he had seen the paralysis had been on the right side. He had seen it occur once from the pressure of a bony tumor of the pelvis. He had seen it where the forceps were applied to the after-coming head.

DR. PARVIN, in concluding the discussion, said that so far as positive statements were made by those discussing the paper, they confirmed the statement he had made as probable, that the side of the face affected by palsy from the forceps was the posterior. The only other point to which he desired to refer was to emphasize the fact, that this palsy, though usually a simple thing, disappearing in a few weeks, in some cases is permanent, and therefore the importance of not being too positive in promising recovery.

The following papers were read by title:

The Genupectoral Posture in the Prolonged Nausea and Vomiting of Pregnancy, with Cases, by Dr. H. F. Campbell, of Augusta, Ga.

A Study of an Unusual Type of Puerperal Fever, by Dr. Fordyce Barker, of New York.

A RESOLUTION OF SYMPATHY.

A resolution expressing the sympathy of the Society with Dr. Albert H. Smith, in his sickness, was adopted.

The officers for the ensuing year were then installed, and the Society adjourned.

MEDICAL SOCIETY OF VIRGINIA.

Sixteenth Annual Session, held at Alleghany Springs, Montgomery Co., Sept. 15, 16, and 17, 1885.

(Specially reported for THE MEDICAL NEWS.)

(Continued from p. 356)

THURSDAY, SEPTEMBER 17TH.—THIRD DAY.

MORNING SESSION.

DR. R. T. STYLL, of Richmond, presented the

TREASURER'S REPORT,

showing a balance of $390.55.

A sum, not exceeding $100, was voted to be used, if necessary, to retain legal council in the event of the State Board of Medical Examiners being sued, as threatened by a complainant who did not pass examination.

DR. W. D. TURNER, of Fergusson's Wharf, from the Committee to consider the subject, reported favorably on the petition for the enactment of a bill to regulate

THE PRACTICE OF PHARMACY.

DR. BEDFORD BROWN, of Alexandria, read a paper on the

TREATMENT OF LACERATIONS OF THE OS AND CERVIX UTERI, WITHOUT SURGICAL OPERATION.

Emmet's operation, though valuable, is sometimes dangerous. An experience with about twenty cases

Digitized by Google

during the past eleven or twelve years convinces the author that this large class can be relieved by a simple, painless, safe, and easy method of treatment by any intelligent practitioner, without resort to surgical operation, and by means of local treatment alone. The character of his cases has varied from a mere fissure to the most severe laceration. Sterility was an invariable feature. Many cases were complicated with cellulitis, localized peritonitis, subinvolution, metrorrhagia, displacement, proctitis, etc. The general health was impaired in almost every case. There were peculiar neuralgic pains in all those nerves coming within the circle of sympathy of the exposed and lacerated nerves of the os uteri. Thus, the great lumbar plexus manifested its sympathies in the form of a constant aching pain in the base of the sacrum. Ovaralgia on the side of the injury, or on both sides, if the injury was double, was almost invariable. In a few cases the development of sciatica indicated reflex sensation on the part of the sciatic nerves. Neuralgia of the crural nerves and their branches was common. These pains extended to the patella, and even down to the dorsum of the foot.

Dr. Brown has healed, by first intention, several cases of laceration in the acute stage by means of absolute quiet, disinfection, and cleanliness. If lacerations fail to heal by first intention immediately after labor, they never heal spontaneously by second intention. Local treatment then becomes necessary. Dr. Brown examines the womb for lacerations, etc., immediately after the discharge of secundines in each case of labor; and, if found, he begins a systematic course of treatment after the first twenty-four hours, with a view to absolute disinfection and cleanliness. Warm douches of borax, boracic acid, and carbolic acid solutions are gently used two or three times daily, and the patient is kept in the recumbent position for two weeks. If healing does not occur by that time, it does not occur afterwards spontaneously. In eight or ten weeks later, in such cases, he proceeds to secure healing by the second intention. For this purpose he has used carbolic acid, chromic acid, Battey's solution of carbolic acid and iodine, Churchill's tincture of iodine, solid nitrate of silver, and even nitrate of mercury, but without favorable results. He then adopted graduated solutions of crystals of nitrate of silver, with excellent results. Solution No. 1 is as follows:

℞.—Argenti nitratis, cryst. . . . ʒss.
Aquæ destil. . . . . fʒj.—M.

This solution is to be applied to the interior of the cervical canal freely, down to the os internum, as the cervical canal is always involved in the rent and is left in a diseased condition.

Solution No. 2 is:

℞.—Argenti nitratis, cryst. . . . ℈iiss.
Aquæ destil. . . . . fʒj.—M.

This solution is to be applied with a camel's-hair brush freely over the entire external surface of the os and cervix, including the fissure of the laceration, until a uniform white coating is formed, thick and tenacious, almost resembling a coat of paint. This gives immediate protection to the super-sensitive extremities of the exposed nerves and tender granulations, and acts as a sedative application, which allays irritation, redness, inflammation and engorgement rapidly, and stimulates a new vital action and healthy growth of granulations, which fill up the fissures or cavities of the laceration, and accomplishes the healing of the wound by second intention. This coating, in the meantime, forms an impervious barrier to the further absorption of septic matter from the discharges, and in this way relieves pelvic cellulitis. The healing process and reduction of hypertrophy of the cervix and inflammation progress rapidly. The process of absorption is stimulated in a wonderful manner, and the process of involution is also promoted in proportion.

In simple fissure of the cervix extending through the mucous membrane and fibrous tissue only partially, solution No. 1 should be applied thoroughly in the groove of the fissure, so as to reach its very bottom, and thus induce healing from the lowest depths of the wound; otherwise the object will be defeated.

Solution No. 3 is:

℞.—Argenti nitratis, cryst. . . . ʒiss.
Aquæ destil. . . . . fʒj.—M.

This solution is only to be applied to the external surface of the cervix, in the event of hypertrophy and induration remaining after the lacerations have healed; otherwise, if left in that condition, it forms a basis for the renewal of inflammation and reopening of the wound. After treatment, the cervix becomes naturally soft and normal in dimensions. The os is not only not contracted by the application, but returns to a perfectly healthy condition.

A great majority of females thus treated have borne from one to three children since, and have been entirely free of all uterine troubles. In three patients—one having borne three children, the second two, and the third one child after treatment—the os uteri in each case was found perfect as to softness, dimensions, and freedom from disease. Concealed fissures are often found after labor in the mucous membrane of the cervical canal, and cause an infinite amount of local disease, such as endocervicitis, hypertrophy of the adjacent tissues, inflammation of the fibrous tissues of the cervix, leucorrhœa, and often painful menstruation. A favorite locality for these fissures is at the internal os. The mucous membrane and submucous tissue are split through, and then the rent remains a source of trouble for years. The No. 1 solution of nitrate of silver reaches these wounds admirably, and will surely heal them from the bottom.

DR. GEORGE T. HARRISON, of New York City, then read a paper on

PUERPERAL SEPTICÆMIA, ESPECIALLY WITH REGARD TO PROPHYLAXIS AND ETIOLOGY.

Without a wound somewhere along the genital tract, puerperal septicæmia does not exist. In the puerperal woman, the conditions for the rapid development of the pathogenous fungi are most favorable. Contrary to general opinion, Gusserow has shown that there is no connection between puerperal sepsis and erysipelas, and that the micrococci of erysipelas cannot produce pathological changes identical with septic processes. The pathogenous fungi affect the organism immediately, while putrefactive germs do so indirectly by

Digitized by Google

their influence on decomposable matters always present in puerperal women. An autogenous or autochthonous infection is an impossible thing. The characteristic features of non-pathogenous infection are, (1) the late appearance of the fever; (2) the slight participation of the general condition; and (3) the existence of local morbid substrata.

The principles of prophylactic treatment consist in pure air for the lying-in woman, the careful avoidance of introduction of infectious matters into the genital passages, and the thorough disinfection of the genital tract. The physician's and midwife's hands, instruments, etc., should be disinfected before using about a puerperal woman. During the pregnancy, especially if there be any puerperal fever epidemic, the woman should frequently wash her external genitals with soap and water, and afterwards with boracic acid solution.

In tedious and complicated labors, where frequent examinations have to be made, or instruments used, injections are strongly indicated. Sometimes putrefactive decomposition of the uterine secretions occurs before labor ends. In such cases, complete the labor as speedily as possible, and thoroughly disinfect the genital tract by intrauterine injections of carbolic acid or mercuric bichloride. Wash the external genitals three or four times daily, and disinfect once a day by carbolic acid or mercuric chloride solution. Close all lacerations of the perineum and vagina under strict antiseptic precautions, as the continuous catgut suture. Iodoform dusted over the raw surface favors union. A powerful contraction and retraction of the uterus greatly help in securing immunity from invasion of putrefactive bacteria; hence the value of Credé's method in expelling the placenta.

DR. H. GREY LATHAM, of Lynchburg, read the report on

ADVANCES IN SURGERY.

He said that laparotomy is now an established operation for strictures of the intestines, strangulations, excision of organs not essential to life, etc. Do not wait too long in strangulations of the bowels; operate as soon as diagnosis is made out—as soon as vomiting sets in. Cut down so as to reach the cæcum at once. If this is distended, the obstruction is below; if it be collapsed or not tense, it is above. If the strangulated coil of bowel is gangrenous, resect it, and establish an artificial anus. When laparotomy is rejected, adopt Nélaton's enterotomy in the right iliac fossa. He stated as propositions, (1) that the best guide to the seat of an obstruction is not manual exploration, but visual examination, assisted, if necessary, by extrusion of the bowel; and (2) that no case of operation is properly concluded until an overdistended bowel is relieved of its contents.

In operations for hernia, invagination has been laid aside or neglected, and obliteration of the sac or closing the neck are the popular procedures. In operative treatment for rectal cancer, the following guides are said to be reliable: 1. If the finger cannot be passed beyond the disease, unless it is confined to the posterior wall, do not operate. 2. The growth can be removed at a somewhat greater height when the disease is confined to the posterior wall. 3. If, when the finger has passed beyond the disease, the bowel is movable on the adjacent structures, generally speaking, the growth has not extended beyond the rectal walls, and the case is suitable for operation; but if the bowel feels hard, rigid, and firmly bound to the surrounding organs, the case is unfavorable for an operation. 4. Examine carefully the abdominal viscera, and if secondary deposits be suspected in the liver, no operation should be performed.

DR. RIVES TATUM, of Harrisburg, presented the report of the Committee on *Advances in the Practice of Medicine.*

(*To be concluded.*)

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

ITALIAN QUARANTINE.—The Italian bark Excelsior arrived here, a few days ago, from Marseilles, upon which when she was a few days out, a sailor died, of cholera. No other case followed. She now lies in the lower bay, and a rigid quarantine against her has been established.

THE FUTURE OF THE INTERNATIONAL CONGRESS excites little or no interest, and those who discuss the matter at all, uniformly express hope that the nation may be spared the disgrace of a slipshod meeting, where junketing shall be made to fill up the gaps caused by the withdrawal of the valuable scientific work which, under the original organization, was to have been contributed by the best men from all parts of the country.

MR. JOHN MCCULLOUGH, the tragedian, who is now an inmate of Bloomingdale Asylum, is the victim of general paresis, and, from all accounts, the disease in his case is rapidly progressive. This is one of the examples that show the necessity for prompt asylum treatment; and, had the wiser counsels of his physicians prevailed, not only much misery, but a great deal of the money he squandered might have been saved. In no city of the Union do we find the stupid obstinacy of juries and popular ignorance regarding the treatment of the insane that prevail in New York. Rhinelander, who was discharged as sane, has been on the rampage since he obtained his freedom; and the last act of Prouse Cooper, the tailor, before going to Australia, was the purchase of six or eight pistols.

MORE RESIGNATIONS FROM THE CONGRESS ORGANIZATION.—Dr. William H. Welch, of Johns Hopkins University, has declined the Secretaryship of the Section of Pathology; Drs. T. A. McGraw, of Detroit, and J. R. Weist, of Richmond, Indiana, have declined Councillorships in the Section of Surgery; Dr. E. H. Hazen, of Davenport, Iowa, has declined the Councillorship in the Section of Otology; and Dr. E. L. Shurley, of Detroit, Mich., the Councillorship in the Section of Laryngology.

PUBLIC OPINION ON THE CONGRESS ORGANIZATION.—The committee has doubtless done just the work its manipulators set to its hands; but, whether its policy be voted wise or foolish, the denouement will show that the breach between the opposing parties is widened beyond

Digitized by Google

repair, and that the contending voices are dissonant beyond the hope of harmony.

The distinguished guests who, soon after the June house-warming, stepped out and have since been standing in the rain, have not been asked to come in by the new proprietors; nor would they in the existing state of the house have accepted the invitation had it been extended. Their places have been or soon will be filled by others, worthy, indeed, but less renowned; and when the new list of officers and councilmen for the Ninth International Medical Congress shall be laid before the medical world, it will be destitute of many attractive features which characterized the original committee's issue in the early spring. Whether or not this strangely altered face will have charms of sufficient attractiveness to draw our foreign brethren across the sea remains to be seen; but if the signs of the times be not grossly misleading, the Congress of 1887 will not meet on American soil.—*Louisville Medical News.*

ASSOCIATION OF AMERICAN INSTITUTIONS FOR IDIOTIC AND FEEBLE-MINDED PERSONS will hold its ninth annual session at the Illinois Asylum for Feeble-minded Children, Lincoln, Ill., commencing Tuesday, October 6th, at 3 o'clock P. M.

Papers will be presented by Col. H. M. Greene, Dr. F. C. Carson, Dr. H. B. Brown, and others.

By resolutions of previous sessions, the following reports will be called for: "On Causation of Idiocy, etc.;" "On Status of the Work before the People and Legislatures of the Various States;" "On Development and Progress of the Institutions Represented;" "Improvements in School Training and Hospital Care Introduced during the Past Year;" "Clinical Reports of Special Cases."

CHOLERA IN SPAIN.—According to the reports received by the National Board of Health, there have been, from March 4 to August 16, 159,173 cases and 63,640 deaths.

THE NESTOR OF PHYSICIANS IN THIS COUNTRY is probably Dr. Neyron, Professor of Anatomy in Notre-Dame University, Indiana. He is ninety-four years of age, and was a surgeon in Napoleon's army during the Russian campaign, and was present at Waterloo. After the restoration he became a Catholic priest, and was an early missionary in the Northwest. Few men of seventy are so strong and active, and he is still able to conduct his classes.

DR. PAUL BÖRNER, Editor of the *Deutsche medicinische Wochenschrift*, and Editor and Publisher of the *Jahrbuch der Prakt. Medicin*, died recently in Berlin after a short illness, at the age of fifty-six years.

THE ANTWERP MEDICAL CONGRESS.—This Congress terminated its labors on the 30th of August, by a visit to the Hospital of the Stivenberg. In the full sittings it was resolved that "in the present state of relations between the peoples of Central Europe, land quarantines and sanitary cordons are useless and even dangerous measures; the fumigation of letters is useless." The majority of the Congress declared itself for the maintenance of maritime quarantines in seaports and at the mouths of rivers. Such quarantines were also pronounced to be feasible and efficacious in Belgium.—*Lancet*, September 5, 1885.

NOTES AND QUERIES.

DEATH OF DR. ANDREW MURPHY.

AT a meeting of the physicians of Parkesburg, Chester County, Pennsylvania, the following preamble and resolutions were adopted:

Whereas, God in his Providence has removed from our companionship and counsel, Dr. Andrew Murphy, who for over half a century has honored and graced the ranks of the medical profession, therefore,

Resolved, that while we bow in submission to the decree of an all-wise Father, we wish to record our appreciation of the example which his life of generous and noble deeds affords, and our confident trust that through the blessed atonement, he has only been "called up higher" to a more exalted sphere of action, making the loss which the profession, the community, and his family have sustained, his infinite gain.

Resolved, that we hereby bear cordial testimony to the unvarying courtesy which ever characterized his relations with the profession, and to the esteem and regard in which he was universally held by its members.

Resolved, that a copy of these resolutions be presented to the family, with an expression of our sympathies, and be published in THE MEDICAL NEWS, the county papers, and *Medical and Surgical Reporter* of Philadelphia

(Signed.) DR. EBER HUSTON,
DR. T. A. TAYLOR,
DR. E. V. SWING,
Committee.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING SEPTEMBER 26, 1885.

DUGAN, J. S., *Medical Director.*—Waiting orders.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 22 TO SEPTEMBER 28, 1885.

PROMOTIONS.

MCPARLIN, T. A., *Lieutenant-Colonel and Assistant Medical Purveyor*, to be Surgeon with rank of Colonel, to date from September 16, 1885.

IRWIN, B. J. D., *Major and Surgeon*, to be Assistant Medical Purveyor with rank of Lieutenant-Colonel, to date from September 16, 1885.

POPE, B. F., *Captain and Assistant Surgeon* with rank of Major, to date from September 16, 1885.

APPOINTMENT.

MORRIS, EDWARD R., to be Assistant Surgeon with rank of First Lieutenant, to date from September 17, 1885.

ADAIR, G. W. *Captain and Assistant Surgeon.*—Granted leave of absence for one month with permission to apply for one month's extension.—*S. O. 104, Department of Dakota*, September 18, 1885.

BUCKNELL, GEORGE E., *First Lieutenant and Assistant Surgeon.*—Ordered from Department of Dakota to Department of the East.—*S. O. 219, A. G. O.*, September 24, 1885.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING SEPTEMBER 26, 1885.

AUSTIN, H. W., *Surgeon.*—To proceed to Burlington, Vermont, on special duty, September 23, 1885.

THE MEDICAL NEWS will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

AORTIC INCOMPETENCE.

A Clinical Lecture Delivered at the University Hospital.

BY I. E. ATKINSON, M.D.,

PROFESSOR OF PATHOLOGY, DERMATOLOGY, AND CLINICAL MEDICINE IN THE UNIVERSITY OF MARYLAND.

GENTLEMEN: We are fortunate to-day in having an opportunity to compare four cases of valvular disease of the heart, with consequent and associated conditions of the highest interest.

Case I.—Our first patient is a mulatto, 45 years old, a brickmaker. He has never had syphilis or rheumatism. He has been generally healthy, but has led a life of hardships, though not of excess. His personal and family history is not noteworthy. About two years ago he began to have pain in his chest, and to suffer from palpitations, and gradually lost the energy and endurance requisite for his work. He has never had dropsy. He is, as you see, of small but muscular frame. His expression is anxious. As he stands before you, his naked body is seen to vibrate with every beat of his heart. Violent pulsation is visible over his subclavian, carotid, temporal, brachial, and radial arteries. The brachial fairly writhes and leaps from its bed. Bulging in the præcordial region is manifest. The head of the right clavicle is distinctly enlarged, but it is equally evident that this is due to accidental causes, and not to growth or pressure from within. A heaving pulsation is felt over the whole anterior chest wall. The hand laid flat over the second and first intercostal spaces, to the right of the sternum, perceives a feeble systolic thrill but no shock. The area of cardiac dulness extends nearly one inch beyond the nipple line, and the apex beat is strongest in the sixth interspace. It is forcible and diffused. There is slightly increased relative dulness over the upper sternal region. A double murmur is heard over the apex, but as the ear is moved towards the axillary line, the mitral valve is heard to close perfectly. Superiorly, the double blowing murmur becomes more and more intense and is most distinct in the second right interspace at the sternal border. These murmurs are audible over the whole right upper chest, and to the left no normal valve sound can be heard until the axillary line is reached. They are loud and prolonged. In the left interscapular region both the systolic and diastolic murmurs are heard as low as the angle of the scapula. They are pronounced over both carotids, and are audible over the abdominal aorta, and the femoral arteries.

The radial pulse strikes the finger with an abrupt, powerful shock, that, however, exhausts itself at once, and reveals typically the "water-hammer" or "Corrigan's" pulse, characteristic of insufficiency of the aortic valve. Similar pulsatile violence is observed in the femorals, which beat synchronously with the radials. If the finger is pressed behind the suprasternal notch, the pulsation, so apparent to the eye, is felt to be of a violent expansile character. This arterial distention is also very evident when the fingers are placed over the carotids. There is no pulmonary disorder, no cough, no dysphonia, no dysphagia. There is much pain under the sternum. It is paroxysmal and frequently extends to the left shoulder and down the arm. The pupils are equal. There are no signs of intrathoracic pressure; in a word, aneurism is not present. The abdominal organs are sound. There is no albuminuria. Sleep is uninterrupted, but is often accompanied by dreams. He suffers sometimes from dyspnœa, but it is not oppressive, and you observe how easily he rests in a supine position. In such a case a diagnosis can almost be made from viewing the præcordial prominence, the forcible heart action, and the violent pulsation of the larger superficial arteries. We have to do, indeed, with aortic regurgitation with consequent great hypertrophy of the left ventricle with dilatation, and also with dilatation of the aorta and of the great arteries nearest to it. Whether the loud systolic murmur and thrill are due to aortic stenosis, or to disease of the aorta itself, we will consider after examining our next patient.

Case II.—James B., a negro hotel porter, 35 years old, of temperate habits, has never had syphilis, but has had several attacks of acute rheumatism, the first, seventeen years ago. He has of late years, though still able to do heavy work, had increasing difficulty in accomplishing it, with pain in the chest, palpitations, epistaxis, and hæmoptysis. Latterly he has been compelled to abandon his work. He has been without severe dyspnœa, and rests easily upon his back. Attention is at once attracted to his heart by the very marked throbbing of his arteries and by the forcible abrupt character of his pulse. There is decided prominence of the præcordial region with violent heart action. In the sitting posture his whole body vibrates from the force of his heart-beats. He is before you to be examined, but to recapitulate his symptoms would almost be to repeat those of our first case. There is, however, pulsation in the suprasternal notch and over the carotids to a greater extent, and these vessels can be felt to be greatly distended, while behind the sternal notch the expansile pulse is very forcible and has a pronounced thrill. There is a loud and protracted systolic and diastolic basic murmur. Upon several occasions recently, during a mild attack of rheumatic fever, I have noticed a symptom that I do not remember to have seen mentioned. Over the belly, which otherwise presented no abnormal signs, there was a pulsation not due to the aortic beat, which could be plainly felt in the usual position. It was very perceptible all over the abdomen and *was distinctly later than the beating of the aorta and femoral.* This belly pulsation was not forcible and was not accompanied by a bruit. It was detected everywhere, above, below, in front, and at the flanks. To determine its nature, the patient was carefully studied while talking,

Digitized by Google

when it became evident that it was not voluntary. B. is temporarily better, and of late this pulsation has not been observed, but I attribute it to the continuation of the pulse wave to the smallest arteries of the abdominal cavity and wall, reaching even into the capillaries, and thus giving a pulse that extends to the peripheral vessels an instant later than the wave reaches the femoral in the more direct channel. Another point of interest in our patient is the intense pulsation in the suprasternal fossa and in the carotid arteries. There is no difficulty in determining that this is due to distention and dilatation from the powerful heart contraction, and that it is not due to aneurism, of which all other signs are absent. B. is, like our first patient, absolutely without signs of passive engorgement, a piece of good fortune that he owes to his healthy auriculo-ventricular valves.

It is not difficult to understand why aortic regurgitation is accompanied by this peculiar condition of cardiac hypertrophy and blood pressure; nor is it difficult to comprehend the comparative absence of disabling symptoms in cases where, as at present, the alterations are very far advanced. So long as the mitral valve remains competent, the patient does not suffer passive engorgement in the lungs, the right heart, and the systemic venous system. Dropsy is, therefore, absent. So far as the heart is concerned, the stress falls immediately upon the left ventricle. In order to unload itself, both of the blood received from its auricle and that returned to it through the incompetent aortic valve, muscular hypertrophy and dilatation must occur. A slight degree of aortic regurgitation will be met by the necessary ventricular hypertrophy, and the perfect compensation thus attained will often be maintained for years, the patient perhaps remaining quite unconscious of the defect, provided the alterations at the valvular orifice remain at a standstill. You will, probably, remember an elderly man who was lately in our wards. He was quite unconscious of any cardiac defect, but in the course of his examination a well-marked regurgitant aortic murmur was detected, In him the pulse characters of aortic incompetence were absent, and the cardiac hypertrophy was scarcely noticeable. Perfect compensation being present, the equilibrium was maintained. Another example of aortic regurgitation without pronounced hypertrophy was in a Maltese sailor whom I had before you last winter (see THE MEDICAL NEWS, January 31, 1885). He had the large white kidney and shortly afterwards died from its effects. At the necropsy, his aortic valve was found to be perfectly healthy, and the cause of the regurgitation was a broad plate of atheroma just at and above the sinuses of Valsalva, productive of a purely relative insufficiency.

No such unobtrusive course can be hoped for in the patients before us. Here the heart has had to increase its capacity, both for storage of blood and for overcoming the obstacles that impede its work. As yet dilatation has not outstripped hypertrophy and, handicapped as it is, the heart fairly does its task. In pronounced insufficiency with ventricular hypertrophy, characteristic effects are to be noticed in the vascular system in front. To overcome the effects of the backward flow from the aorta, the heart, with its mighty contraction, sends the increased volume of blood far into the arterial system in a great wave. Normally, the elasticity and muscularity of the vessels squeeze this fluid and force it backward and forward in the directions of least resistance. The backward wave swings together the cusps of the aortic valve. The blood now finding exit by a forward movement, pours along toward the capillaries, filling the vessels as they contract upon it. But if the backward flow continue through an insufficient valve, the contracting arteries empty themselves with a bound, their contents escaping in both directions. To overcome the effects of the regurgitation, the power of the heart is increased by muscular hypertrophy and the blood wave is sent far beyond the limits where the smallest arteries should exert a constant pressure upon a steadily flowing stream, into the capillaries, and sometimes even into the veins. Despite the powerful contraction of the heart and the overfilling of the larger arteries, the reflow into the ventricle is often the cause of a capillary anæmia that may even induce faintness. This anæmia is partially compensated for by increased frequency of the pulse which may always be observed in aortic regurgitation with ventricular hypertrophy, as in our present cases. We explain, then, the hypertrophy, the arterial dilatation, the pulse shock, and sudden collapse in our cases; but we have not accounted for the loud systolic basic murmur in each. It may be due to aortic stenosis, yet a moment's consideration shows that, if this be so, the narrowing is relative, not absolute. In both cases the character of the heartbeat and of the pulse makes it evident that an abnormally large volume of blood passes into the aorta. The orifice is surely not narrower than in health. The murmur may be caused by the stream of blood passing over rigid and roughened structures at the orifice. But there is, in my opinion, a more probable explanation of the murmur, which is that it arises along with the systolic thrill, present in each case, in the dilated aorta; for these signs are known to accompany aortic dilatation, which we know to be present, while besides the bruit there there is no other sign of aortic obstructive disease.

We have seen that aortic regurgitation when not progressive, finds compensation in cardiac hypertrophy and may allow years of useful and comfortable life to its bearer. But no case, however mild, entitles the attendant to give a favorable prognosis. In even slight degrees of aortic regurgitation, dilatation of the left ventricle may suddenly become excessive, and death ensue from heart paralysis. Sudden death is more apt to occur in aortic incompetence than in any other form of valvular disease. Yet each of these men proves to us that a more tolerable degree of comfort is possible in this form of cardiac disorder than when the mitral valve is affected. But it not uncommonly happens that, yielding to the increased strain thrown upon it, and through the widening of the auriculo-ventricular orifice by the dilatation of the ventricle the mitral valve may likewise become incompetent, and vastly augment the patient's suffering. Here is an example of this:

Case III.—H., an Irish laborer about 35 years old, had rheumatism and heart trouble when a youth. His recovery was tedious, but seemed finally perfect and he was able to do ordinary laboring work. About a year ago he began to have dyspnœa, palpitations, chest pains, etc., and three months ago anasarca developed. He was much exposed, got decidedly worse, and was at length admitted to our wards. He complains of dyspnœa, pain in the chest, in the epigastric and hypo-

Digitized by Google

chondriac regions, and of inability to sleep except in the sitting posture. There are general anasarca, lividity of countenance, and great distress. All the symptoms of great cardiac hypertrophy, of aortic regurgitation, and of dilatation of the aorta and great arteries are present and are readily recognized. The regurgitant murmur is quite musical. But a pronounced mitral regurgitant murmur accounts for several important symptoms that our first patients are without. We find here right-sided hydrothorax reaching to the angle of the scapula, and some pulmonary œdema. There is pain in the hepatic region, and there is dulness in the nipple line reaching two finger-breadths below the border of the ribs. The splenic area is also slightly increased. Albuminuria is not a constant symptom, but to-day it is present. Here we have the evils of passive hyperæmia added to those of aortic disease. The left auricle becomes engorged, as do the pulmonary veins and the lungs. This engorgement extends through the pulmonary artery and right heart to the systemic veins and produces passive hyperæmia of the liver, spleen, kidneys, and of the whole venous system with consequent dropsy.

The result of pumping an increased volume of blood with increased force into the aorta tends, as we have seen, to produce dilatation of this vessel and other larger arteries. This may lead to aneurism or its simulation, as in the patient I now show you.

Case IV.—M. is a fresco-painter, twenty-seven years old, and unmarried. Four years ago he was severely injured by a fall from a height, breaking several ribs, etc. Since then he has not been well and has had much pain in the chest. He has been told by eminent authority that he has aortic aneurism. He is a well-built man, but is pallid, and has a distressed expression. He denies syphilis, rheumatism, and alcoholism, but is a victim to the morphia habit, as the scars of countless hypodermatic injections testify. As he sits before you his trunk and head are seen to vibrate with each heart-beat. A heaving motion can be seen over the whole præcordial region. The pulsations of the large arteries of the neck, head, and upper extremities are seen to be violent. A strong pulse is visible in the suprasternal notch. The heart area is increased, and the præcordial region projects. The apex beat is well outside the nipple line in the sixth interspace. There is relative dulness in the upper sternal region, but no increased resistance to the percussing finger. There is no tumor nor circumscribed dulness. Behind the sternal notch one feels an expansile pulse, but the distended vessel is thin walled. The hand placed flat over the first and second interspaces to the right of the sternum perceives a systolic thrill. The heart-beat is heavy and forcible. Upon compressing the thorax in its antero-posterior diameter, there is felt no pulsation separable from the diffused thoracic upheaval. Corrigan's pulse is fairly marked. The radials beat synchronously and in about equal volume. The carotids beat violently and with marked expansion. The femorals pulsate with a violent shock synchronously with the radials.

Over the apex a loud systolic and diastolic murmur is heard. The valve sound cannot be distinguished, and a mitral systolic murmur is clearly present; as the base is approached these bruits become louder, until they are most intense over the first and second interspaces and manubrium. They are heard everywhere over the chest in front, and the tricuspid and pulmonary sounds cannot be separated with satisfaction. There is no simulation of two pulsating centres within the chest so characteristic of aortic aneurism; no shock except that clearly due to the heart's impulse. Both carotids give a pronounced systolic and diastolic murmur. Even in the femorals a systolic bruit can be heard. There is no inequality of the pupils to suggest pressure upon the intrathoracic fibres of the sympathetic going to the iris; the voice is not notably modified. He says he has dysphagia, but those about him assert that he swallows the ordinary solid diet of the hospital without difficulty. He has no cough nor respiratory disorder. The great veins are not compressed. He complains of violent paroxysmal pain in the chest radiating to the shoulder and finger-tips. There is no expectoration; the abdominal organs are not enlarged. There is no albuminuria; anasarca is not present, but he claims to have had it some time since. Our patient is well posted upon the subject of aneurism, and details sensations and signs symptomatic of that disorder. Indeed, he uses his afflictions as his stock-in-trade, and counts upon larger doses of morphia in proportion to the clinical and pathological interest he excites.

Has he aneurism? Let us first consider the negative signs. There is no tumor; no circumscribed thoracic dulness nor pulsation; no simulation of double heart sounds within the thorax; no shock separable from the diffused cardiac upheaval. There is, apparently, no difference in the radial pulses, certainly none in the carotids. The "water-hammer" pulse is maintained; the femoral pulse is very forcible and synchronous with that of the radials; over the carotids a strong double murmur is audible, while a systolic bruit is heard as far as the femorals. There are no signs of pressure except subjectively. On the other hand, there is the expansile pulse in the suprasternal notch, behind which the fingers may feel the distention of the vessel; but the same expansile pulse may be felt over either carotid, and if you compare this man with the first two examined, in whom there is certainly no aneurism, the same pulsations will be perceived. Added to this are the sensations pointing toward aneurism, but we know our patient to be very mendacious. Under observation his sufferings, as described, are not apparent. It is true that had we not characteristic signs of aortic valvular disease, with its consequent cardiac hypertrophy and train of circulatory disorders, a diagnosis of thoracic aneurism might become justifiable; but since we have these, it is maintained that the vascular symptoms are those of dilatation simply, a dilatation that is not unfrequently observed where the cardiac lesions in question are pronounced, and involving not only the aorta, but the innominate, subclavians, carotids as well.

All of these patients present unusually severe grades of cardiac disease. They have reached that point in their lives when their hearts, hypertrophied, as they are, are no longer able to bear efficiently their burden of increased effort. All the energy of their bodies seems to be concentrated upon the task of surmounting the obstacles to the circulation. It is not possible, however, for us to say how long these conditions will continue. While the danger of sudden death is greater in aortic regurgitation from over-distention and paralysis of the

Digitized by Google

left ventricle, we know that the distress and disability are far less than in disorders of the mitral valve when the effects of pulmonary and venous engorgement become developed. Indeed, even now B. is about to seek some light employment. (The sphygmographic tracings shown are the results of complex conditions, and fail to afford features characteriststic of aortic disease simply; their proper study would demand more time than we have at our disposal to-day.)

What can we do for our patients? The damage already done we cannot repair. In two cases rheumatism excited the valvular disease. We are reminded, then, that each renewed attack of rheumatism wil increase the danger of fresh cardiac disorder. The exciting causes of this disease must, therefore, be reduced to a minimum. Proper food, clothing, shelter must be provided. The machinery of life must be protected from the friction that wears it away. All the functions should receive the attention that will encourage their easy performance. Beyond this interference is noxious in very many cases. Those in which valvular defects are met by corresponding hypertrophy find no relief in more active treatment. When the heart appears to become unduly excited, even for its increased responsibility, mild sedatives may be employed, and rest enjoined. Saline cathartics have frequently been beneficial. Cardiac stimulants, real and so-called, usually do harm. They are not called for until the heart becomes enfeebled, until dilatation outstrips hypertrophy, as in advanced cases, or when mitral insufficiency becomes superadded. Digitalis now often produces marvellous results, regulating and strengthening the enfeebled heart, and promoting the secretion of urine. Indications for its use were present in our third case, and we already see marked improvement under the administration of half-ounce doses of the infusion every fourth hour. This improvement will prove, of course, only temporary, but it may endure and make life tolerable for months. Caffein, lily of the valley, and other cardiac stimulants, may be used for the purposes indicated, but will so constantly prove less efficacious than digitalis that we cannot hope that they will supplant it. Arsenic is supposed by some to exert a favorable influence in aortic incompetence (Bramwell). Anodynes, internally and externally administered, will often be necessary to alleviate pain and discomfort.

ORIGINAL ARTICLES.

THE EXTERNAL THERAPEUTICS OF PULMONARY CONSUMPTION; A RETROSPECT OF TWENTY CASES TREATED BY THIS METHOD.

BY THOMAS J. MAYS, M.D.,
OF PHILADELPHIA.

FOURTH PAPER.[1]

IN offering a new method, or rather an old method under a new aspect for the treatment of pulmonary consumption, I do not claim for it infallibility, nor do I propose it to the exclusion of other forms of treatment which are useful; but merely on account of the belief that it is able to show superior practical results to any plan which has been heretofore advocated; therefore, I hope it will not be taken amiss when I undertake to follow in the footsteps of some of my illustrious brethren and take a survey of some of the operations and products of the external method of treatment in this disease.

In my three former communications on this subject I embodied twenty cases in the various stages of pulmonary consumption, with a view to illustrate the practical workings of this method of treatment. In this paper I shall, in the first place, give an analytical table of the whole number of cases—citing the number in the different stages when they came under treatment, together with the result of treatment, whether it ended in recovery, in improvement only, or in death; and then give a condensed résumé of each case as far as necessary to the full elucidation of the object of the paper. The cases are not subdivided into the different varieties of the disease, but are classified under the one broad title of pulmonary consumption, merely because, in a large number of cases, the landmarks which divide one variety from the other are too faint to allow a distinction; nor is it necessary to designate more than the first and third stages in order to grade the severity of the disease, because the second is, at all events, a passing or a transient stage, and is never sharply defined from the first and third:

	Number.	Per cent.
Patients reported	20	
" in first stage	12	60
" in third stage	8	40
" in first stage recovered	12	60
" in first stage recovered, relapsed, but restored again	1	5
" in third stage recovered	5	25
" in third stage died	2	10
" in third stage improved, but will die	1	5
Whole number of patients who recovered, excluding the case which relapsed but which was subsequently restored, as well as the one which improved, but which will die	16	80

CASE I. (*Case I., Series 1*) was in the first stage of pulmonary consumption and came under my care in May, 1879. She then had a cough and profuse expectoration streaked with blood since the previous August. She had hæmoptysis two months before. She had chills and night-sweats, lost in flesh, poor appetite, but bowels and menses were regular. Physical signs were diminished percussion resonance, and crepitation over left apex. She was treated for one month with the external method, when she was restored. She afterwards married, became the mother of a family, and, as far as I know, is well at present.

CASE II. (*Case II., Series 1*) was first seen in March, 1879, in the following condition: loss of sleep, constant cough, profuse expectoration, night-sweats, poor appetite, coated tongue, irregular bowels, and losing flesh rapidly, no hæmoptysis, lost a brother with consumption. *Physical signs:* Dulness, and crepitation in upper two-thirds of left lung. He made a good recovery and is now well and working every day, although a small cavity formed in the middle third of the lung during the treatment.

CASE III. (*Case III., Series 1*) came under treatment in November, 1880. He had a cough, expec-

[1] The first and third papers appeared in THE MEDICAL NEWS for March 8, 1884, and August 22, 1885, and the second appeared in *The Therapeutic Gazette* for June, 1885.

Digitized by Google

toration streaked with blood, stitches in left apex, night-sweats, wasting, and poor appetite. *Physical signs:* Diminished percussion resonance, crepitation and wavy respiration in left apex. He made a good recovery, married afterwards, and became father of a small family. He lost a brother from the same disease.

CASE IV. (*Case IV., Series 1*) became my patient in July, 1883, when she had a cough, chills, lost flesh, poor appetite, no hæmoptysis, weight 100½ pounds. Her father's mother and sister, and her mother's sister died of consumption. She lost a brother at the age of eighteen from some form of lung trouble. *Physical signs:* Dulness over left apex, as well as crepitation. She improved under the treatment, weighed 109 pounds the following 7th of September, and is doing well at present writing

CASE V. (*Case V., Series 1*).—This patient, a boy four and a half years old, was in the third stage when I first saw him in July, 1883. The disease involved nearly the whole of the left lung. There was a cavity in the apex, cavernous râles in the middle, and complete absence of respiration at the base. Weight, 30½ pounds. An uncle of the boy's died of phthisis ten years before. He made a slow recovery, and in the following December weighed 40 pounds. Doing well at present.

CASE VI. (*Case VI., Series 1*) was in the third stage when she came under treatment in August, 1883. She had copious hæmoptysis, lost flesh rapidly, and had a poor appetite, but no hereditary history of the disease. *Physical signs:* Depression and tympanitic sound between clavicle and mammary region on right side, mucous râles at base. Coarse mucous râles also distributed over posterior base and interscapular region of left lung. When the treatment was commenced she weighed 102½ pounds, and in a little more than a month she gained 9½ pounds. She is well now.

CASE VII. (*Case VII., Series 1*).—This is one of the cases which illustrate the value of employing forms of the external treatment which vary in their strength. For it is shown here that when the milder forms of external stimulation, like the flaxseed poultices, have lost their hold on the disease, the more powerful ones, like the steam jacket, will control it again. This patient was ill since June, 1883, but treatment began last of September, 1883, when he had profuse hæmoptysis, poor appetite, was greatly emaciated, and had a family history of the disease. He was in the third stage, and weighed 133 pounds. *Physical signs:* Tympanitic sound over left apex, both anterior and posterior, with slight dulness over third rib. Cavernous and mucous sounds over same region, with a border of crepitation at its lower limit. Prolonged expiration in right apex. He began to improve under the flaxseed poultices, and on October 21st only very few moist râles were audible anywhere in his chest. The cavity became very nearly dry, and his physical condition had improved a good deal; but a few days after this date tubular breathing and moist râles developed in lower half of left lung, over which the poultices had no influence, and he went from bad to worse until November 20th, when his physical condition was as follows: Large cavity in left apex with tubular breathing and mucous râles from lower limit of cavity to base of left lung. Small cavity in right apex, too. I now placed on him the more powerful tin-metal steam-jacket, and by last of following January the moist râles had entirely disappeared from both of his lungs, as well as the tubular breathing, and he had improved again, and at this time he weighed 136½ pounds. In a case where there is such extensive excavation no results of great importance can be expected, when there is no permanent improvement in the appetite. He remained in this state for awhile, but sank and died in the spring of the present year.

CASE VIII. (*Case VII., Series 1*).—This patient came under observation in August 1, 1883, with a great deal of cough, profuse expectoration of dark green color and streaked with blood, no hæmoptysis, night sweats or chills, but hoarseness and a great deal of pain in laryngeal region. He was in the third stage, but had no family history of consumption. Weight 128¾ pounds. *Physical signs:* Left side, tympanitic resonance from apex to nipple, and flatness from here to base. Cavernous sounds from clavicle to nipple, and complete absence of respiration over region of flatness, anteriorly, posteriorly, and laterally. Right lung normal. He steadily improved under the use of the flaxseed poultice, both in symptoms and in physical signs, until August 29th, when he weighed 135½ pounds. The external treatment then lost its influence and he became slightly reduced. The poultice was discontinued on December 9th, and the steam jacket applied. At this time his weight had sunk to 133½ pounds, and his physical condition was about the same as at the time of the last examination, excepting a wavy respiration in upper third of the anterior portion of right lung, as well as broncho-vesicular respiration at base, posteriorly and laterally of same side. After the application of the steam jacket he began to mend. The left lung became permeable, and a few moist and sibilant râles began to manifest themselves in the right base where before was heard broncho-vesicular respiration. All the râles disappeared in the right lung, as well as the wavy respiration, the cavity on the left side became dry, the lower part of same lung resumed its respiratory function in a moderate degree, and the patient, in April, 1884, weighed 137 pounds. He is well at present.

CASE IX. (*Case IX., Series 1*) was first seen in the middle of January, 1884, when he suffered from cough, hæmoptysis, night-sweats, poor appetite and vomiting. *Physical signs:* Impaired percussion resonance and crepitation in right apex. Under the external treatment he began to improve, but he subsequently had a relapse and a cavity formed under the right clavicle. I lost sight of him for nearly a year, but from last accounts he was alive, but not well. He will in all probability die. He was a pauper, and, therefore, very frequently suffered for the necessary supplies of life, and altogether his hygienic as well as other influences offered but little prospect for permanent relief.

CASE X. (*Case I., Series 2*) was in the first stage of the disease with hereditary tendencies when treatment was begun in January, 1884. He had a cough

Digitized by Google

with copious expectoration and hæmoptysis. *Physical signs:* Percussion dulness and crepitation in left apex. Under the external treatment the affection entirely disappeared in less than a month and a half, although he was an old man.

CASE XI. (*Case II., Series 2*).—This patient had a strong hereditary taint and a most unpromising local and general condition when she began the treatment in August, 1884. She had frequent hemorrhages, was very much emaciated (weight 99½ pounds), had a poor appetite, irregular bowels, night-sweats, chills, and fever (temperature 39⅘°), hoarseness, and much pain in the larynx which extended to both ears. *Physical signs:* Barrel-shaped chest, with depression below both clavicles, cavity sounds in left apex, dulness, crepitation and cavernous râles in upper half of left lung. After being treated about three weeks she improved in her symptoms and physical signs. She slept better, coughed and expectorated less, appetite very good, and the evening temperature was but slightly above the normal. At this time there were no moist sounds or crepitation audible in any part of her chest. She remained so until the following December when her throat and chest symptoms became aggravated, and she took a relapse, and died the same month.

CASE XII. (*Case III., Series 2*).—This patient was what may be termed in the second stage when he was placed under treatment, in January, 1885. He coughed, and his expectoration was yellow and blood-streaked, had chills and fever, night-sweats, poor appetite, and irregular bowels. *Physical signs:* Dulness on percussion in right apex, cavernous râles directly beneath right clavicle, and mucous râles from there to third rib anteriorly. Bronchial respiration over posterior aspect of apex extending to spine of scapula. In the course of six weeks' treatment the moist râles had disappeared, a small cavity was present beneath the clavicle, and his appetite was good, and general appearance much improved. When last seen (during present summer), he was doing very well.

CASE XIII. (*Case IV., Series 2*).—This patient came under observation December 5, 1884, and was in the first stage. She had a severe cough, yellow expectoration, hæmoptysis, poor appetite, and night-sweats, and was losing flesh. She was treated with various tonics, among which were the hypophosphites, iron, cod-liver oil, etc., without avail until January 13, 1885, when the flaxseed poultice was applied to her chest. She then showed the following physical signs: Dulness and increased vocal fremitus and resonance over right apex. No crepitation, but bronchial respiration over same region posteriorly and mucous râles anteriorly. March 5th, her chest was free from râles and on April 2d she was able to do her own housework, to which she was not able to attend for six months previously. At present writing she continues well.

CASE XIV. (*Case V., Series 2*).—This patient came under treatment in February, 1885, and was in the first stage. He had a rickety, pigeon-shaped chest, with a deep retraction of the lower end of the sternum. He had a number of copious hemorrhages, was losing flesh rapidly, with dulness and crepitation in right apex, and altogether a most unfavorable outlook. Bleeding ceased, and he began to improve immediately after the application of the poultice. On March 9th crepitation had disappeared, and on April 8th his chest was clear of all abnormal physical signs except a slight diminished resonance and a coarse vesicular sound in right apex, and he went to work at his trade. He continued well until July, when he had a relapse. Hæmoptysis and crepitation reappeared in the same lung, which were checked the second time by the poultice, and at present feels better, but still weak.

CASE XV. (*Case I., Series 3*).—This case was first seen in May, 1885. He was in the first stage of catarrhal basic pneumonia of the left lung, which was characterized by dulness, crepitation, bronchial respiration, and moist râles. Under the rigid application of the poultice for three weeks the râles all disappeared, but some impairment of percussion resonance remained. At present the left lung has a feeble respiration, no râles, and the patient is eating well and gaining in weight.

CASE XVI. (*Case II., Series 3*) was first seen in April, 1885, and was advised various remedies without any benefit. On May 6th the poultice was applied when he presented the following physical signs: Dulness, bronchial respiration, and crepitation over right apex. On June 2d crepitation had entirely disappeared, and bronchial breathing and dulness were much less marked. From last accounts he is doing well, and has gone to work.

CASE XVII. (*Case III., Series 3*).—This patient came under my observation May 18, 1885. She had a cough, yellow expectoration, hæmoptysis, and says that she is the only surviving member of a family of eleven children, all the rest having died of consumption. She had dulness in the left apex extending to second intercostal space in front, and to spine of scapula behind, with marked crepitation in supraclavicular region. She was placed under treatment the same day, and on June 9th crepitation had subsided, and the dulness was less marked. On June 18th hardly a trace of the disease remained, and she continues to feel well up to the present time.

CASE XVIII. (*Case IV., Series 3*) was placed under the external treatment June 2, 1885, when she manifested the following symptoms and physical signs: Constant cough, worst at night, yellow expectoration, night-sweats, chills and fever, losing in flesh, and no appetite. Dulness in left apex, prolonged expiration posteriorly, and wavy respiration anteriorly over same region. On June 16th the dulness had perceptibly diminished, the wavy respiration had disappeared from the front, and in a month more she was well.

CASE XIX. (*Case V., Series 3*) was in the following condition when he was placed under the external treatment on May 6, 1883: Cough, blood-streaked yellow expectoration, losing flesh, chills, and no appetite. Dulness in right apex, and crepitation in supraclavicular region. On June 2d he felt much better, had no more blood-streaked expectoration, and the crepitation was replaced by a prolonged expiration and roughened inspiration. On June 9th very little evidence of any abnormal signs existed. Good recovery.

Digitized by Google

CASE XX. (*Case VI., Series 3*) presented the following conditions on June 18, 1885, when the external treatment was applied: constant cough, dark greenish expectoration, hæmoptysis, dulness and prolonged expiration over right apex. She improved markedly both in symptoms and physical signs, and when last heard from she was doing well.

Estimation of Therapeutic Results.—In forming an opinion of the value of any therapeutic method or agent it is necessary to possess at least an approximate idea of the physical condition of the body before and after treatment is instituted. To obtain accurate data for this purpose is not always an easy task and sometimes impossible. Happily, however, it can be said that this is not generally true of chest diseases. Here we have physical signs which unfailingly characterize and represent the actual conditions in the underlying organs, and by comparing these as they manifest themselves before, during, and after treatment they furnish us an infallible index in regard to the progress or the retrocession of the disease. Moreover, it is not essential to the success of a certain line of treatment that every case under it should have a favorable ultimate termination. If it can only be shown that it has the power to deflect the disease by moderating and improving the physical signs, then we are warranted in believing that it is indicated, and justified in advocating its usefulness.

In estimating the value of the external method of treatment in pulmonary consumption reference will be made here to the analytical table given on a former page. Of the twenty cases reported there was not a single case which did not at some time during treatment manifest some improvement as indicated by a change in the physical signs, and in an amelioration of the symptoms, while five out of the eight cases in the third stage made what is believed to be a good recovery. Two, in this stage, died, and the other one will probably die within the present year. Out of the twelve in the first stage, all but one made a good recovery, and he was at least partly restored by the same method after his relapse (Case XIV.). The length of time which elapsed since the cessation of the treatment of these patients which are restored varies considerably. Of the five patients in the third stage who recovered one is well six years, one two years, one one year, and the rest for periods varying from two to six months since treatment was suspended. One case (XIV.) in the first stage relapsed in five months after he was free from the first attack. He subsequently improved again. Cases VII. and XI. died, and Case IX. will in all probability die. All of these cases were in the third stage.

It may be urged that in many of the cases reported there has not elapsed a sufficient length of time since the treatment ceased to pass judgment on the ultimate prospects of these patients. This is true enough in some instances, and the objection would have some degree of relevancy were the aim here to prove the proposition that once well, always well, but manifestly the principal desire is to obtain a just estimate of the immediate products of the treatment. It must not be forgotten, however, in making up this result, that the time since the recovery of the five cases in the third stage ranges from two to six years, while the time since the restoration of four out of twelve in the first stage varies from one to six years, and since the condition of those cases of more recent duration is just as favorable as, and in some instances more so, than that of the older cases, there is every reason to believe that their outlook is just as good.

Influence of the External Method on Hæmoptysis.—Contrary to the belief that cold is a sovereign remedy as a styptic, the application of heat in the form of hot water has lately attained prominent rank in surgery as a hæmostatic. It will prove itself equally efficient in pulmonary hemorrhage. Case XIV. especially illustrates its efficiency in this respect, This patient had copious bleeding from the lungs, and after other remedies failed to stop it, a hot flaxseed poultice produced immediate beneficial results, and the hemorrhage gradually subsided under its influence. The relapse which he experienced was ushered in by a severe hæmoptysis, and was likewise promptly relieved by a hot poultice. This case is only a type of some others that came under my notice, and I can safely say that in my whole experience with the external application of heat in this disease I never knew it to aggravate the hemorrhagic tendency.

Its Influence on Cough and Expectoration.—It is almost an invariable experience that after the patient has been well poulticed for a few days he "coughs easier and to better effect." The cough which has been tight before becomes more free and the patient coughs up the offending sputum with greater ease. Longer intervals of rest will therefore occur between the coughing spells and the patient obtains relief and economizes his strength from this source alone. The great degree of quietude derived from the poultice is not only of importance during the day, but is doubly so during the night, for it protects the patient from the harassing cough so incidental to this disease during the sleeping portion of the twenty-four hours. Then again the pleuritic stitches which are so common in this disease are often very readily relieved by the local application. After a short course of poulticing they frequently express themselves that they are able to breathe more freely and deeper than before.

Its Influence on the Digestive Organs.—Whatever means or methods are pursued to improve the local condition of the consumptive patient, it must not be forgotten that the ultimate triumph of the treatment depends on the condition of the digestive organs, and on the power of the body to assimilate food. If even the lung difficulty becomes better, there cannot possibly be a constancy in its duration, unless the stomach is able to partake and digest food sufficient to sustain and build up the shattered constitution. Very often the digestive derangement depends in a large measure on the pulmonary disorder, and in such cases it is self-evident that diminution of the latter will be followed by improvement in the former. Therefore it is always a favorable omen if the patient begins to eat more and relishes his food better than he did before treatment. Most of the patients here reported, experienced a favorable change in this direction,—the change was most marked in those in the early stage of the disease.

Influence of Internal Medication.—It may naturally be supposed that the results here recorded are in a great measure due to the influence of cod-liver oil and the hypophosphites, which are generally regarded as having a specific action in this disease. While it is true that in some cases they were administered, and in a general way had a good effect, it is also true that in most of the cases they were discarded, and that in some which terminated favorably the oil positively disagreed. These supposed specifics are admirable in their action, but should never be persevered in when they disagree with the patient, or when they can be supplanted by more efficient agents. Considerable time is often wasted in entertaining wild expectations as to the possibilities of these agents; experience teaches, however, that the physician who administers them with a view of having an action on the local process, other than that which arises from the influence of an improved general condition, will be sorely disappointed.

The Possibilities of External Therapeutics.—The external treatment of pulmonary consumption thus far described assumes importance not only on account of its efficiency, but also on account of the economy which can be practised in regard to the administration of medicinal agents through the stomach. All who have had experience in treating this class of patients will readily admit that the less the digestive organs are used for the purpose of introducing medicines into the system the better for the patient. But the method of applying heat to the chest externally does not by any means exhaust the *armamentarium* of the external treatment in this disease. Other forms of external treatment have been recommended or introduced. Thus Bühl,[1] in speaking of the therapeutics of pulmonary consumption, says (p. 161), "There still remains a wide field for the employment of a rational therapeusis. I would particularly call your attention to the use of external irritation of the skin. This may be by moist or dry friction, and should last a very short time, from half to one minute, or we may employ spirits instead. I would also recommend in some cases the application of a greater amount of heat, as by cloths dipped in oil, or compresses wet in tepid water, and covered with gutta-percha, or the latter substance alone. And, again, Dr. T. Henry Green, in his lectures delivered in the Brompton Hospital for Consumption, in London, says[2] (p. 102), "That in these last named cases (cases where much intra-alveolar matter exists which is capable of removal) attempts to stimulate the circulation in the diseased lungs by cold douches and friction, and other similar means, such as have been recently advocated by Dr. A. von Sokolowski, would appear to me to be more in accordance with the teaching of pathology." The treatment here alluded to is fully detailed by Dr. von Sokolowski in the *Berliner klinische Wochenschrift*, Nos. 39, 40, and 44, for 1876, and consists in rubbing the body, in exercising in fresh air, and in cold douches, either in the form of a spray or of a stream of water. The patient is directed to take a brisk walk, or to have his whole body well rubbed with a coarse, dry towel, in order to excite the cutaneous circulation. Then he is subjected to a cold douche for only four or five seconds at the outset, after which he is hurriedly rubbed dry, dressed, and enjoined to take another active walk in the fresh, open air for at least thirty minutes. If the patient is not able to take the required exercise, he is thoroughly rubbed, and walks as much as he can. In those patients for whom this plan of treatment was suited the most satisfactory results were obtained, and it is certainly well worthy of imitation whenever practicable. It is noteworthy that the friction, the external application of cold, as well as of heat, have all a common therapeutic object in view, viz., that of stimulating or of exciting the affected lung structure and its surroundings, and thereby hasten the process of resolution and resorption of the infiltrated products.

In my first paper on this subject I spoke of *massage* as another useful form of external treatment in pulmonary consumption, and since then I have had further experience with it and find no reason to change my favorable views there expressed. If it is performed properly by a person who has some knowledge of the gross anatomy of the body, its physiological and therapeutic effects become apparent at once. Experiments on the lower animals abundantly prove that massage not only accelerates the motion of the fluids of the body, like the blood and lymph, but that it also serves to stimulate and enhance the function of the nervous system. In this passive manner it invigorates the process of tissue metamorphosis, restores the appetite, and builds up the body. The whole body must be massaged once or twice a day, and no fever or any other condition of the body contraindicates its use throughout the course of the disease. This, then, is another useful adjunct to the external method of treating pulmonary consumption, and should be employed whenever possible.

Prevention of Recurrence.—The greatest *desideratum* in the management of the consumptive class is to make the results of successful treatment permanent and enduring. This, of course, is a question which is beset with many difficulties, and to treat it properly implies a dissertation on the influence of foods, of clothing, of shelter, of exercise, etc.; but one of the chief dangers which confronts people with consumptive tendencies lies in the sudden temperature changes incidental to our northern climate, especially along streams and rivers, where the atmosphere is additionally contaminated by a superabundant humidity. Persons of this class generally have a relaxed capillary circulation of the whole body, and especially of the skin, and are therefore extremely sensitive to the slightest changes in the atmospheric temperature. They perspire readily when it is warm, and are easily chilled when it becomes cool. This liability to sudden oscillations in the capillary circulation of the external and internal coverings of the body constantly exposes them to a liability of inflammatory troubles of the throat and of the respiratory passages, and of course to a recurrence of another attack. Such a body is, therefore, out of harmony

[1] Inflammation of the Lungs, Tuberculosis, and Consumption, by Dr. Ludwig Bühl. G. P. Putnam's Sons, 1874, New York.

[2] Pathology of Pulmonary Consumption, by T. Henry Green. Henry Renshaw, London, 1878.

Digitized by Google

with its environment, and the great object here is to bring it back to its former normal relation. One way to accomplish this, in a measure at least, is to order such people to accustom their bodies, or their extremities only, to cold spongings or baths. They begin the procedure by only bathing the lower extremities for a week or ten days, and then gradually extend to the arms and the body. The parts to be bathed are first briskly rubbed with a dry, coarse towel, then bathed or sponged with cold water; and afterwards rubbed thoroughly again, and then the patient is allowed to take exercise, or to go to bed. This process is repeated morning and evening, or at least once a day, and that in the morning after breakfast. In this manner a natural reaction of the body is brought into play which enables it to resist and throw off the effects of the deleterious temperature changes.

In addition to this the body must be clothed seasonably, and well fed, and the patient be advised to spend as much time as possible in the open air, and thoroughly practise the art of taking deep inspirations with the mouth closed. This can be done very systematically, while he is walking in the open air, by being taught to inspire once for every eight or ten steps, and also expire once for the same number. The swinging of dumb-bells will materially assist in expanding the lungs and chest-walls. In this way the chest or respiratory muscles will be strengthened, the pulmonary circulation increased; and the apices, which are probably in a semi-atelectatic condition, will be more thoroughly inflated, and the tendency to the accumulation of catarrhal products in this portion of the respiratory surface avoided.

Hospital versus Home Treatment.—There can be no doubt that the clinical results which are obtained in hospitals erected and arranged specially for the treatment of pulmonary diseases are superior to those derived from home treatment. This, I am convinced, is true of institutions like those of Gerbersdorf and Falkenstein in Germany, and also of similar ones in England. And why should this not be so? Why should not an institution that is erected in accordance with the most approved ideas of ventilation, of heating, of drainage, and with every other appliance particularly adapted for the treatment of this class of cases give better satisfaction than a building where very few or perhaps none of these requisite conditions exist? The kind and amount of food, as well as of drink, of light, and of exercise, the bathing, the general and special treatment, all require to be carried out methodically, and solely with a view to the greatest possible benefit of the patient, and this can only be done well under the immediate supervision of medical attendants, and in a building constructed for the purpose.

Serious objection is often made against the assemblage of many consumptive patients in one building or locality, inasmuch as it would increase the danger from infection and contagion. There is good ground to believe, however, that the risk from these sources is more imaginary than real. The statistics of the Brompton Hospital for Consumption in London, as collected by Drs. Williams and Humphreys, show that, up to the year 1883, embracing a period of thirty-six years, not a single clearly authenticated case of pulmonary consumption among all the attachés of the hospital during that time emanated from within its walls. During the whole thirty-six years there were twenty-nine physicians and assistant physicians connected with the institution, and among these occurred only a single case of phthisis, and he was tuberculous before he came to the hospital. The rest were all well. Dr. Edwards was resident physician for twenty-six years, yet he showed no sign of the disease. There were employed during the whole period one hundred and fifty clinical assistants. Of these eight died of consumption; but all, except one, were sufferers from the disease before they became connected with it, and in this one case there is doubt as to the origin of the trouble. Among the hundred and one nurses, of which there is a health record, one is suffering from a slow form of the disease, which was possibly contracted while engaged in the hospital, although she is of a tubercular predisposition. She is an old employé, and able to attend to her duties efficiently most of her time. No more positive evidence to show the non-contagiousness of phthisis could be gathered anywhere than is furnished by this large institution. Every one of the individuals associated with this hospital were almost constantly exposed to the virus of the disease, and yet there is only a single case, the source of which could be traced to contagion, and this rests largely on suspicion. Other evidence gathered from other hospitals of the same kind corroborates these statistics. That phthisis is infectious or communicable from man to man, no one, I think, cares to deny; but that it is so contagious that those affected with it require constant isolation, is not warranted by facts, and is too bald an assumption to command serious consideration.

1716 Chestnut Street, Philadelphia.

TWO CASES OF FRACTURE OF THE SPINE; WITH RECOVERY.

By JAMES D. STRAWBRIDGE, M.D.,
of Danville, Pa.

Some weeks since, while attending a patient near Northumberland with Dr. William B. Stoner, my attention was recalled to the following case, of which I had entirely lost sight. At a subsequent visit the patient met me at Dr. Stoner's office, where I had an opportunity to examine and satisfy myself as to the nature of the injury and its result.

Edward B., an able-bodied healthy man of medium size, about 35 years of age, employed at the lumber mills of Frick, Chamberlain & Co., at Northumberland. On May 18, 1882, having done six hours of continuous work, floating logs from the canal, through a narrow channel under the P. & E. railroad, into the sawmill pool, tired and somewhat intoxicated, he sat down to rest on the railway track, and was knocked by a passing locomotive into the pool, from which he was immediately rescued, insensible, apparently with a broken neck, and carried to his home.

A few days later, I was called in consultation by Dr. Stoner and the late Dr. Joseph Priestly, and found

Digitized by Google

the patient on his back in bed, perfectly conscious, suffering but little, without paralysis of body or limbs, his head resting on a pillow, with the face turned strongly to the right, and without power of movement. Having diagnosticated a dislocation of the neck, a decision in favor of immediate reduction necessarily followed. Having placed the patient in a sitting posture Dr. Priestly stood behind him on the bed, and taking the head between his hands lifted steadily until the body was nearly suspended. Dr. Stoner steadied the body, while I manipulated the neck. When considerable extension of the neck had taken place, the face turned to the front and the vertebra glided easily into place, but as soon as extension was relaxed, and the head rested on the vertebra, the neck shortened and the face again turned to the right. Upon lifting the head again slowly, a fracture of the third cervical vertebra, through the bifurcation of the spinous process and through the pedicle on the left side was easily discovered. As soon as the head began to rest on the spine, or the erector muscles to contract, the smaller fragment could be felt pressed outward, while the body and right side retained their position; the axis, directed by the right articular facet, glided backward and to the left, into the vacant space, turning the head around to the right.

Having ascertained the facts, it was decided that as soon as a suitable suspension apparatus could be provided, a plaster splint should be applied to the back and sides of the neck to extend from the shoulders, up under the ears and back of the head. The splint was efficiently applied a day or two later, by Drs. Stoner and Priestly, and worn by the patient four weeks. Becoming impatient of its irksomeness the patient removed it himself, but found he could not yet do without a support for his head and had to have it reapplied. It was worn for three weeks longer and then permanently laid aside. On the 10th of July he returned to his work, and has never since experienced any inconvenience from the injury.

While writing the above, the following case, of which I had no memoranda, seeming worthy of record in this connection, I have obtained the necessary data from the patient himself and the attending physician.

In February, 1867, John M., a robust, healthy man of not over 30 years of age, engaged in mining iron ore, was coming up out of the mine, and seated himself on the front end of an empty car which was being drawn up the slope. The roof of the mine was very low, compelling him to sit bent forward with his head down, but incautiously rising a little, he was caught on the back of his neck and shoulders by one of the roof timbers, which doubled the body on itself, and as the car advanced dropped him backward into it, a crushed and helpless mass. On reaching the surface he was taken out insensible and carried home.

A week after the accident I was called to see him with Dr. B. F. Shultz, of Danville, his attending physician. I found the lower half of the body and extremities paralyzed, the bodies of the seventh, eighth, and ninth dorsal vertebræ were crushed into each other, and sixth and the tenth injured. The heads of the eighth, ninth, and tenth ribs were dislocated on the right side, and the ninth and tenth on the left. The spine from the sixth to the tenth vertebra projected, forming a curve of nearly a semicircle. In this condition he was being moved about in the bed, and raised up when necessary to void his feces, the urine being drawn with a catheter. The attendants were made to understand that he could not be raised up or moved about in bed, and that his only hope for recovery was through maintaining absolute immobility of the spine.

A strong frame was prepared with canvas stretched on it. On this a mattress was fitted with a cavity to receive the curve of the spine; pads were placed on each side so as to keep up a moderate pressure on the necks of the dislocated ribs. A trap was made through the mattress, and canvas for removal of the discharges. On this the patient was kept in a horizontal position for thirteen weeks, without other movement than that of being turned slightly to one or the other side to adjust the pads and to cleanse and protect the skin. By that time paralysis had entirely disappeared, the bladder and bowels had regularly resumed their functions, and the bodies of the injured vertebræ appeared to be solidly united. The patient was then allowed to change his position, and soon after to sit up.

At the end of the fifth month he was out of doors walking about apparently well. He has not since suffered from any spinal trouble, has been, and is now a healthy man. He is somewhat reduced in stature, has a very marked projection of the dorsal spine, and a very stiff back.

MEDICAL PROGRESS.

THE MODIFICATION OF MERCURY COMPOUNDS IN THE ANIMAL ORGANISM.—DR. RICHARD FLEISCHER, in a study of the modification undergone by preparations of mercury in the animal economy, adduces the following facts as the results of his experiments:

1. Calomel, which in pure water is insoluble, in the presence of chloride of sodium is dissolved, and transformed into the bichloride of mercury.

2. The formation of mercuric chloride is favored by a high temperature, *i. e.*, the temperature of the body.

3. The amount of mercuric chloride produced is minute, but plainly recognizable.

4. Dilute hydrochloric acid of a strength of 25 per cent. converts only a minimum portion of calomel into the bichloride. A solution of a strength of 4 per cent. is much more active.

5. By mixture of potassium iodide and calomel, iodide of mercury and potassium and metallic mercury are produced. The double salt produced is soluble in excess of potassium iodide, but separates in pure water, into the insoluble oxide of mercury and into iodide of potassium.

6. The oxide of mercury forms with chloride of sodium, corrosive sublimate and caustic soda.—*Deutsche med. Wochenschrift*, September 3, 1885.

PORRO OPERATIONS.—The fourteenth operation of this nature was performed in the Santa Caterina Maternity of Milan, by Dr. Ettore Truzzi, first assistant of Prof. Porro, on the 4th of August, the woman having a

Digitized by Google

deformed pelvis, the result of malacosteon. On the thirtieth day after the operation the patient was well advanced in convalescence, and the child living and well. In the fourteen operations all of the children were saved. The 1st, 2d, and 9th cases were fatal to the mothers. We have then the very remarkable result of 11 women and 14 children saved under 14 operations by five operators. The last 11 operations were fatal in but one instance, Prof. Porro himself being the operator. The Müller method was performed in case 2, which was one of the fatal ones. The original plan of Prof. Porro has been closely adhered to except in some minor points.

Prof. Breisky, of Prague, performed his sixth operation early in May last, and presented the woman before the Medical Society of that city at its session of June 5th. The patient was 27 years old, a primipara, and affected with deformity of the pelvis, the result of rickets, the contraction affecting all of its diameters, but chiefly to the left side. The child had a large head, which presented at the superior strait. The length of the cicatrix indicated that the operation had been performed according to the modification of Müller.

This is the sixth Porro case of Prof. Briesky, all of which have been operated upon successfully.

Researches upon the Causes of Progressive Locomotor Ataxia.—Dr. Belugou, in a study of the causes of progressive locomotor ataxia, formulates his conclusions as follows:

1. No cause can be cited as exclusively giving rise to locomotor ataxia, or as being a necessary element for its production.

2. The etiological conditions which seem to possess the greatest importance for the genesis of the disease, are syphilis, hereditary nervous disease, rheumatism, and functional abuses.

3. In almost every case, in connection with other etiological conditions, functional excesses and nervous exhaustion play an accessory rôle and contribute, in a degree more or less extended, to the evolution of the disease.

4. The etiology of tabes in the majority of cases may be formulated as follows: In an individual of a highly nervous temperament, hereditary or produced by functional abuse, or as is almost always the case, the first exaggerated by the second, an occasional cause or accident, or chill, or a little less frequently the localization of one of the two diatheses, rheumatic or syphilitic, gives rise to the affection.—*Le Progrès Médical*, September 5, 1885.

Ferrán's Cholera Inoculations.—The following are the conclusions of Prof. Van Ermengen's report to the Belgian Minister of Public Instruction, concerning the cholera vaccinations of Ferrán:

1. Koch's bacillus was present in the stools examined, and the choleraic nature of the disease was certainly established.

2. The vaccine liquids of Dr. Ferrán are produced by cultures of the microbe of cholera.

3. A liquid for second vaccination, on examination, was found to contain the comma-bacillus in a state of pure culture.

The microbes were few and small; their feeble proliferation was due apparently to lack of nutritious matter in the culture material, or to the presence of substances unfavorable to their development.

The vaccine contained none of the varied forms of development described by M. Ferrán.

4. The round corpuscles which M. Ferrán considers *spores* are very probably inorganic matter.

In no case has it been shown that these granulations possess the biological properties hitherto recognized in the resistant germs of bacteria.

5. The mulberry-formed bodies described by M. Ferrán, from which he considers the spores arise, are crystalline masses, as is shown by their solubility in acetic acid, their characteristic form and extraordinary dimensions.

6. The subcutaneous injection of M. Ferrán's vaccine liquid in the quantity of 2 c.c. produces in man phenomena of local irritation and slight febrile reaction, very different from the syndromata of cholera.

They differ also from the symptoms of cholera described by M. Ferrán, in his communication to the Académie des Sciences de Paris (April 15, 1885), which he produced in man by hypodermic injection in smaller quantity, of a virulent culture of the comma-bacillus.

7. In subjects upon whom reinoculation was practised, phenomena of the same nature recurred in the majority of cases, as were exhibited in those inoculated for the first time. It was not proven in those cases in which the phenomena were less pronounced, that the method of inoculation or the composition of the vaccine fluid could not explain the difference in the results.

8. Blood taken from six cases in which inoculation had been practised, from the inflamed tissues and the general circulation, exhibited the characteristics of normal blood, and contained no microörganisms.

9. It remains to be shown that the local inflammation produced by the injection of vaccine is due to a specific action of the microbe upon the tissues, and not to the bile which M. Ferrán adds to his cultures. M. Ferrán did not consent to the performance of control experiments necessary to establish this point.

10. Inoculations in the cases observed have been without deleterious results.

11. It is doubtful whether the vaccine of M. Ferrán is of attenuated cultures. The methods by which they are obtained are unknown to Prof. Van Ermengen, M. Ferrán having refused to reveal them, before he has communicated them to the Académie des Sciences de Paris.

12. Prof. Van Ermengen's experiments show that a noticeable attenuation is spontaneously produced in cultures made *seriatim*, under influences little determined.

13. The statistics collected, hitherto without control, and solely by partisans of the prophylactic system of M. Ferrán, are neither sufficiently complete nor precise to allow any decision whatever to be made as to the efficacy of the inoculations.

14. Experimentation upon animals, the only scientific basis of a prophylactic system, such as M. Ferrán recommends, should seek to establish whether subcutaneous injection confers immunity in diverse ways against the infection.

Such experiments should show whether subcutaneous injection protects, not only from reinoculation by a mortal dose, by the same method, but also against

Digitized by Google

infection by the digestive tract.—*Revue de Thérapeutique*, September 1, 1885.

HYPERTROPHIC RHINITIS. — DR. FONTANILLES (Thèse de Bordeaux, 1885) describes this affection as a generalized or circumscribed swelling of the mucous membrane. The causes of the disease are general or local. Under the first may be placed scrofula, syphilis, herpetism, chronic and acute coryza. Local causes are most important in the production of the disease. Unusual size of nostrils, the air entering largely by this path, is a chief source of irritation. Further, the foreign matters thus introduced are larger and more numerous according as the current of air is more powerful. Absence of hairs at the orifice of the nostrils and snuffing, according to Beverley Robinson, are frequent causes of the disease, as are also cold nasal injections.

The functional symptoms are those of nasal stenosis. Objective symptoms are furnished by the appearance of the mucous membrane, the seat of swelling, its form and consistence.

The progress of the disease is mild and continual; its duration prolonged. It may be complicated with loss of smell, difficulty of respiration, and difficulty of hearing, and vision may be affected by obstruction of the nasal canal.

Concerning the nature and treatment of the affection, Dr. Fontanilles reaches the following conclusions:

1. That the affection is not only a symptom, but a morbid entity, whose existence is perfectly determined.

2. It should not be confounded with chronic coryza, naso-pharyngeal polypi, or adenoid vegetations.

3. Its complications, serious at times, are of such a nature that they deserve peculiar attention.

4. Its treatment, always followed by success, is cauterization by the galvano-cautery, or crystallized chromic acid.—*Revue Mensuelle de Laryngologie, d'Otologie, et de Rhinologie*, September, 1885.

SANITARY MEASURES AGAINST CHOLERA.—The Section of Medicine in the Congress of the French Association for the Advancement of Science, held August 12, 1885, unanimously declared that land quarantine, sanitary cordons, and fumigations are useless and dangerous measures against the disease.

The cholera should be arrested at its entrance at the Red Sea.

The only precautions upon the frontiers should be:

Medical inspection of travellers, together with inspection of wagons, and the disinfection of bedding, garments, and miscellaneous objects by moist heat.

Maritime quarantine should be imposed according to the degree and form agreed upon by the International Conference at Rome.

The Congress further declared that the sanitation of cities by cleanliness, is the only efficacious means of staying the progress of the epidemic.—*Le Progrès Médical*, August 22, 1885.

THE TREATMENT OF PULMONARY TUBERCULOSIS.—PROF. DE RENZI, in thirty-one cases of pulmonary tuberculosis, of which seventeen were men and fourteen women, instituted the following treatment:

1. Internally, tonics and antiseptics were administered. Among the first were quinine, phosphate of lime, etc.; and among the second, creasote, the alkaline carbonates, and iodoform.

2. Local treatment by inhalations of ozone, nitrous vapors, iodoform, and turpentine, with expirations into rarefied air, followed by inspiration of compressed iodized air.

The results recorded are:

One patient cured; two months after his departure from the hospital, auscultation revealed no abnormal thoracic symptoms.

Of the remaining cases five were benefited, while twelve experienced no change whatever, and three died.

Prof. de Renzi particularly recommends inhalations, with the exception of those of alkaline reaction. Alkalies, however, taken internally, have increased the weight and improved the general condition of two-thirds of the cases.—*L'Union Médicale*, September 5, 1885.

HYPNOTISM AS A METHOD OF TREATMENT OF INSANITY, AND THE APPLICATION OF SUGGESTION WITH THE INSANE AND NERVOUS.—At the recent meeting of the Society for the Advancement of Science M. VOISIN reported the following conclusions relative to the treatment of insane and nervous patients, affected with partial delirium or maniacal excitement, by hypnotism:

1. Hypnotism produces an immediate and striking effect. The slumber and calm thereby produced could be caused by no drug, to such an extent, without danger.

2. There results therefrom a series of consecutive phenomena, under the head of which it is necessary to place diminution and suppression of the morbid habit.

3. Hypnotism permits the employment of suggestion and the production by its means of modification of ideas, character, and instincts; the return to labor, manual and intellectual; the cessation of hallucinations and of delirious conceptions; the reëstablishment of the organic functions; the suppression of gastralgias and enteralgias; and the possibility, consequently, of regular alimentation of the insane and nervous, who refuse to eat and are deprived of good hygiene and its favorable consequences.

4. Hypnotism still further permits the obtaining of information from those patients who refuse to say anything which will enlighten the physician as to the pathology and causes of their nervo-mental condition, and of giving physical and moral attention appropriate to their disease.—*L'Abeille Médicale*, August 31, 1885.

CALCULUS OF THE TONSIL.—Cases of calculus of the tonsil have been reported by Louis, Monro, Passaguay, and others, but they are not of frequent occurrence. M. TERRILLON exhibited one of the size of a nut at the French Association for the Advancement of Science. It was taken from a man, aged fifty years, who had been subject to attacks of acute and subacute inflammation of the tonsils. As the tonsil was swollen, lobulated, very hard and painful, a diagnosis of cancer was considered to be not improbable. Exploration with the finger and a probe, however, detected the calculous body, which was easily removed. The symptoms passed away under the employment of emollient and astringent gargles.—*The Lancet*, Sept. 19, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, OCTOBER 10, 1885.

THE CHOICE OF METHODS IN ABDOMINAL DELIVERY.

THE announcement that the fourteenth Porro-Cæsarean operation at the Santa Caterina Hospital, in Milan, and the sixth of Prof. Breisky, of Prague, have ended with success to mother and child, brings to mind the question as to the proper form of abdominal delivery to be selected in cases in which the fœtus cannot be extracted through the natural passages without very serious risk to the mother.

During the period when Prof. Chiara, now of Florence, was Chief of the Santa Caterina Maternity, the Porro method of delivery by laparotomy and amputation of the uterus through the cervix was introduced to the exclusion of the old Cæsarean operation, which had been marked by a high rate of fatality. The first and second operations, the latter by the Müller modification, were fatal to the women, but the succeeding ones by him, his two assistants, his successor, Prof. Porro, and his first assistant, have saved all of the women but the ninth, and all of the children. Photographs of the third, fourth, fifth, sixth, seventh, and eighth cases, taken after recovery, and now in this city, bear evidences of good health in their appearance. The ninth case was the first operated upon by Porro, and proved fatal from a rare sequel of the procedure, namely, the strangulation of a knuckle of intestine from an adhesion to the abdominal wound. The tenth, eleventh, twelfth, thirteenth, and fourteenth operations have saved the mothers and children. Thus, twelve successive operations since the first two fatal experiences, have, under the strictly Porro method, saved eleven women and twelve children, in the hands of five different operators in the same hospital.

Prof. Breisky, from the first, adopted the long incision of Müller, and has had uniform success with his six cases, saving both the women and the children. There may be some difference of opinion as to which operation gives the better promise of success, but in the comparison, from this point of view, there can be no question, as the results, thus far, have been similar. The special advantages of the Müller modification are shown in cases in which the placenta is located in the line of incision, or in which the uterus has contained a putrid fœtus, with putrescent fluid and gas, which threaten septic poisoning, either directly or by escape of the fluid into the abdominal cavity upon the opening of the uterus *in situ*. It must be remembered that operators have failed in several cases in the attempt to turn out the unopened uterus after making the long incision, and that its evacuation within the abdomen saved a majority of them.

In cases in which the obstruction to delivery is caused by a fibroid tumor of the cervix, or of the lower segment of the uterus, which cannot be pushed up out of the way, or enucleated, the proper operation is the old Cæsarean, as the lesion of the uterine tissues renders amputation and constriction of the cervix unadvisable. Cases of fibroid tumor are very apt to be fatal, nine having died out of thirteen in the United States after gastro-hysterotomy, not so much because of the uterine disease, as because of the delay in operating, and the persevering attempts to deliver by the forceps, or by craniotomy. Such subjects generally die of shock or septicæmia in a short time.

In hospital practice, the Porro operation has been far less fatal than gastro-hysterotomy. In this country, the latter operation has been tried eight times in hospitals, and always with a fatal result to the mother.

In country practice in the United States, we would recommend the old operation, and for the following reasons: 1. It requires less assistance than any of the new methods, and has been performed often with but one medical assistant, and several times without even this. 2. Country women are much more likely to recover than the poor of cities, and an early use of the knife will save seventy to seventy-five per cent. of them.

In impacted transverse positions of the fœtus, in which an arm generally protrudes, the old operation is to be preferred, as the removal of the uterus is not justifiable where the pelvis is normal. Amputation of the neck of the fœtus, or evisceration may prove more serious than the Cæsarean operation, and in this country we are encouraged to prefer the latter, because of the fact that eight out of eleven women have been saved. As the subjects of this form of dystocia are usually in full health, and possess great physical advantages over those deformed and dwarfed

Digitized by Google

by rickets, the prognosis in their cases is much more favorable, even after considerable delay before resorting to the knife.

The Sänger method of closing the uterine wound in concluding the old operation, is to be preferred, as it secures the abdomen against uterine leakage and its consequent risks. The resection of the muscular coat is not a requisite of success, and the dissecting loose of the peritoneum has been shown to be useless, as the welting of it into the uterine wound may be effected by sliding over the edge of the muscular coat its loose serous envelope, and bringing the two outer surfaces in contact. Six women out of twelve have been saved by this method; one operator, Dr. Leopold, of Dresden, having rescued four women and five children by five operations, as shown in a recent article, by Dr. Harris, in the *American Journal of the Medical Sciences* for October, 1885.

Laparo-elytrotomy has also saved six women out of twelve, and has been particularly successful in New York and Brooklyn, where six out of nine women have recovered. This operation promises better after delay than any other, as it avoids an element of danger in the non-incision of the uterus. Like all the other forms of abdominal delivery, the prognosis will be more favorable in cases where there has been the least delay, although women have recovered after labors of four days, and a week. In many forms of dystocia, this variety of operation will be found impracticable. This is the case in occlusions of the os uteri by tumors of the cervix, cancer, and obliteration due to diffuse cervicitis and infiltration. As the gaping of the lips of the incision of the uterus and the escape of fluid into the abdominal cavity are the chief elements of danger in gastro-hysterotomy, laparo-elytrotomy, which avoids both, ought theoretically to be less dangerous, and should be more successful, especially in Great Britain, where even early performed gastro-hysterotomy loses 75 per cent. of the women.

TUBERCLE BACILLI AND GIANT CELLS.

THE beautiful researches of BAUMGARTEN, of Königsberg (*Zeitschrift für Klin. Med.*, Bd. ix.), who discovered the tubercle bacillus independently of Koch, bring us a step nearer the solution of the question of the relation of the bacilli to the early tissue-changes in tuberculosis.

Briefly stated, the results which he has obtained by the study of artificially produced tubercle of the cornea and iris, are as follows: The first effect of the penetration of the bacilli into the tissues is seen in the fixed cells, which under the stimulus proliferate, showing the characteristic nuclear changes, with the production of large epithelioid and giant cells. A migration of leucocytes from the vessels in the affected region then takes place, and by a concentration of these about the foci of tissue proliferation, the well-known miliary tubercles, consisting of lymphoid and epithelioid elements, are produced. No further progressive changes can occur, and by a gradual process of caseation the final stage is reached.

Two points seem very clearly demonstrated by these investigations; first, the primary proliferation of the fixed elements before any trace of the presence of leucocytes or lymphoid cells; and, second, the development of the giant cells out of the epithelioid elements by a process of nuclear multiplication in which the cell body does not participate.

WEIGERT has sought to trace the relation of the bacilli to the giant cells, and his investigations (*Deutsche med. Wochenschrift*, No. 35) supplement those of Baumgarten in an interesting manner. These structures, as is well known, are peculiar in the arrangement of the nuclei at the periphery, either as a continuous mantle, as a crown, or as a girdle, while the larger part of the cell body is free. With Arnold and Baumgarten, Weigert believes that they take their origin from fixed tissue elements, and do not arise by any such process as a confluence of cells. That the nuclei alone divide, and not the entire cell with the formation of similar ones, must be regarded as an indication of defective cell energy, and not an excess, as usually supposed; and Weigert seeks to associate this defect with the presence of the bacilli.

The frequency of the occurrence of bacilli in the giant cells has been noted by all observers, and they occupy by preference that portion of the cell, just within the nuclei, at the margin of the homogeneous central substance. They are rarely found in this part; in one hundred cells, only eleven bacilli were in the granular non-nucleated portions. The distribution in the cells is quite analogous to the peripheral position which they occupy in older tubercles which have caseated. It is suggested that the bacilli in the giant cells induce a partial necrosis of the protoplasm, and hence the inability of the cell to undergo division and the peculiar grouping of the nuclei and microbes at the peripheral portion. Death of only a part of a cell is not unknown in normal and pathological processes, and Weigert refers to the goblet cells of the intestine, to the epithelium of the kidney, in which he has shown a partial necrosis can occur; and to the hyaline degeneration of muscle, as somewhat similar processes. The central non-nucleated part of a giant cell, on this view, may be regarded as a focus of caseation induced by the destructive, necrotic influence of the tubercle bacilli.

PUERPERAL APHASIA.

THE term puerperal is frequently used without that limitation which its etymology indicates. While this word essentially relates to the condition of a wo-

Digitized by Google

man who has recently given birth to a child, some have also applied it to that of pregnancy, and hence for them the puerperal is not only the recently delivered, but also the pregnant woman.

There is another respect in which the limitation of the term has been transgressed. It has been applied to pathological states that may occur in pregnancy, in labor, or in childbed, the former being dependent on the latter; thus we have puerperal convulsions, though, strictly speaking, eclampsia ought to be distinguished as that of pregnancy, of labor, or of childbed, only the latter being puerperal. Nevertheless, this extension of the term is convenient, and is not likely to lead to error.

In addition to these liberal uses of the word, it has also been applied to affections that are merely accidental in the puerperal woman; they may modify that state, or be modified by it, but they may occur quite independently of such condition, and do thus occur most frequently. Should this disposition to label with the word puerperal all diseases and accidents of childbed continue, we may yet have in textbooks a chapter upon puerperal toothache, puerperal fracture, puerperal coryza, etc.

These reflections have been suggested by an interesting paper found in a recent number of *L'Encéphale*, entitled "Des Aphasies Puerpérales," by Poupon. The author comprehends under this term the different varieties of aphasia occurring during pregnancy or in childbed. The affection is a rare one, he having been able to collect but twelve cases.

In regard to its etiology, in three instances it seemed to be consequent upon albuminuria, and in one upon septicæmia. Independent of these cases, Poupon regards puerperal aphasia as due either to vascular or to nervous disorders. The vascular disorders may be divided into two classes. The first includes congestion, and anæmia, and the second either hemorrhage, or thromboses, or emboli. He states that the only one of these which has been demonstrated is embolism, although, certainly, congestion was the cause in some of the cases.

In regard to aphasia of nervous origin, this may occur in the hysterical, or it may result from a profound mental disturbance independently of any tendency to hysteria. The aphasia may last only twenty minutes, or half an hour, or for several days.

In the aphasia consequent upon embolism, there is usually right hemiplegia with predominant paralysis of the arm.

The prognosis of puerperal aphasia is generally favorable. In almost all cases in which the disease is of nervous origin, recovery takes place. The other forms of the disease are so remarkably mitigated that one may regard them as almost cured. It is probable that in these cases the collateral circulation is reëstablished sufficiently for the brain to regain its functions. Such reëstablishment is more likely to occur because the subjects are young, and the arterial system in good condition.

Women who have suffered with puerperal aphasia ought to avoid pregnancy, since the disease may return.

The treatment will differ according to the cause of the aphasia, but in this, as in other forms of the disease, an effort should be made to exercise the faculties of the patient, and, as it were, to reëducate her, avoiding too long or too frequent *séances*.

We think the majority of our readers will doubt the propriety of making a special variety of aphasia, that which may occur in a pregnant or in a puerperal woman, since it is exceedingly rare, and since its necessary connection with the woman's state is not in all, or even in the majority of, cases conclusively shown.

SMALLPOX IN MONTREAL.

The city of Montreal is now paying the penalty of neglect of one of the most certain means of preventing disease that modern investigation has ever disclosed. If there be a malady whose spread is subservient to human control, that malady is smallpox. If the world could be convinced of this fact and could be made to adopt the practice of vaccination, this most loathsome of diseases would cease to exist in epidemic form. But at present no such hope need be entertained; the most that can be expected is the restriction of the scourge to moderate outbreaks.

What is now occurring in Montreal is but the repetition of the experience of other cities that have been careless about the administration of sanitary government. When the infection of smallpox was first carried into Montreal, the conditions were most favorable for the spread of the disease. A large proportion of the community was unprotected by vaccination, and indifferent or opposed to the employment of this means of security. The sanitary service was totally inefficient, and, in consequence, no adequate preventive measures were employed to limit the infection to its starting-point. Little or nothing was done to restrict the disease until it assumed the proportion of an epidemic, and secrecy was no longer possible. Not until valuable time had been lost was an attempt made to reorganize the sanitary government and employ radical measures against the further spread of the scourge. These measures have met with resistance. The inflamed condition of the public mind has afforded an opportunity, of which advantage has been taken by the malcontents which infest all cities, to mislead the ignorant classes, stir up their prejudices, and incite them to deeds of violence. Riot and bloodshed have been the consequences. Such, within a few short weeks, has been the experience of the city of Montreal, growing out

Digitized by Google

of a state of unpreparedness to meet and cope with a disease which is absolutely preventable, and which, notwithstanding this fact, is continually slaying its victims by thousands.

This experience should serve as a warning to other places to at once make sure their defences against the inroads of this disease. It has been some time since smallpox has been prevalent in this country, and in its absence the people are apt to relax their vigilance. Let vaccination be generally practised, and preparation be made to treat promptly and with adequate measures the first and every case that makes its appearance in any community. If this be done, there will be no danger of the spread of smallpox from the infected centre of Montreal.

The Journal of the American Medical Association announces that the first meeting of "The Executive Committee of the Ninth International Medical Congress" was held in New York, on September 24th. Drs. Flint, E. S. F. Arnold, Dennis, A. B. Arnold, Briggs, H. H. Smith, J. Lewis Smith, Pancoast, Marcy, and Robinson being present. The Committee organized by the election of Dr. H. H. Smith as Chairman. A new office, that of Associate Secretary-General, was created, and Dr. Dennis was elected to fill it, and "another," whose name, evidently for prudential reasons, is withheld, was appointed to the Chairmanship of the Finance Committee.

"To prevent," says the *Journal of the Association*, "all further misunderstanding, both at home and abroad, the Committee unanimously adopted the following resolution:

Resolved, That this Executive Committee enters upon the management of the affairs of the Ninth International Medical Congress, with the understanding that, in accordance with Rule No. 10, its powers are not restricted except by the rules and regulations adopted Sept. 3, 1885, by the Committee of Arrangements appointed by the American Medical Association in April, 1885; and that the actions of this Executive Committee are final, not being subject to revision, amendment, or alteration by either the Committee of Arrangements or the American Medical Association."

The *Journal* adds that "the proceedings of the Committee were characterized by entire harmony and a commendable zeal in pushing forward the proper preparations for the Congress," but makes no comments on the remarkable resolution which was adopted, probably because they are superfluous, since it has uniformly declared that "the Association in conferring these powers and duties upon its Committee, by no means abrogated its own authority in the premises." Moreover, the organ of the Association warmly endorsed the opinion of Ex-Speaker Randall, which it published last July, in reference to this controversy, that the "theory that a select committee created by a body with certain defined powers and duties gives any *vested rights*—so to speak—which place it above or beyond the power of the creating body to review or regulate, is one not only without precedent in parliamentary law, practice, or history, but is untenable on any ground of parliamentary principle. A legislative or other body may, if it sees proper, temporarily delegate as a matter of convenience, certain of its powers and functions to a select or standing committee, but it does not thereby part with its inherent right to resume that power whenever it chooses, and that right is one which the committee cannot question."

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 1, 1885.

THE PRESIDENT, ABRAHAM JACOBI, M.D., IN THE CHAIR.

THE PRESIDENT, in opening the first meeting of the Academy after the summer recess, made the following address:

FELLOWS OF THE NEW YORK ACADEMY OF MEDICINE: It is a source of intense gratification to me to greet you this evening in the beginning of a new season of coöperative work, after a long vacation. May the labors of the coming months be successful both for ourselves and for the medical world, *Ars longa, vita brevis*. Art is so extensive, indeed, and life so short, that we have to concentrate all our efforts to accomplish a certain amount of result.

In behalf of our common interests I crave your attention first for a few facts which I consider of great importance in regard to medical progress. They are connected with the session of the International Congress held in Copenhagen from the tenth to the sixteenth of August, 1884. In a general meeting, held on August 14th, upon propositions made by Sir James Paget, of London; Prof. Ewald, of Berlin; Prof. Bouchard, of Paris; and Dr. Billings, of Washington, the following resolution was passed: That an International Committee be formed for the Collective Investigation of Disease, in connection with the work of the International Congress, and that a certain number of gentlemen do represent their respective countries thereon. The gentlemen designated for that purpose were Trier and C. Lange, of Copenhagen; E. Bull, of Christiania; Rauchfuss, of St. Petersburg; Ewald and Bernhardt, of Berlin; Schnitzler, of Vienna; Pribram, of Prague; Korányi, of Buda-Pesth; D'Espine, of Geneva; Bouchard, of Paris; Lépine, of Lyon; Sir Wm. Gull and Mahomed, of London; Humphry, of Cambridge; Sir Joseph Fayrer, for British India; Gutierrez-Ponz, for South America; N. S. Davis, of Chicago; A. Jacobi, of New York; and Isambard Owen, Secretary-General, of London. The only changes which have since taken place in the list

Digitized by Google

of membership have been brought about by the untimely death of Dr. Mahomed, and the addition of Axel Key, of Stockholm, and Runeberg, of Dorpat.

According to a circular distributed by the Secretary-General some time ago, "the main objects which the Committee seeks to attain through the collective investigation of disease are to widen the basis of medical science; to gather and store the mass of information that at present goes to waste; to verify and correct existing opinions; to discover laws where now only irregularity is perceived; to amplify our knowledge of rare affections; and to ascertain such points as the geographical distribution of diseases and their modifications in different districts. It will be its endeavor to place clearly before the whole profession the limits and defects of existing knowledge, as well as to stimulate observation, and to give it a definite direction."

These are both the motives and the propositions of the Committee appointed at Copenhagen. In regard to them, and collective investigation in general, the favorable opinion of the profession has been expressed frequently. But now and then a voice is still heard disparaging its utility, and discouraging the collection of facts on a large scale for the reason that the procedure has not yet been demonstrated to be useful. Indeed, it has not, for it has never been tried to a large extent. We shall hardly insist, however, that the ground-stone must not be laid because the tower is not yet on the edifice; that the seed must not be sown because the fruit cannot be harvested to-day or was not gathered yesterday.

As to the usefulness of collective investigation, the opinions will become all but unanimous. The efforts of the British Medical Association and the Medical Society of Berlin, and the fair success of an attempt at solving a problem connected with the etiology of croupous pneumonia, made in the Medical Society of the County of New York, during the last year, are sufficiently promising for the collective investigations of the future. In their interest it is that I propose to make a further communication, and request your coöperation.

The Central Committee on Collective Investigation of the International Congress has selected the following subjects, viz.: Rickets, chorea, acute rheumatism, and cancer, planned a number of simple questions in regard to them, mainly to their etiology, and expects as simple answers. Being the secretary of the American subcommittee, I have gathered all of them in pamphlet form, added a few introductory general remarks supplied by the Central Committee, and present herewith a specimen for your inspection. Those of you—I hope all of you—and those of the profession at large who will learn of this request, are respectfully asked to interest themselves and their friends in behalf of the undertaking, notify me of their desire to be furnished with a copy, and comply with the suggestions of the committee contained therein. We do not look for immediate achievements. For the complex of sciences and arts called medicine, has required thousands of years to arrive at its present condition; the aggregation of many wills and forces has resulted in a slow evolution only. No single discovery, even, nor the first attempts at collective investigation, will effect a revolution in medicine. But what we do hope to accomplish, is the gathering of facts on the strength of an improved method, the confirmation of old and the acquisition of new knowledge, and thus to contribute to the success of at least this one committee. It need not matter how much may have, nay, has, been done, to mar the success of the next International Assembly, and to deprive us of the opportunity long looked forward to, of greeting the giants of science, the celebrated teachers, the ingenious experimenters, and our literary or personal friends of Europe, on our own soil. For an International Congress will never convene under the roof of a house divided in itself, though the division may be the work of a few sacrilegious hands only.

But this is a sad theme, known to everybody here, deplored by everybody who feels as both a personal grief and a public calamity the humiliation which is involved in the hesitation on the part of the Congress to assemble in our country.

It is in profound sorrow that I pass by the subject; I prefer to speak of another topic, which, while it is not directly connected with any of the aims and immediate purposes of this Academy, concerns us as professional men of the State of New York and the Union. I allude to the almost unexpected success on the part of the profession of the State of New York in harmonizing a large majority of the medical men of the United States.

Let me explain. Chapter II. Art. IV. Sec. I. of the Code of Ethics of the American Medical Association reads as follows: "A regular medical education furnishes the only presumptive evidence of professional abilities and acquirements, and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless, as in consultations the good of the patient is the sole object in view, and this is often dependent on personal confidence, no intelligent regular practitioner, who has a license to practise from some medical board of known and acknowledged responsibility recognized by their association, and who is in good moral and professional standing in the place in which he resides, should be fastidiously excluded from fellowship, or his aid refused in consultations when it is requested by the patient. But no one can be considered as a regular practitioner, or a fit associate in consultation, whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry."

This paragraph has so often been criticised by both friends and adversaries, that it is unnecessary to refer again to its contradictions, its "nevertheless" and "but," and to its implied acknowledgment of modern "homœopathy." For let us not forget that the Code of Ethics of the American Medical Association saw the light forty years ago, and that what they call "homœopathy" now-a-days, differs from Hahnemannism of those times in every thing but the name. They now claim that their practice is not based on an exclusive dogma, they claim to teach in their schools, and do teach, anatomy, physiology, pathology, and organic chemistry, and thus come up to the requirements of the above article of the Code of Ethics of the American Medical Association. *Indeed, if there were no better grounds for their rejection, they would to-day be entitled to membership in the Association.*

What the Medical Society of the State of New York,

Digitized by Google

in its sessions of 1882 and 1883 adopted in its stead (*Trans. of the Med. Soc. of the State of New York* 1882, p. 75), in a code of medical ethics which covers two pages instead of the eighteen pages of the Code of Medical Ethics of the American Medical Association (*Proceedings of the National Medical Conventions, held in New York*, May 1846, *and in Philadelphia*, May 1847, p. 91–106) reads as follows:

"Members of the Medical Society of the State of New York, and of the Medical Societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine. Emergencies may occur in which all restrictions should, in the judgment of the practitioner, yield to the demands of humanity."

Compare with these brief sentences the explanatory declaration of the American Medical Association passed unanimously in its session at New Orleans of April 30, 1885. There and then it was

1. "*Resolved*, That clause first of Art. IV., in the National Code of Medical Ethics, is not to be interpreted as excluding from professional fellowship, on the ground of differences in doctrine or belief, those who in other respects are entitled to be members of the regular medical profession. Neither is there any other article or clause of the said Code of Ethics that interferes with the exercise of the most perfect liberty of individual opinion and practice.

2. "*Resolved*, That it constitutes a voluntary disconnection or withdrawal from the medical profession proper, to assume a name indicating to the public a sectarian or exclusive system of practice, or to belong to an association or party antagonistic to the general medical profession.

3. "*Resolved*, That there is no provision in the National Code of Medical Ethics, in any wise inconsistent with the broadest dictates of humanity, and that the article of the code which relates to consultations cannot be correctly interpreted as interdicting, under any circumstance, the rendering of professional services whenever there is pressing or immediate need of them. On the contrary, to meet the emergencies caused by disease or accident, and to give a helping hand to the distressed without unnecessary delay, is a duty fully enjoined on every member of the profession, both by the letter and the spirit of the entire code.

"But no such emergencies or circumstances can make it necessary or proper to enter into formal professional consultations with those who have voluntarily disconnected themselves from the regular medical profession in the manner indicated by the preceding resolution."

After these resolutions had been passed in New Orleans, many of the professional men who always persisted in adhering to the code of the American Medical Association were of the honest opinion that they had, by accepting them, removed every discrepancy of opinion or difference of action on the part of those adhering to either the old or new Code; for it is true that the explanatory declaration of Chapter 2, Article IV., Section 1, exhibits a great resemblance to the New York Code of 1882. For the Medical Society of the State of New York, it must be a source of intense gratification to be convinced by the passing of that declaration that a few years have sufficed so to change public opinion as to oblige even the American Medical Association to recognize the justness of most of the New York proceedings. Upon this result the New York State Society can but be sincerely congratulated, and the spirit of equity and justice as displayed by the Committee drafting the explanatory declaration must be commended.

The expressions of opinion in regard to the wholesome effect of the New Orleans declarations have been very numerous. I am in possession of several letters containing remarks full of satisfaction and hope. A gentleman well and deservedly known in the professions of both hemispheres, and markedly so with us for his allegiance to the Code of Ethics of the American Medical Association, gave enthusiastic expression to his delight over the satisfaction that declaration must give, and to the hope that the New York Academy of Medicine would give a public utterance in that direction. That would immediately settle all difficulty about the Code, and at once restore peace and harmony in the profession. I had to tell him that the Academy excluded all politics, ethical or otherwise, from its discussions, and that the only societies which could act in the matter were the medical societies of the county and of the State of New York. There the matter then rested, for I believe I was right in excluding it from any consideration in our midst.

Still, while this Academy is no political body, old and new codes, as far as I know, being equally represented with us, we are an integral part of the body medical, and the events in the professional world affect our interests and sympathies intensely. Thus we have to regret that the wording of the resolutions of New Orleans is very apt to obscure their meaning. Emergencies are acknowledged to be binding; but, while the New York Code admits that a physician may (not shall, or must) consult with a legal practitioner in a case of emergency, the explanatory declaration of the Association insists that such a meeting is not a meeting in the usual meaning of the term, and such a consultation "no formal professional consultation."

The differences are rather slight, it is true. If, in spite of that, the Code question is still made a war cry by some, that fact reminds us of the bloody wars, and persecutions directed against former friends because of nominal differences of ecclesiastical opinions, in the history of the church. It is also explained by the intense enmity exhibited under all circumstances by those who have been convinced against their will. In a few instances we have to deal with the zeal displayed by converts who, after they had greeted the birth of the new Code with congratulations were induced by certain external circumstances to change what they call their minds within the period elapsing between the appearance of two monthly numbers. Or, what is still more, shall I say surprising? shall I say sad? there are those who fought the new Code because they longed for a fight, without caring on what account. A gentleman who edited a sprightly and rattling journal at that memorable time, and voted the "regular ticket," and was by no means gentle towards the new Code men and principles, has convinced and assured me he never read the new Code. I believe him. There are others again—their number has been large at all times—whose souls and sensibilities are moved by shibboleths, by single words, provided these words are skilfully handled by shrewd calculation.

Digitized by Google

"Just where fails the comprehension
A word steps promptly in as deputy.
With words 'tis excellent disputing;
Systems to words 'tis easy suiting;
On words 'tis excellent believing;
No word can ever lose a jot from thieving."
(Bayard Taylor's *Faust*.)

This is the element which in skilful hands determines for a moment the result of meetings, caucuses, assemblies. It is the emotional element, which is swayed by sentiment both false and true, by gesticulating oratory, and by implicit temporary confidence in the veracity and sound motives of its presumed leaders, which, therefore, "takes the specialists of the new Code persuasion by the tops of their heads and cuts their throats," but after all is cooled down by common sense, consciousness, and conscientiousness when left to itself. Such men are in the majority. They are the waves of the ocean, always changing, now smooth and smiling, then turbulent and raving; and still always the same, steady in their general effects, now and then a disturbance, and an injury, but always the internal source of healthful development. We never cease to bless the ocean, even when it is doing its temporary worst. Let us, therefore, not despair of the future peaceful and blissful development of the country or the profession in times of turbulent commotion.

What difference is left unabolished may be left to itself until acrimony is soothed and bitterness replaced by kindness. Greater discrepancies than these have been wiped out. When the actions of men will be weighed, their opinions in regard to dogmatic utterances will be disregarded. When deeds are counted, let creeds be tolerated. But let us have patience, all of us; great improvements in the universal conscience do not take place by hard fighting and refuting. Lecky is right when he says that the greatest errors cannot be annihilated; it takes time for them to fade out.

In the face of the explanatory declaration passed in New Orleans, which in its main aspect, I take it, endorses the New York State Society and the spirit of the New Code, the majority of those present in the meeting of the American Medical Association were guided into believing that they must protect a sacred code from infidel invaders. The main complaint was that new code men had been given offices in the organization of the International Congress. On page 101 of *The Journal of the American Medical Association* you will find the following complaint: "Directly upon the threshold of the most important part of their work a majority of the original committee practically ignored all allegiance to the Medical Association, and, assuming an entirely independent attitude, at once placed in the front of their ranks . . . one who was well known to have repudiated the National Code of Ethics." And in a voluminous circular addressed to State and county medical societies, composed almost exclusively of editorials of *The Journal of the American Medical Association*, and signed by the permanent Secretary of the Association and four other gentlemen, the following language is used: "The editorials of *The Journal of the Association* . . . present the case (the differences in regard to the proposed organization of the International Congress) so clearly that there can be no doubt of the duty of the friends of the Association, or of the animus of its enemies. We feel assured that your Society will endorse the action of the Association, and stand firm in support of the Code of Ethics."

It is, however, fairly understood by this time that the war of the codes is over. In fact it has always appeared to unsophisticated people that the fighting about the code was not reciprocal at all; for when the New York State Society had settled its code question to its satisfaction, and that of the country societies in affiliation therewith, it appears that in them and by them, the subject was not mentioned again except on strong provocation. You remember that it took a great deal of emphasis to relieve even this Academy of the proffered dispute. The code question is dying a great deal more easily than the bloody shirt disappeared from the politics of the country. If it is puffed up as the pivot of the organization of the International Congress, everybody is perfectly aware that this is either a pretext or a grave mistake. Europeans who were not afraid of admitting laymen and homœopathists, expected to meet, if ever they would consent to cross the Atlantic for an International Congress, the American medical profession. No International Congress must be caught in domestic quarrels, or audaciously kidnapped by a society or a party, or the faculty of a medical school.

We are presenting a sad spectacle. In our first attempt at welcoming the medical world to our shores we have failed. The humiliation connected with this fact we have to submit to; to trace it to all its causes I cannot undertake here. The least we can do is to admit it; if the task we hoped to accomplish was too much for us, let us try to prepare for the future by attending to those duties of our own which we can perform without hinderance or disturbance. The affairs of the Academy will require our undivided attention.

That I speak of no imaginary evil we all know too well. What I said a few months ago of the growing tendency of a few to make the public acquainted with their merits and accomplishments through the columns of the secular press was considered timely, and met with the appreciation of many members of the profession, both old and young, here and elsewhere. I mean to deserve the respect of my peers and superiors in the profession by again directing your attention to the fact that the penny-a-liners of the daily press are being utilized in the interest of, and by weak-kneed brothers who cannot stand on their own legs, who mistake cheap notoriety for reputation, and the grin of derision for the smile of approval. The more power is concentrated in commerce, the greater the prevalence which is conquered by trade; the more rampant the spirit of grasping egotism which is pathognomonic of modern industrial pursuits, the more is it the domain of the liberal professions to approximate their aims to an ideal. Let us not forget that learning by heart the action of medicines, or the working of articulations, or the proper use of an instrument, does not exhaust the possibilities of a medical man. The physician requires all that, but beyond that all the characteristics of a man of principle and intellectual and moral culture. Neither can be inculcated by the demands of old or new codes. Still, as a corporation and a profession, we are responsible for the existence of these qualities in our members. It is true we cannot supply ideals to order, nor can we make those whose eyes seek the mire, raise their brow

Digitized by Google

to the skies. But such as find it difficult to develop those qualities spontaneously, must be taught and aided in acquiring them.

As far as I am concerned, I hope there will be no occasion again to refer to the same subject during my term of service. If there be, I shall repeat my warning. For I take it for granted that when you elected me to the highest office in your possession, you did so both in the belief that your candidate would have opinions and principles of his own, and on the condition that he should do his full duty.

(*To be concluded.*)

MEDICAL SOCIETY OF VIRGINIA.

Sixteenth Annual Session, held at Alleghany Springs, Montgomery Co., Sept. 15, 16, and 17, 1885.

(Specially reported for THE MEDICAL NEWS.)

(Concluded from page 391)

DR. R. C. POWELL, of Alexandria, presented some

CLINICAL NOTES ON CARCINOMATOUS AFFECTIONS OF THE DIGESTIVE ORGANS; THE UNRELIABILITY OF GASTRIC SYMPTOMS AS EVIDENCES OF GASTRIC PATHOLOGY.

He related some cases to illustrate two points of diagnostic importance: (1) unreliability of gastric symptoms as evidence of gastric disease; and (2) the great value of cachexia as corroborative evidence of malignant disease. He regards the cachexia as a more certain sign of cancer than the presence of a tumor. As to treatment, the indications are to sustain strength and to relieve pain. A judicious selection of food is necessary if the stomach be involved.

DR. M. A. KUST, of Richmond, presented a paper on *The Etiology of Zymotic Diseases.*

PROF. M. L. JAMES, of Richmond, then read a paper on

DYSPEPSIA WITH NEURASTHENIA AND SOMNOLENCE.

He referred to the fact that dyspepsia is one of the most frequent causes of neurasthenia, from the double effects of interfering with digestion and producing a kind of shock to the nervous system. However, those cases which are marked by the severer forms of neurasthenia with some somnolence are usually in part a result of other causes; among which he cited, excessive labor, especially mental, excessive use of stimulants, dissipated habits, and abuse of the sexual organs. He noticed the fact that the indigestion and the neurasthenia react upon each other, but the neurasthenia having been produced largely by the indigestion, intensified the latter, and that, in the treatment, the digestion should be maintained in the most perfect condition, and all causes which produce and increase the neurasthenia should be removed, so that the digestive process may secure the greatest degree of innervation. While it is true that digestion is a chemical process, which may be conducted in retorts, it is nevertheless an intensely vital one. The nervous system has a large influence in maintaining or impairing the efficiency of digestion, and to that end he indicated that one of the most important measures of treatment is to secure the patient ample, undisturbed, and refreshing sleep. The food should be selected with reference to its ease of digestibility, and at the same time its capacity for sustaining nutrition, especially that of the nervous system, and hence that there should be a due regard to its richness in the phosphates. He said that inasmuch as the chief difficulty in this morbid association occurs with dinner, it is a matter of great importance that the nervous system shall have a period of rest, lasting from half an hour to two hours, according to the severity of the case, before partaking of this meal, in the recumbent position, accompanied by sleep, which is a habit that may very soon be acquired.

He stated that while stimulants, especially those which stimulate the cerebral lobes, such as caffeine, are suitable for single occasions, they are not suitable for habitual use and the final cure of the morbid concatenation. And for that reason he suggested the use of such tonics as quinine and strychnia in tonic doses, and the phosphates with a very limited amount of caffeine, either taken in the form of an alkaloid or else in a limited amount with tea and coffee. He indicated the following as a convenient formula for many of these cases, which he used with the best results:

℞.—Quiniæ phosphat. . . .	gr. xvj.
Strychniæ phosphat. . . .	gr. ½.
Acidi phosphoric. (50 per cent.)	♏ xx.
Caffeini citrat.	gr. xvj.
Aquæ puræ	ʒ vij.
Glycerinæ puræ,	
Spts. vini rectificat. . . .	āā ʒss.
Tr. cardamomi co. . . .	ʒj.

Misce secundum artem.

S. One or two teaspoonfuls immediately before or after breakfast and dinner, to be repeated when necessary every hour or two till the nervous depression is relieved, or every half hour till one or two doses are taken, if this depression be great.

For cases in which the digestion is so enfeebled, that the foods ordinarily in use can not be tolerated or digested by the stomach, he advised the use of concentrated animal foods in a fluid form and especially foods predigested by the use of pancreatine, pepsin, and diastase. And where the condition of the stomach is so extreme that food will not be tolerated by it, these forms of food should be administered by rectal alimentation.

AFTERNOON SESSION.

THE REPORT ON ADVANCES IN HYGIENE AND PUBLIC HEALTH

having been called for, Dr. Edwards announced the sudden death of the reporter, Dr. Wm. H. Coggeshall, of Richmond, on September 7th, just as he had finished his paper. By request Dr. Edwards read the paper.

After referring generally to the new inventions, and revivals of old methods intended for the use of the profession and public, in the matter of disinfection, especially in view of the threatened invasion of Asiatic cholera, the reporter had been able to find no subject of greater interest to himself, and he thought to the members generally, for a paper under this head, than

THE RECENT EPIDEMIC AT PLYMOUTH (PA.) AND THE LESSONS IT TEACHES.

He gave in full detail the particulars, and drew the following lessons from this peculiar epidemic:

Digitized by Google

1. That from an exceedingly small and apparently trivial source of infection, danger to a large number of persons may arise in the course of a zymotic disease.

2. That whatever doubt could previously exist in the mind of any member of the profession regarding the power of previously pure running water to become an active carrier of typhoid infective germs, has by this epidemic been entirely dissipated.

3. That the uncleanliness and non-sanitary condition of a town or city prolong, in the direct ratio of their extent, the stay of an endemic or epidemic in such place.

4. That during a typhoid epidemic—and especially in its early stages—cases of the disease may, and do, occur, where the patient, having proper sanitation at home, receives the poison germs into the system by the simple imbibition of water containing such organisms elsewhere than at home, without his or her knowledge or suspicion.

5. That a town cannot afford to remain in an uncleansed condition, however remote danger from zymotic disease may otherwise appear, as such uncleanliness is a direct invitation to certain contagious and infectious diseases to establish a firm foothold in that place.

6. That a typhoid epidemic occurring in a city, once brought into existence from any cause, is easily enlarged and more fully developed by neglect of well-known and easily effected individual and municipal sanitary measures.

7. That the water supply of a town or city—notwithstanding the safeguards commonly thrown around it by the municipality—can easily be transformed, suddenly and unexpectedly, by contamination, into a poisonous condition for the uses of a community, from a source at once remote and individual.

8. That careful and thorough disinfection of the excreted matter—both liquid and solid—voided by a typhoid fever patient, is of the utmost importance to the health of the surrounding community, whether in city or country, but owing to lack of proper sewerage facilities, especially so in the latter.

9. That the physician practising in a rural district which is in any manner remotely or directly connected with the water supply of a corporation, should exercise more than ordinary precaution to see that such water supply is placed in no danger of receiving contamination from his patients, either actively or indirectly.

10. That although it has been the custom in past years to look upon the water of city wells in general as far more liable to hold contamination from poisonous organisms than water furnished from reservoirs, yet the "Plymouth epidemic" has shown that a condition exactly the reverse may exist.

11. That to eliminate all possibility of poisoning in this manner, from sewage or excretory matter, either through carelessness or ignorance, no human habitation should be allowed by law to exist near the source of a city's supply of drinking water.

Dr. Philip Taylor, of Richmond, read a

RÉSUMÉ ON OPHTHALMOLOGY AND OTOLOGY,

in which mention was made of the practical benefits to be derived from the use of jequirity in trachoma, with or without pannus, insisting upon the fact that chronic purulent conjunctivitis should not be present when jequirity is used. The late theory relative to the transmission of sympathetic ophthalmia, viz., by means of the intervaginal lymph spaces of the optic nerve, was given, and conclusions concerning the septic poison being conveyed by the ciliary nerves from the diseased or injured eye to the unimpaired organ—the once popular theory—were rendered.

Cocaine received notice as one of the most important strides that had been made in ophthalmology for many years. Its uses and effects were dilated upon. Numerous operations were referred to, that had been brought before the profession during the past year, notably one for pterygium, by Dr. Prince, of Illinois; another for evisceration of the eyeball as a substitute for enucleation, also one for the transplantation of the cornea, in case of considerable opacities rendering iridectomy impracticable. The danger of performing the operation for internal strabismus in the young, and making the correction absolute, pointing out the fact that as maturity comes on insufficiency is quite apt to follow, causing external squint. In otology some recent preparations for purulent ear troubles were discussed, especially peroxide of hydrogen. New style Eustachian catheters, and the method of using bougies for dilating the Eustachian tube, were approved. Connection between diseases of the teeth and ear was referred to, and statistics rendered, showing that sympathy existed between these parts.

Dr. Joseph A. White, of Richmond, then offered some

PRACTICAL REMARKS AND SUGGESTIONS IN REGARD TO DISEASES OF THE EAR, THROAT, AND NOSE, WITH REPORTS OF A FEW CASES.

Neglected suppurative middle-ear inflammation, he said, has ended fatally. To relieve the pain, use local leeching and warm applications, and drop into the ear a twenty per cent. solution of muriate of cocaine with sulphate of atropia, and give anodynes internally. He is satisfied cocaine acts as an anæsthetic upon the drum membrane, notwithstanding the contrary statements of some writers. Muriate of pilocarpin and sulphide of calcium ought to be given during the stage of exudation, but the use of pilocarpin in the ear during aural complications of the exanthemata should be carefully watched, for fear of causing paralysis of the heart. If pain is unabated and the tympanic membrane bulges, tap the posterior inferior quadrant, and, by aid of an air-bag, empty the tympanum. Keep the ear clean by frequent syringing with carbolated or borated solutions of sodium bicarbonate, and use Politzer's air-bag daily, so as to keep the Eustachian tube free. If pain persists, continue cocaine solutions, but now leave off the atropia, which is dangerous when the tympanic membrane is opened. Dust the drum once or twice a day with powdered boracic acid. Disease of the mastoid cells and of the brain is a frequent result of middle-ear diseases, and complete deafness is common. During scarlet fever, the earliest signs of ear complaint should attract attention. Topical leeching and sulphide of calcium internally, will often arrest threatened mastoid disease. Freely incise to the bone, or even trephine, if redness and pain continue.

DR. CHARLES M. SHIELDS, of Richmond, read a report of a

CASE OF TRACHEOTOMY FOR LUPUS OF THE LARYNX AND DIPHTHERIA.

He said that only about a dozen cases of lupus of the larynx are mentioned in the text-books. His patient was a retired physician, aged about 55 years, who had suffered from hoarseness and pain in swallowing, but at no other time, for more than a year. His voice was reduced to a whisper, and he had dyspnœa. The laryngoscope showed general redness and congestion, with so much swelling of the right vocal cord and ventricular band as to render them undistinguishable. This growth was covered with small, pale, fleshy tubercles, and having superficial ulcerations between them. The gentleman never had syphilis, and there were no signs of phthisis, nor was carcinoma hereditary in the family; and, hence, all of these usual causes of laryngeal growths were excluded. The diagnosis of lupus was strengthened by the fact that he had had two or three suspicious small ulcerated growths upon his face and arm, which would not heal until they had been excised, and which were most probably the skin manifestations. He first took iodide of potash, and afterwards arsenic, and iodoform and bismuth were applied locally; but the lupus progressed, and the swelling and ulceration increased, until, seven months from the time he presented himself, his occluded larynx threatened suffocation. Both sides of the larynx were immensely swollen and covered with the pale elevations and ulcerations, and the aperture of the glottis was not visible. Tracheotomy was performed without chloroform, but the operation was rendered long and tedious by his short, thick neck, and the pushing down of the trachea by the enlarged larynx, so that very little space was left for the incision, and an extra long silver canula had to be used. Great relief followed the operation. He soon learned to remove, clean, and replace the entire tube without difficulty. He was doing well the following summer.

DR. SHIELDS also reported a successful

TRACHEOTOMY FOR LARYNGEAL DIPHTHERIA

in a girl three years old. After the fifth day, the amount of membrane in the larynx increased rapidly, and threatened death by suffocation. She was being treated with iron, quinine, and large doses of whiskey. The room was kept filled with vapor of lime. Tracheotomy was not consented to by the parents until the eighth day, when she was cyanosed, and the sternum was indrawn, and she was thought to be dying. The usual incision was made and the tracheotomy tube introduced, but all efforts at breathing stopped. Artificial respiration was resorted to, and the tube withdrawn again, when a piece of tissue in the lower angle of the wound was drawn out by the forceps, and proved to be a perfect cast of the trachea two inches long. The canula was again put back, and artificial respiration being continued, she began to make efforts to breathe. After this she did well for two days, when she breathed with more difficulty, until she coughed up through the tube another cast of the trachea. The edges of the wound were covered with diphtheritic membrane. No air passed through the larynx for nearly a week after the operation, and the tube had to be kept in three weeks before she could breathe comfortably through the natural channel. She made a good recovery.

DR. L. ASHTON, of Falmouth, made *A Plea for Tracheotomy in Croup*.

EVENING SESSION.

DR. J. S. CONRAD, Superintendent of Matley Hill Sanitarium, near Baltimore, Md., by invitation, read a paper on the

PSYCHOLOGICAL ASPECTS OF SUICIDE,

of which the following are the conclusions:

1. Suicide increases with the advance of civilization, and is but little known in the savage state of men.

2. The act is an intelligent one (?), done with a full consciousness of the act, as shown by the method of execution, whether by the sane or insane.

3. That suicide is done always for the purpose of escaping an evil, and for the benefit of the felo-de-se, whether by sane or insane.

4. That it is a voluntary act (?), whether by sane or insane.

5. That it is an emotional act, whether by sane or insane, however deliberately planned and executed, since deliberation enters into the mind of both mental states.

6. That delusions are not essential to the distinction as to the sanity or insanity of the suicide, since authorities affirm that delusions are not essential to the proof of insanity.

7. That suicide is rare in the first class (*Insanity*, by Maudsley), viz., intellectual or ideational insanity; but does occur in the vast majority of the second class, or affective or emotional forms of insanity.

8. Query. Is suicide an intellectual act, notwithstanding the intelligence exercised in its execution? Or is it an emotional act *per se*, since we have seen that the emotional part of mind dominates the ideational centres, and perverts the intellect into becoming its humble servant?

9. Does moral depravity satisfactorily account for it, when we have seen that moral depravity is a factor of both sane and insane?

10. That in doubtful cases of the sanity or insanity of the felo-de-se, very great caution is necessary in making up a just judgment as to the one or the other.

DR. W. R. CUSHING, of Shawsville, reported a case of

PREMATURE LIVE BIRTH WITH THE MEMBRANE INTACT,

in which the child lived some sixteen hours. He called attention to the effect that the possibility of such births must have upon the lung-test in deciding whether a child was born alive or not. Persons heretofore tried for infanticide have been admitted to be innocent whenever it could be proven that the child had never breathed. But in such a case as he here reported, the child could have been deliberately killed after being removed entirely from the mother, and still the condition of the lungs not only would not have testified against the party accused, but would have been admitted as conclusive evidence of innocence.

DR. WILLIAM C. DABNEY, of Charlottesville, read a paper on the

PHYSIOLOGICAL AND THERAPEUTICAL ACTION OF ANTIPYRIN.

In typhoid fever, two doses of ʒss each, at an hour's interval, usually produce a fall of two or three degrees

Digitized by Google

which lasts from six to twelve hours, but the course of the disease does not seem to be modified by it, except that it soothes the patient, and he drops off to sleep. It lessens delirium to a considerable degree. It acts favorably upon the nervous symptoms generally, and it also cleans up the tongue. It is generally conceded to be useless in remittent. In puerperal septicæmia it gives good results, reducing the fever to normal temperature from 105°. Sixty grains in two cases caused a semi-comatose condition, and symptoms resembling those of carbolic acid poisoning. In scarlet fever, favorable results are reported, especially delaying the appearance of the eruption. Some say that in phthisis, it has given better results than all other antipyretic remedies combined. Others think its desirability in phthisis is questionable. It should be given with great caution in this disease for fear of inducing a collapse. Agaricine or atropia prevents its producing too much sweating. It acts unfavorably in pregnant women. The unpleasant effects of antipyrin are collapse and an eruption much like that of measles. The dose of antipyrin differs according to the disease. In phthisis from eight to fifteen grains, repeated every four to six hours, is sufficient. In typhoid fever, pneumonia, and the like, it has been recommended to give two doses of thirty grains each, at an interval of an hour, and an hour later still, give fifteen grains more; but more recently excellent results have followed doses of ten to fifteen grains every three or four hours. In children, the dose is a grain and a half for each year of the child's age. It may be given hypodermatically in dose of from ten to fifteen grains, or by enemata in doses of from forty to sixty grains. When used as a suppository, it is said to have an excellent effect on hemorrhoids.

Adjourned.

CORRESPONDENCE.

THE REPORT OF THE MEETING OF THE COMMITTEE ON THE INTERNATIONAL MEDICAL CONGRESS.

To the Editor of THE MEDICAL NEWS.

SIR: The following letter was addressed by me to the Secretary of the Committee on the International Medical Congress:

CHARLESTON, September 16, 1885.

TO DR. JOHN V. SHOEMAKER,
Secretary of the Committee of Arrangements for the International Medical Congress.

DEAR SIR: In the *Journal of the American Medical Association* for September 12th, there is a publication, under your signature as Secretary, of what is styled a "*Report of the Committee appointed to arrange for the meeting of the International Medical Congress in America in 1887.*" As a member of the Committee of Arrangements, present during the session of the Committee held in New York City on the 3d and 4th of September, I am not aware that you were instructed or authorized to make any other report than such a one as naturally pertained to your duties as Secretary. The correct and full report of the minutes of the meetings of the Committee it is most surely your duty to prepare, and the publication of such minutes, unless specially interdicted by vote of the Committee, seems to me to have been in order. Your "report," as published, is not the minutes of the meeting, nor does it fully or fairly represent these, as far, at least, as relates to the meeting in New York. As a member of the Committee, I think it due to the Committee, and to the profession of our country, that the full action of the Committee, which carries with it the animus or real intention which determined its work, should see the light of day. You will, therefore, pardon me if I appear intrusive, when I ask you to inform me if it is your intention to publish a detailed report of the minutes of the late meeting of the Committee, held in New York, on the 3d and 4th of September.

Very respectfully, R. A. KINLOCH,
Member of the Committee from South Carolina.

This letter was forwarded as far back as the 16th of September, but has failed to elicit a reply. I am, therefore, forced to conclude that I shall not have the courtesy of a reply, and that there will appear no official report of the minutes of the meetings of the Committee on the International Congress, notwithstanding the interest manifested in this matter by the profession. As a member of the Committee, however humble, I am not ashamed of any views I have expressed, or of any action I have taken. Nor do I desire to bear the sins, either of omission or commission, or to claim the fruits of the good work that may be the outcome of this body.

I accepted a position on the enlarged Committee created by the action of the American Medical Association at its late meeting in New Orleans, not because I approved of the action of the Association in its mode of dealing with the work of the original Committee of Eight, but because I recognized the obligation to serve the Association, and indulged the hope of sustaining a spirit of harmony, which I feared might be interrupted by the diversity of opinions coming of a too ponderous Committee of Arrangements.

That the Committee could best discuss the respective merits of men suggested for filling important offices in the Congress by sitting with closed doors, was an argument of some force; but it will scarcely be urged by scientific men, that the shortcomings of the body, the conduct and ruling of its officers, the time of its discussions, the policy of its actions, the views and the animus of its individual members should be guarded in the same way, and known only to unwritten history. Why then, I ask, this suppression of this much of the proceedings of the meetings? And by what authority does the secretary of the body undertake to report in the way that he has done? As I was absent from the meeting for a brief period prior to its adjournment, it is possible that the Committee may have instructed the secretary as to his course of action. If so, I can only at this late date raise my voice in condemnation of such a policy.

All the acts of the Committee were of course the result of a majority vote, and so far as it has worked for the supposed advantage of the Congress I prefer to say nothing. I trust that its action will prove satisfactory. But, while majorities rule, minorities have certain rights, and among these is the right to be put upon record. As an independent member of the Committee, I do not intend that my rights shall in all particulars be ignored. The verdict of a noble profession is something that I hold of inestimable value, the approval or disapproval of a court so constituted I am willing to accept, provided

Digitized by Google

such is based upon my individual merits or demands. There was with me during all my connection with the Committee the proud desire to promote harmonious action, and thus save the American Medical Association and the profession of our common country from dissensions which threatened their well-being, if not the vital interests of both, and which already have, in part, subjected us to the censure, if not the ridicule, of our foreign brethren.

My first effort was at the informal meeting of the new members of the Committee at New Orleans, when I introduced the following resolution, after there had been presented several propositions, all of which, as seemed to me, were calculated to give some offence to the original Committee of Eight.

"*Resolved*, That the temporary officers of this meeting be instructed to correspond with the original Committee, expressing our desire to meet them at such time and place as may be agreed upon by the majority of the entire Committee."

The original Committee had worked laboriously and deserved something of the Association. If they had committed errors, they could not escape criticism, but with members of a common brotherhood, looking to scientific progress, criticism need not give offence. No proper feeling brother desired to add to the mortification or irritation which naturally attached to the members of the original Committee, when there were appointed additional members to their body, for the purpose of reviewing their work. The object of my resolution then was to try at the outset to establish friendly relations with the original body. The new members were merely *material added to this*. The original Committee was the fully organized body. It had not been abrogated, nor was its organization changed by the recent action of the Association. A cautious word from the temporary officers elected by the new members, if these officers were capable of appreciating the spirit of my resolution, was really the first and surest way of harmonizing the new with the old members of the Committee.

Drs. Flint and Billings were the officers of the Committee of Eight. They were also, now, the officers of the enlarged Committee, until that Committee should meet and decide to supplant them. It rested, then, with these gentlemen to call the Committee together; *the duty pertained to none others*.

Some confusion arose in regard to the function of the Committee as enlarged, and as to the attitude of the original Committee to the Association. The members of the original Committee naturally desired time for conference and careful conclusion. This should have been accorded them. But, unfortunately, the temporary officers of the meeting at New Orleans incorrectly estimated their position, and failed to perceive that harmony was necessary for professional unity, and unity essential to the scientific interests of the Congress. The function of these temporary officers had ceased after they had carried out the instructions given them by my resolution. And yet they magnified their recent position, forgot the spirit of their instructions, ignored the existence of the President and Secretary-General of the Committee, transferred the headquarters of the Committee from Washington to Philadelphia, called for the vote of all the members of the Committee, as to time and place of meeting, and resolved to meet at Chicago on the 24th of June. Strange to say, it does not seem to have occurred at that time to any of the members of the Committee, besides myself, that these temporary officers of the New Orleans meeting had committed a bold and unjustifiable act. This was painfully evident to me, however, for I saw at once that the letter and spirit of my resolution had been trampled under foot, and I lost hope in the success of the Congress.

The call for the Chicago meeting, made in the name, or under the authority, of my resolution, seemed to be accepted by the Committee as right and proper. I alone protested and refused to vote. My protest was sent to the *Association Journal*, but reached the Editor too late, as he informed me, for the issue which immediately preceded the time of meeting of the Committee. As a final effort, I wrote an earnest letter to Drs. Cole and Shoemaker, and insisted that my views should be presented to the meeting in the event of my failing to be present. The meeting was held at the time specified, *but my letter or views were not mentioned*.

The result of the Chicago meeting is known to the profession. I was unavoidably absent, and subsequently shared only in the general regret that the character of the work done necessitated its reconsideration. The meeting at New York was called partly for this purpose. I was present, and at the earliest moment I claimed the privilege of having recorded upon the minutes the letter which I had written to the *Association Journal*, and which explained fully my views as to the unjustifiable action of the temporary officers in calling the Chicago meeting. I also made the public statement as to the failure of these officers to bring my letter before the Committee at Chicago. Through the failure of the Secretary to publish the minutes of the New York meeting my views were again suppressed, and hence the unpleasant necessity of having now to justify my action. It is due to the officers of the meeting to say that they disclaimed any intention of purposely suppressing my letter at Chicago, but, at the same time, they offered no very satisfactory reason for their singular omission.

The next matter which duty to myself compels me to notice has reference to the alteration of the rule, as adopted at Chicago, determining the American membership of the Congress. This rule had been fixed, as was claimed, *in obedience to the voice of the American Medical Association*, so as to restrict the membership on ethical grounds. The determination of a few adroit members of the Committee was now to undo what had been done, and in their own peculiar way. By management more suitable for a political than a professional or scientific body, and which I will not now comment upon, the rule, as prepared for presentation to the Committee, which it was claimed opened the Congress to all members of the regular profession, was finally brought before the body. I asked the gentleman who had introduced the subject whether, under the proposed rule, all members of the Congress would be alike eligible for office, and whether he would favor the election of any member of the profession simply upon his merits, or whether there was not a mental reservation upon the part of those suggesting the change by which, upon ethical grounds, certain members would be members merely, and debarred from holding office.

Digitized by Google

The answer came, that in accordance with the "resolution" of the American Medical Association certain parties must be refused high position. I asked for the reading of the "resolution" referred to. I wanted to know whether the Association had ever drawn any such fine distinction, opening the membership to all, but restricting the distribution of honors. It turned out that there was no such resolution ever adopted by the Association. I then maintained that if the Association and its implied sentiment were to guide the Committee upon this occasion, it was more consistent to hold on to the Chicago rule than to accept the amendment as now proposed. I offered to support the amendment with all my heart if this was honestly offered, and if the mover would amend it further by stating that all members were equally eligible for office, or if he would agree to show that, practically, all were eligible by voting for men on their merit and regardless of ethical standing. If this was declined, I insisted I could not vote for the amendment, for I would not pretend to offer bread and give a stone. My proposition was not accepted, but the new rule was adopted without my vote, and *all in the name of the Association.*

One other point deeply interested me, and determined my rejection of office. It was well known that the rule, as adopted at Chicago, which restricted the membership of the Congress upon ethical grounds, had occasioned the resignation or withdrawal of many of the best and strongest men in the profession, regardless of their views on the code question. A conciliatory spirit on the part of the Committee, as now newly constituted, was of supreme importance, for we could ill afford to do without so many of the good minds of the country. Under the resolution of the Association, the Committee had power to fill all vacancies occurring in its own body, and to appoint officers to the Congress. This was regarded as implying the right to accept resignations from positions which had been previously filled by the original Committee of Eight, or by the present enlarged Committee at its meeting in Chicago. The work of filling vacancies was being pressed on, *when the Committee had no knowledge of resignations except the mere verbal report of the Secretary.* The idea seemed not to have occurred to any one that all letters of resignation should be read before the Committee, or that courtesy and justice to the parties sending such letters demanded such reading. It looked as if the officers of the Committee, and not the Committee itself, were, to use a trite expression, "running the machine." I desired, naturally enough I thought, to know the reasons for the resignations which had been sent in to the Secretary, and therefore asked for the reading of the letters. We were surprised to learn from the Secretary that the letters had been left in Philadelphia, and, besides, that they were so numerous that there would scarcely be time for their reading. I nevertheless urged that the telegraph should be used to insure the letters' reaching us in due time. The Secretary finally arranged to send a special messenger for the papers, and they arrived in time for the second day's session. I now again called for the reading of the letters. They were, under resolutions offered in plea of press of business, twice put upon the table to await convenience. But at last I succeeded in having a few letters read. I heard enough to conclude that if the obstructions to membership, and to the honors of the Congress were really removed, and a proper spirit of conciliation evidenced by the Committee, most useful men could yet be saved to the Congress. Meantime the work of filling the so-called vacancies in the most important offices had continued without any questions as to the acceptance of resignations. The spirit of vindictiveness (I regret to have to use the term) under the presumed offence given by the parties who had proposed to withdraw, seemed to me to be irrepressible, so I could not consent to occupy the position of Vice-President in the Surgical Section which had been assigned me, both by the original Committee and the present one. As an unavoidable engagement precluded my presence at the meeting of the Committee towards the close of the session when the list of Vice-Presidents of the Sections was up for consideration, I left with a member of the Committee my written reasons for declining office. These were read, but of course suppressed with other portions of the minutes.

In conclusion, let me state that I think it not unlikely that some of my professional brethren will charge me with egotism, and condemn the course I have pursued in thus publicly announcing personal grievances. This I shall regret, but I apprehend there will be many who will agree with me that personal grievances may be blended or indissolubly connected with the interests of the whole profession. Had I not regarded those which I have here recorded as of that category, I should never have adverted to them.

One word in relation to the gentlemen constituting the enlarged Committee. Many of them are my personal friends. I dispute not the right of individual opinion. I claim no superiority over my brethren, but my own convictions are strong and sincere. There are many of the Committee whom I know to be as conservative as I claim to be. I feel grateful to some for the support I received while striving to modify the determined policy of the majority. I intend no offence to the Committee as a whole, unless it be an offence to offer the assurance that now and ever I do not mean to allow my individuality to be destroyed.

R. A. KINLOCH,
Member of Committee from South Carolina.

CHARLESTON, Oct. 1, 1885.

THE DANGER OF DOUBLE OVARIOTOMY.

To the Editor of THE MEDICAL NEWS.

SIR: In a paper which I have just read, by Professor Ransohoff, I find the following sentence: "It must be remembered in this connection that the removal of the second ovary adds very much to the danger of the operation. While from single ovariotomies Wells and Koeberlé show a mortality of 22 per cent., the former in eighty-two double ovariotomies has lost 34 per cent., whereas 51 per cent of those operated on by Koeberlé, for bilateral ovarian disease, have died." Would you allow me to point out that this mortality has nothing whatever to do with the fact of both ovaries being removed, but is entirely due to the fact that the clamp was the means by which the pedicle was treated. This is completely established by a recent publication of mine in *The Provincial Medical Journal* for the 1st September, in which I published a series of 112 consecutive cases of ovariotomy without a death. This included 49

Digitized by Google

cases of cystoma of one ovary; 21 cases of single parovarian cystoma, and 35 cases of removal of both ovaries for cystoma, and all these without a single death. This, in the whole of my previous experience of abdominal section now amounting to over 1200 cases, shows conclusively that all the disasters that we had, and all the irregularities in our results, were due to the clamp, and to the clamp alone. If an abdominal wound could not be accurately closed when one pedicle was dragged outside, it stands to reason that if there were two pedicles clamped, the likelihood of accurate closure was much diminished, and therefore the chances of death were more than doubled. This was the fact in Sir Spencer Wells's practice. But the moment the clamp was given up the reduction of mortality was enormous, and not the slightest difference is discernible between removal of two ovaries and removal of one. This fact must very materially modify the conclusions which are enunciated in Professor Ransohoff's paper.

I am, sir, yours, etc.

LAWSON TAIT.

BIRMINGHAM, September 20, 1885.

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

PROFESSIONAL COMPENSATION.—A propos of the Hoyt will case that is being summed up before the Surrogate, it is stated upon good authority that the two "experts" who appeared for Miss Hoyt, the contestant, demanded respectively five and ten thousand dollars for their services, and were paid. Despite this windfall, bad luck seemed to follow, for one tried to shoot his wife, and is now in an insane asylum as a patient, and the other died a few weeks afterward. The case was "run" in the beginning by one Aaron Kahn, who left the congenial occupation of pawn brokerage for the bar. His bill, which was contested by his successor in behalf of Miss Hoyt, was $60,000, one item of $3000 being asked for one hour's attendance at the police court upon the occasion of Miss Hoyt's arrest.

POST-GRADUATE INSTRUCTION.—Both post-graduate schools are prosperous, and the promises held out are excellent. The Polyclinic has engaged Dr. F. S. Billings, an excellent pathologist, who has been with Virchow for some years and who is specially recommended by him to the school.

WASHINGTON.

(*From Our Special Correspondent.*)

YELLOW FEVER IN BOSTON.—It is officially reported from Boston, Mass., that four seamen of the steamer Craighill, which arrived at that port from Colen on the 24th ultimo, are now at Gallup's Island Hospital with well-defined symptoms of yellow fever. Two of the patients are quite sick, but it is thought that all will recover. The captain died of the same disease on the voyage, but it was thought then to be malarial fever.

SMALLPOX IN FALL RIVER.—Several cases of smallpox were discovered on the 31st ultimo in Fall River, Mass., and in a small interior town in the State. The former cases have been traced directly to Canada.

OTHER RESIGNATIONS FROM THE CONGRESS.—Prof. H. Newell Martin, of Johns Hopkins University, has declined the Vice-Presidency of the Section of Physiology.

The *Atlanta Medical and Surgical Journal* announces that Dr. Robert Battey has resigned the Presidency of the Section of Gynecology.

GOVERNMENTAL INVESTIGATION OF CHOLERA IN SPAIN.—The President has issued an executive order directing Dr. E. O. Shakespeare, of Pennsylvania, "to proceed, under the direction of the Secretary of State, as the representative of the United States, to Spain and other countries in Europe, where cholera exists, and make investigation of the causes, progress, and proper prevention and cure of the said disease, in order that a full report may be made to Congress during the next session." Dr. Shakespeare sails to-day for Europe.

SURGEON-GENERAL HAMILTON.—It is announced that, in accordance with the request of the President, Dr. Hamilton has withdrawn his resignation as Surgeon-General of the Marine-Hospital Service.

PUBLIC OPINION ON THE CONGRESS ORGANIZATION.—The nominations of new presidents of the Sections seem, in the majority of instances, most extraordinary. We are near enough to the States, and familiar enough with American literature, to know pretty well the names of the leaders in the different departments of medicine and surgery, but of the seventeen names of chairmen of Sections, there are twelve absolutely unknown to us as representatives in their different departments. We ask of many, in blank astonishment, Who are they? What have they done? Where do they live? Truly the committee is sunk low when it must place such men at the head of important Sections in an international gathering. The contrast between some of the past and present nominees would be simply ludicrous, were it not painful.

The Association is determined to have the Congress, . . . but the leaders of the profession, and the workers who have made American medicine and surgery known here and in Europe, are not in it. The play will go on, but with Autolycus disguised as Hamlet. —*Canada Med. and Surgical Journal.*

As the welfare of the next International Medical Congress is not a matter solely of American interest, it seems to us to have been the bounden duty of individual men in Europe, and of the European medical press generally, to point out to what extent the organizers of the Washington Congress were departing from the established precedent, which, at any rate, has the argument of unbroken success in its favor. Dr. Davis complains that "the outside world" animadverted on the conduct of the American Medical Association before hearing both sides of the question. It may be replied to that complaint, first, that the action of the Association in disregarding the precedent of previous congresses, and monopolizing the conduct of the Washington meeting, was in itself a sufficiently accomplished fact to warrant any amount of European animadversion; secondly, that the subsequent action and arguments of the supporters of the Association have served rather to weaken

Digitized by Google

than to strengthen their case; and, thirdly, that it may be fairly assumed that the publication of European criticisms has had a measurable share in determining the new Committee of Organization to reconsider the whole question at issue during the present month, instead of deferring it, as originally intended, until next spring.

The objection still remains that the American Association, in taking charge of the Washington Congress, has introduced an innovation in the conduct of International Medical Congresses which is distinctly a matter for international criticism, and, in our deliberate opinion, for international condemnation.

But the further action of the American Association proves better than anything how wise has been the precedent of previous congresses and how ill-advised the attempt to break through it. One of the first acts of the American Medical Association when it got hold of the Congress was to insist that only those in accord with the National Code of Ethics should become officers of the Washington meeting, and as a result of this, many practitioners whose names are household words to us, and who are described by Dr. Noyes in a published letter as "the brightest lights and best workers in the profession," have been expelled from all official connection with the Congress. By that action, the Association at once broke the pledge deliberately given at Copenhagen, relit the old Code dispute, and attempted to score a point against the "new-coders," by enlisting against them the European visitors to the Congress. The full and final results of this policy have yet to be seen, but its first fruits, in the form of an electioneering manifesto published by the Association and sent to us by its representative, Dr. Shoemaker, are not particularly reassuring. This manifesto is headed, *more Americano*, "Pennsylvania sustains the Code of Ethics," and then follows a long list of practitioners in that State, all of whom profess to endorse heartily the action of the Association in raising the Code question. We need hardly add that this single official leaflet will do more to deter respectable English practitioners from taking part in the Washington Congress than all "the statements of certain medical journals and private parties in Philadelphia and New York," of which Dr. Davis so bitterly complains in his letter to Sir W. McCormac. In our opinion, the time has now come for the officers of past International Medical Congresses to meet together, and decide that, unless the pledge given at Copenhagen is kept, and all attempts to embroil the Congress in ethical disputes are unconditionally given up, the acceptance of the invitation to meet at Washington should be rescinded, and arrangements made to hold the Congress of 1887 in a country where the medical profession possesses greater solidarity.—*Medical Times and Gazette.*

It is evident that the work done by the Committee of the International Congress, at its secret meeting in this city, is an utter failure. The Committee has won over no new friends, but, on the other hand, withdrawals continue to be made. We believe that there is no exaggeration in saying that there are not half a dozen representative men in the profession now who are prominently connected with the organization of the Congress.

The attempt to hold an international meeting under such circumstances seems certainly very wrong, while, if affairs continue on as at present, there will be a collapse of the whole affair before the year 1887. It is known that some of the gentlemen who withdrew from the Congress did so partly because they found that they could not get coöperation at home or abroad; they could not organize Sections so as to secure successful work, and this difficulty must steadily increase.

Beyond all this, the obstinate conduct of the gentlemen who are trying to arrange the Congress on American Medical Association principles is arousing a constantly stronger indignation among the profession at large. It is clearly seen that their perversity and disloyalty are bringing discredit upon American medicine. —*Medical Record.*

The body which calls itself the Organizing Committee of the International Medical Congress of 1887, has, we are sorry to see, refused to adopt the conciliatory policy which alone can make the Washington Congress a success. It met at New York on the 3d instant, and though all reporters were sedulously excluded, enough has leaked out to assure us that the letters of the President and Secretary of the London Congress, and the articles of the large majority of medical journals, might just as well have not been written.

No attempt, it will be seen, was made to heal the differences that have been aroused in the profession by the revival of the Code question, and the American Medical Association still clings to its usurped position.

The more one considers the question, the more fatal do the objections appear to the principle of allowing a preëxisting medical association to play the sole part in organizing an International Congress. No medical organization whose aims are not purely and exclusively scientific can ever be truly representative of medical science. The men who are the real workers in the field of medical research, and who are therefore the only proper representatives of the profession in a scientific meeting like the International Congress, are hardly ever found playing a leading part in associations of a medico-political nature. Quite properly they leave such functions to those of their brethren who have business proclivities and time upon their hands. The latter class may be admirably fitted for the work of conducting a large medical association, but they are not qualified to greet on even terms the medical investigators of the world, and we doubt even if they are competent to decide who are best qualified to give that greeting. Thus there is always the risk, exemplified in the United States just now, of their dragging the political and ethical questions that are nearest to their hearts into competition with purely scientific questions. The only safe way of organizing a successful International Congress in any country is to leave it in the hands of the leading scientific men, who are known and acceptable, not only to the hosts of the Congress, but also to its guests. —*London Medical Times.*

Obituary Record.—Died, at his residence in Lancaster, Pa., on Thursday, October 1st, John Light Atlee, M.D, in the 86th year of his age.

Dr. Atlee enjoyed remarkably good health until about two years ago, when he had an attack of paralysis, from which he never recovered, and an attack of pleurisy a few days ago hastened the end.

Dr. Atlee was born in Lancaster on November 2,

Digitized by Google

1799, and was the son of Col. William Pitt Atlee, a Revolutionary officer. He was educated in Lancaster and Philadelphia; read medicine under Samuel Humes, and graduated from the University of Pennsylvania in 1820. After graduation he went to Pittsburg with the intention of settling there, but returned to Lancaster and began the practice of medicine in the latter part of the same year. The period of his practice has extended over a period of 65 years, and has been large and lucrative from the start. He soon became very successful in surgical operations, and in this branch of his profession his reputation was widespread. Dr. Atlee's operation for double ovariotomy in 1843 was the first in the history of medicine, and the patient is still living in this city in good health.

He was one of the founders of the Lancaster City and County Medical Society in 1843, and twice served as president. In 1848 he assisted in organizing the State Medical Society, and became its president in 1857. He was also one of the organizers of the American Medical Association in Philadelphia in 1847, was elected Vice-President in 1865, and President in 1882. He was Professor of Anatomy and Physiology in Franklin and Marshall College for many years; was School Director for 40 years; was President of the Board of Trustees of the State Lunatic Asylum at Harrisburg; was Associate Member of the College of Physicians, Philadelphia; was elected Honorary Fellow of the American Gynecological Society in 1877, and was trustee of numerous public institutions. He was a valued contributor to the *American Journal of the Medical Sciences*, and other medical periodicals.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 29 TO OCTOBER 5, 1885.

MCPARLIN, T. A., *Colonel and Surgeon.*—Directed to transfer his duties and the public funds, for which he is accountable as Assistant Medical Purveyor, to Captain Henry Johnson, Medical Storekeeper, who will, in addition to his present duties, temporarily perform the duties of Assistant Medical Purveyor, N. Y. City.—*S. O. 223, A. G. O.*, September 29, 1885.

CALDWELL, D. G., *Major and Surgeon.*—Ordered from Fort Laramie, Wyoming Territory, to Fort D. A. Russell, Wyoming Territory.—*S. O. 97, Department of the Platte*, September 28, 1885.

BARTHOLF, J. H., *Captain and Assistant Surgeon.*—Ordered from Fort Ringgold, Texas, to Fort McIntosh, Texas, for duty as Post Surgeon.—*S. O. 125, Department of Texas*, September 28, 1885.

BRECHMIER, Louis, *Captain and Assistant Surgeon.*—Ordered from Fort D. A. Russell, Wyoming Territory, to Fort Laramie, Wyoming Territory.—*S. O. 97, Department of the Platte*, September 28, 1885.

MACAULEY, B. A. B., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort A. Lincoln, Dakota Territory, and ordered for duty at Camp Poplar River, Montana Territory.—*S. O. 105, Department of Dakota*, September 21, 1885.

KREUDLER, WM. L., *First Lieutenant and Assistant Surgeon.*—When relieved from duty at Camp Poplar River, Montana Territory, by Assistant Surgeon Macauley, to report to commanding officer Fort Snelling, Minnesota, for duty.—*S. O. 105, Department of Dakota*, September 21, 1885.

WALES, P. G., *First Lieutenant and Assistant Surgeon.*—Relieved from temporary duty at Boise Barracks, and ordered for duty at Fort Cœur d'Alene, Idaho Territory.—*S. O. 160, Department of Colorado*, September 21, 1885.

EWING, C. B., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort Stanton, New Mexico, and ordered for duty at Fort Lavenworth, Kansas.—*S. O. 147, Department of Missouri.* September 25, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING OCTOBER 3, 1885.

JONES, WILLIAM H., *Surgeon.*—To Navy Yard, League Island, Philadelphia, October 15, as the relief of Medical Inspector Michael Bradley.

BRADLEY, MICHAEL, *Medical Inspector.*—Detached from Navy Yard, League Island, Philadelphia, October 15, and placed on waiting orders.

OWENS, THOMAS, *Assistant Surgeon.*—To Naval Station, New London, Connecticut, as the Relief of Surgeon William A. Corwin.

CORWIN, WILLIAM A., *Surgeon.*—Detached from Naval Station, New London, Connecticut, and ordered to the U. S. Steamer "Adams," October 31.

MAGRUDER, A. F., *Surgeon.*—Ordered to the U. S. Steamer "Yantic" without delay, as the relief of Surgeon H. L. Law.

LAW, H. L., *Surgeon.*—Detached from the U. S. Steamer "Yantic," and wait orders.

SIMON, W. J., *Surgeon.*—Detached from the Naval Academy, October 1, and wait orders.

DRENNAN, M. C., *Surgeon.*—Detached from the Naval Academy, October 1, and wait orders.

CABELL, ARTHUR G., *Passed Assistant Surgeon.*—To the U. S. Steamer "Adams," October 31.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING OCTOBER 3, 1885.

BAILHACHE, P. H., *Surgeon.*—Detailed as Chairman of Board for the Physical Examination of Officers of the Revenue Marine Service, September 28, 1885.

VANSANT, John, *Surgeon.*—Order to New Orleans, Louisiana, revoked; to proceed to St. Louis, Missouri, October 2, 1885.

PURVIANCE, GEORGE, *Surgeon.*—To proceed to Louisville, Kentucky, as Inspector, October 1, 1885.

GASSAWAY, J. M., *Surgeon.*—Detailed as Chairman of Board for the Physical Examination of Officers of the Revenue Marine Service, October 3, 1885.

GODFREY, JOHN, *Surgeon.*—Order of September 16 amended; to proceed without delay to Louisville, Kentucky, September 28, 1885.

GOLDSBOROUGH, C. B., *Passed Assistant Surgeon.*—Order of September 16 amended; when relieved to proceed to Chicago, Illinois, October 1, 1885.

IRWIN, FAIRFAX, *Passed Assistant Surgeon.*—Detailed as Recorder of Board for the Physical Examination of Officers of the Revenue Marine Service, September 28, 1885. To examine physically and instruct crews of the Life Saving Service, Third District, in the method of restoring the apparently drowned, October 3, 1885.

ORIGINAL ARTICLES.

RELATION OF HERPES GESTATIONIS AND CERTAIN OTHER FORMS OF DISEASE TO DERMATITIS HERPETIFORMIS.[1]

BY LOUIS A. DUHRING, M.D.,

PROFESSOR OF SKIN DISEASES IN THE UNIVERSITY OF PENNSYLVANIA.

IN my original communication on Dermatitis Herpetiformis, read before the American Medical Association,[2] that disease was described, and its symptoms and several varieties given. It was there stated that the pustular variety is the same manifestation as the affection described by Hebra as "impetigo herpetiformis." This latter subject has more recently been elaborated by me in a paper read before this Association[3] at its last meeting.

On the same occasion I presented a "Preliminary Note on the Relation of Dermatitis Herpetiformis to Herpes Gestationis and Other Similar Forms of Disease,"[4] which communication embodied the results of considerable research into literature bearing upon the subject. It was there stated, as had been intimated in my previous articles, that so-called herpes gestationis, as well as certain other similar forms of eruption, reported with various titles, are all instances of one process, namely, dermatitis herpetiformis, as I had defined this disease.

The remarks about to be made must be regarded as supplementary to the preliminary note referred to, since presenting which I have been able to investigate further and collate the notes of some of these cases, which I desire now to bring forward in substantiation of my statement. It will be observed that the clinical features of the cases bear a strong resemblance to one another. It will not be necessary, however, for my purpose to quote all the cases *in extenso*.

The object of this communication will be to show:

1. The identity of so-called herpes gestationis with the vesicular variety of dermatitis herpetiformis.

2. That certain other forms of so-called herpes reported with various titles are likewise manifestations of the same variety of this disease.

3. That certain cases reported as "peculiar forms of pemphigus" must also be viewed as examples of the vesicular or bullous varieties of this disease.

4. That instances of dermatitis herpetiformis are also to be found in literature under the title "hydroa" and under divers other captions.

In view of the fact that the general features of dermatitis herpetiformis have been so fully described by me, and, moreover, that numerous examples of the disease portraying the more important varieties of the process have been reported during the past year,[1] it will not be necessary to reconsider the disease on the present occasion beyond pointing out the principal features of the two varieties which concern this paper, namely, the vesicular and bullous. The following is an abstract of the original description of the vesicular variety.

It is characterized by variously sized, varying from a pin-head to a pea, flat or raised, irregularly shaped or stellate, glistening, pale-yellowish or pearly, usually firm or tensely distended vesicles, as a rule, unaccompanied by areolæ. In their early stages they can be seen only with difficulty, and are liable to be overlooked in the examination. Sometimes they can only be detected or seen to advantage in an oblique light In size they vary extremely, large and small being formed side by side, and in this respect they differ from the vesicles of eczema. Here and there papules, papulo-vesicles, vesico-pustules, and small blebs will sometimes be encountered. The eruption as a whole is disseminate, the lesions existing scattered more or less profusely over a given region, as, for example, the neck or the back, but they are for the most part aggregated in the form of small clusters or groups of two, three or more; or there may be patches here and there as large as a silver dollar, upon which a number will be seated. When in close proximity they incline to coalesce, as in herpes zoster, forming multilocular vesicles or small blebs. Where this occurs they are generally slightly raised and are surrounded with a pale or reddish areola, which shows forth the irregular, angular or stellate outline of the lesion. At this stage, moreover, the little cluster will generally present a "puckered" or "drawn up" appearance, indicative of its herpetic nature. The eruption is usually profuse, sometimes to the extent of the upper extremities, trunk and thighs being well covered. It may attack any region, but the neck, chest, back, abdomen, upper extremities and thighs are especially liable to invasion.

The most striking symptom is the itching. Not infrequently burning is also complained of. Itching, however, predominates, and is violent or intense. It is altogether disproportionately in excess of the amount of eruption. It is, moreover, a persistent itching, causing the sufferer to scratch constantly. It generally precedes the outbreak, and does not abate until the lesions have been ruptured. From my observation I should say that it is usually more severe and more lasting than

in vesicular eczema. The vesicles generally make their appearance slowly, so that several days or a week may be required for their complete development. Notwithstanding the fact that scratching is indulged in in the early stages of the disease, excoriations are not prominent, owing to the fact that the lesions do not readily rupture, and, also, that they incline to refill immediately on being evacuated.

If we look into the subject of herpes gestationis, it will be found that the term was introduced by Milton in 1872. Previous to this date, in 1867, Erasmus Wilson[1] gave brief notes of two examples of a disease which he designated "herpes circinatus bullosus," considering them in a chapter devoted to the "chronic forms of herpes." In both cases the disease was associated with pregnancy, beginning with conception and ending with the completion of parturition. Mr. Wilson describes them as follows: "Both cases were remarkable for perpetual irritation and intense pruritic suffering. The bullæ were of the flat and foliaceous kind, some filled with limpid serum and others with a mucopurulent fluid, and were associated with moist excoriations, thin crusts, papulæ, and pruritus. In one patient the cutaneous disease was the first intimation of pregnancy; the disease continued during the whole period, accompanied four or five pregnancies in succession, and completely exhausted her strength and health. In other respects, and in the intervals of being pregnant, she was a strong and healthy woman. The other patient was a woman aged thirty-six, the mother of nine children. The eruption made its appearance with the fourth pregnancy, and has accompanied every pregnancy since. When parturition was over the eruption ceased; but on the last occasion, nine months ago, it remained, and has now assumed a permanent character. In both cases the eruption was accompanied with sympathetic gastric disturbance and with a duskiness and cachexia of the skin."

It is evident that the cases illustrate the "herpes gestationis" of certain more recent writers, and, as I have stated elsewhere, that the disease is the same as described later by Hebra under the titles "herpes impetiginiformis" and "impetigo herpetiformis." It must be remarked, however, that Wilson gives no special account of the lesions, nor of the peculiarities of the disease, and it is doubtless for this reason that the attention of dermatologists was not fairly directed to the subject until Milton's report of a case in the *Journal of Cutaneous Medicine*, Vol. i., No. 3, the paper being designated "on certain unusual forms of vesicular eruption," and the disease classed as an example of the "herpes circinatus bullosus" of Wilson. In Milton's work on the "pathology and treatment of skin diseases,"[2] published a few years later, this case is again brought forward, on this occasion with the name "herpes gestationis."

The disease occurred in a woman aged forty-five, who was in the fourth month of her eighth pregnancy. It began with intense itching, smarting, and heat of the skin of the arms and forearms, upon which parts a vesicular and bullous eruption soon developed. The lesions were the size of a small pea, and generally in groups of two to four. They were mostly prominent and pointed in shape, but some were oblong with the ends apparently communicating. The disease developed rapidly, so that in a few days the greater part of the body was involved. There was constitutional disturbance, and the local irritation was most distressing. Two weeks after delivery she was on the road to recovery. She had had similar attacks twice previously, with her first and fifth pregnancies.

We next meet with Bulkley's case,[1] which he, likewise, designated "herpes gestationis," adopting the name proposed by Milton. The case was that of a married woman, thirty-two years of age, who was confined with her first child. The cutaneous manifestations appeared two months previous to her delivery, on the hands and feet, and subsequently involving the greater part of the general surface. It began in the form of papules, which rapidly passed into vesicles, and later blebs developed. The vesicles, which were generally in groups, varied in size from very minute elevations to large blebs. After they had ruptured a brownish stain remained There was at no time any resemblance to vesicular eczema, nor did the lesions pass into pustules. The eruption was attended with intense itching, and later with much prostration and considerable fever.

The disease disappeared after delivery, but recurred with her second pregnancy.

If we look into the four cases just quoted, it will be seen that they resemble one another closely in their clinical features, and that the cause (pregnancy) in all was the same, from which fact both Milton and Bulkley concluded that the term herpes gestationis was expressive and appropriate. This name, as is well known, has since been employed by other observers reporting like cases, and would not be criticised were it not for the fact that the affection is also encountered in men,—an observation which my articles and several of my published cases show; also that it may occur associated with other primary lesions than vesicles, thus rendering the name herpes inappropriate and misleading. The name proposed by Mr. Wilson is even more descriptive than herpes gestationis, and has the advantage of being noncommittal as to the etiology of the process. But the term is not sufficiently comprehensive to include other known manifestations of the same extensive pathological process which cannot be regarded either as varieties of herpes (as this term is understood by dermatologists) nor as having either circinate characteristics or blebs. Thus, we note that while the titles proposed by these observers answered the purpose provisionally, recent studies have demonstrated that this form of disease is but one variety of an extended multiform cutaneous process.

Several other cases, some of them possessing peculiarities, may be cited.

Beverhout Thompson gives brief notes of a case[2] of "herpes gestationis," following Milton and Bulkley, which must be looked upon as the mildest expression of the disease. The patient was a woman, aged

twenty, in the eighth month of pregnancy, the eruption consisting of grouped vesicles and blebs, which were confined to the fingers, toes, backs of hand and wrists, feet and ankles. The attack was an acute one, recovery taking place after delivery, which occurred three weeks after the beginning of the cutaneous manifestations.

With the title "clinical remarks on a case of herpes gestationis," Liveing[1] reports a case that had been under his observation in Middlesex Hospital occuring in a woman thirty-seven years of age. The principal features may be briefly cited. The third day after delivery "a copious eruption of scattered solid papules and discrete vesicles appeared; the latter quickly developed into blebs of various sizes. . . . . The bullæ had a tendency to form groups, but were all discrete, the skin in the neighborhood being more or less covered with scattered solid papules as large as good-sized shot. The itching was intense." Here there was present a marked papular element, the disease being characterized by papules, vesicles, and blebs, and the use of the term herpes, it must be noted, is altogether inappropriate and fails to convey an idea of the clinical picture.

Cottle[2] presents an article on "herpes gestationis," in which a case is given, which illustrates more particularly the multiform variety of dermatitis herpetiformis. The patient was a woman, thirty-eight years of age, the cutaneous manifestation in the first attack, in the first pregnancy, being urticarial in form—in "bumps," to quote the author. In the second attack it was of the same character, but in the third it occurred in the form of relapsing blebs and vesicles. In the same paper mention is made of another similar case, where the lesions were hard papules which later developed into small blisters.

Gale's[3] two cases ("herpes gestationis") may also be referred to briefly. The first was that of a woman, aged thirty-nine, who had suffered on six occasions, usually four days previous to her confinement. It is stated that the disease began like "erythema papulosum," later blebs appearing, and that there was no pigmentation or grouping of the lesions. The second case occurred in a woman thirty-four years of age, the disease having appeared no less than eight times in a period of eleven years, accompanying her pregnancies.

Walter G. Smith[4] with the heading "herpes (hydroa) gestationis," gives the notes of a remarkable case, showing the multiform variety of dermatitis herpetiformis. The patient, aged thirty-five, had been married thirteen years, during which time she had experienced two miscarriages and seven full-term pregnancies. Five years before while pregnant with her third child, in about the sixth month, an eruption, similar to that for which she sought advice, appeared like "ringworm" around the umbilicus, spreading rapidly over the body and limbs. It persisted during gestation and for two months subsequently, and was accompanied by intense irritation, itching, and burning. She remained perfectly free from any cutaneous disease until three months pregnant with the seventh child, the eruption appearing around the umbilicus in exactly the same way as in the first attack, namely, as a cluster of papules or vesicles. Within the first week after parturition the eruption underwent a great aggravation. "Large vesicles and blebs formed, and when punctured clear fluid spurted out with force." When the child was three months old the affection had nearly disappeared, but subsequently a relapse occurred.

The following is an abstract of Dr. Smith's description of the disease at the date of observation. Numerous irregular clusters and groups of papulo-vesicles, and pigmentary stains of the vesicles on the arms; clusters of pimples on the thighs and knees, disseminate lesions down the legs, and blebs on the soles of the feet. Later, there were still to be found a few papules and imperfect vesicles, which looked and felt like the first stage of a variolous eruption." . . . . After each delivery that was preceded by the eruption the nails fell off the hands and feet. At present all the nails are marked with transverse furrows. The eruption came out in successive crops, and each outburst was preceded by a feeling of itching and heat.

The case brings to mind that reported by Bærensprung with the name "herpes circinatus," and depicted in his *Atlas of Skin Diseases*. Hebra regarded this case as illustrating his "impetigo herpetiformis," an observation to which I have elsewhere directed attention.

French writers, with some exceptions, do not seem to have recognized herpes gestationis. M. Barthélemy, however, in his translation of my *Treatise on Diseases of the Skin*, in a note states that "it is the same disease as that which Hebra calls impetigo herpetiformis of pregnant women." Among the recent German authors, Kaposi makes no allusion to herpes gestationis. Behrend only incidentally refers to it (quoting Bulkley) in considering the etiology of pemphigus. Nor do we find more than the briefest reference to the subject in a recent volume on skin diseases by Malcolm Morris. He says "herpes gestationis occurs in pregnant or parturient women, but is rarely seen in England." No mention whatever is made of impetigo herpetiformis (Hebra). In this country the latest author, Robinson, makes herpes gestationis a variety of herpes, placing it between the varieties "progenitalis" and "zoster," and stating that it may be regarded as belonging to the herpetic or pemphigus group of cutaneous diseases, and that he has observed two cases. A separate chapter is devoted to impetigo herpetiformis (Hebra).

Other forms of so-called herpes, such as "herpes pemphigoïde," "herpes vegetans," "herpes pyæmicus," and "herpes phlyctænodes" may here be referred to. The first of these, described by Devergie, will be considered later in connection with pemphigoid eruptions. Herpes vegetans was employed by Auspitz[1] to designate a case subsequently reported and called by Hebra impetigo herpeti-

formis, the case being one of the group of Hebra's cases. Neumann, in his *Hand-book of Skin Diseases*, 3d edition, briefly alludes to the same disease, but regards the term herpes pyæmicus as more expressive of the condition.

Gibert[1] describes a case representing an unusual form of disease under the name "herpes phlyctænodes," as follows: The patient was a woman twenty-seven years of age, who was in 1814 for the first time attacked with a "phlyctenoid eruption," the origin of which she attributed to a severe fright, which she experienced on the invasion of France by the allied troops. Ever since, she has been subject to an anamolous eruption of small vesicular elevations, appearing sometimes on the trunk, sometimes on the face, sometimes on the limbs, and by a bright redness of the skin, and intense itching and smarting. Three years later she had more frequent and violent returns of the cutaneous disease; the catamenial periods became painful, and the discharge scanty. Two years afterwards she entered the hospital St. Louis. The dorsal aspect of the hands and forearms was red, swollen, hot, inflamed, and extremely painful to the touch, covered with a number of small vesicles, most of them miliary, others the size of a pin's head, others even that of a small pea. These elevations, first noticed in the form of small red points, became more sensitive as they enlarged. At first they were colorless and transparent, afterwards turbid and opaque, resting on an inflamed base, most of them distinct, some blended and grouped together, discharging a considerable quantity of fluid on bursting. Violent itching, burning heat, and severe smarting accompanied the eruption, producing restlessness, and causing intense suffering to the patient."

The case without doubt, it seems to me, was an example of the vesicular and bullous varieties of dermatitis herpetiformis, and calls to mind, in its similarity as concerns the etiology, the case of Captain K., reported by me with the title "A Case of Dermatitis Herpetiformis Caused by Nervous Shock."

I come now to the consideration of a series of cases which have been grouped by the reporters under the head of "pemphigus," usually with various adjectival qualifications, which are clearly examples not of true pemphigus, but of that multiform and protean process under discussion. That these cases were not regarded as ordinary pemphigus is manifest from the statement of the reporters that they possessed peculiar characters. The titles indicate that the writers (for the most part well-known dermatologists) were at a loss to classify them, such names as "pemphigus herpetiforme," "pemphigus pruriginosus," "pemphigus composé," "pemphigus aigu pruriginosus" and "pemphigus circinatus," showing a varied and uncertain nomenclature.

I shall cite some of these cases, before doing which, however, a brief description of the bullous variety of dermatitis herpetiformis may be presented, the account being an abstract from my original communication.

It is characterized by more or less typical blebs, tense or flaccid, rounded or flat, usually the former, filled with a clear or cloudy fluid, seated upon a non-inflammatory or inflamed base, varying in size from a pea to a walnut, and mostly irregular or angular in outline. They incline to group in clusters of two or three, the skin between them being reddish and more or less puckered. Sometimes in immediate proximity will exist one, two or three or a part of a circle of small, pin-head sized, flat, whitish pustules. Vesicles, small or large, flat or raised, are also generally found near by or disseminated over the affected surface. As in the other varieties of the disease any region may be attacked, but more especially the trunk, upper extremities, and thighs. The lesions are generally soon ruptured, crusting with yellowish, brownish or greenish crusts. They are accompanied by burning or itching, which may prove severe. They must be distinguished from the lesions of pemphigus, with which of course they may be readily confounded, but they are herpetic in character. They differ in that they incline to group, and have a more inflammatory, herpetic aspect, the type of which appearance is seen in herpes zoster. Moreover, around and near the bleb will usually be found vesicles and often pustules, the latter frequently in close proximity.

Looking into the earlier French literature we find Rayer[1] speaking of pemphigus "circinatus" as a variety of this disease; and stating, moreover, that he was the first to notice it. He gives a case, to quote his words, of "acute pemphigus, with simultaneous eruption of bullæ on the right forearm; annular erythema; herpes phlyctænodes." The patient was an unmarried woman, twenty-three years of age, with regular menstruation. The disease began with itching and the appearance of small red spots which were succeeded by small blebs closely crowded together, which gradually became large and increased in number. Here and there they ran together. As a rule, they were without areolæ. Some of them were opaque. Crusts were also present. Annular patches of erythema were also observed.

Another case, reported by Rayer, is that of "chronic pemphigus; bullæ arranged in bands; complication with herpes circinatus." I shall not give the notes of this case because of their unusual length, but it may be stated that, in my opinion, the disease was one of dermatitis herpetiformis;—the peculiar erythematous patches, herpetic groups of vesicles, blebs, the excoriations and the crusting, the itching, the severity of the attack, and lastly, the duration of the disease, all pointing to this disease rather than to any other affection.

Still another case is recorded by Rayer, as one of "chronic pemphigus, presenting isolated bullæ, and clusters of an eruption similar to that of herpes phlyctænodes; amenorrhœa; recovery." The woman was forty-two years of age. There were constitutional disturbance, severe itching, and a copious diffuse eruption of groups of variously shaped and sized blebs, which appeared in successive crops.

Chausit[2] describes at length two cases, both occurring in women, with the title "pemphigus aigu pruriginosus," which likewise are to be viewed as examples of dermatitis herpetiformis. One of these cases may

Digitized by Google

be quoted. A woman, aged 23, of robust constitution and good general health, was delivered of her first child six weeks before full term. At the fifth month of gestation itching and an eruption of numerous minute solid papules upon the body and limbs manifested themselves, the itching increasing in severity as pregnancy advanced. On the fifth day after delivery she experienced even greater itching and general burning, together with fever and some delirium. The following day the whole surface was covered with a confluent efflorescence of large elevated red papules, resembling in some respects those of erythema papulosum. The skin presented the same appearance for two days, and on the third there were noted on the arms a few disseminated transparent blebs varying in size from a haricot-bean to a hazel-nut. The blebs increased in number until on the eleventh day the whole surface, including the face, was invaded, the burning and itching by this date having ceased. The papules disappeared, new blebs, starting as such, coming out from day to day until the seventeenth day when they disappeared leaving brownish stains. A month after there was slight itching over the general surface together with a few groups of papules, but no more blebs formed.

The papular manifestation preceding and following the blebs would in itself be sufficient to differentiate the disease from true pemphigus, the affection with which it might be confounded.

In considering pemphigus, Devergie,[1] under the heading, "pemphigus composé," gives a case with the title, "herpès pemphigoïde," as follows: "The patient was a woman, fifty years of age, who had ceased menstruating five years before. The disease began with itching, followed by an inflammatory patch covered with large vesicles, which rapidly passed into blebs. Soon various regions were invaded, until the whole surface was well covered with eruption. Large red patches, more marked on their periphery than at the centre, surrounded by one or two rings of blebs, crusting in the centre, formed from time to time. The itching was especially marked on the periphery of the patches. The patient recovered.

As in Chausit's case quoted, the multiform erythematous patches here were marked features in the manifestation; also the subsequent evolution of the lesions, all suggesting a peculiar process. This might be compared to an exaggerated erythema multiforme, showing the several varieties of the disease, especially the bullous, rather than to pemphigus. Indeed, I may here state that dermatitis herpetiformis in some cases manifests itself with many of the clinical features of erythema multiforme. Its relation to this disease is a question in my mind already ripe for discussion.

Devergie also alludes very briefly to "pemphigus herpetiforme," which, he states, he has frequently seen invade the whole body, the patient succumbing to the disease as in other forms of pemphigus.

Hardy[2] divides pemphigus into acute and chronic; under the latter he makes three varieties; first, le pemphigus bulleux successif; second, le pemphigus foliacé; third, le pemphigus prurigineux. The last variety, which he illustrates with a case, should it seems to me be regarded as an example of the combined vesicular and bullous varieties of dermatitis herpetiformis. The patient was a woman thirty-five years of age, who had already had nine children, and was at the date of observation at the close of the last month of her tenth pregnancy. Since her second pregnancy she had suffered, coming on some weeks after conception, from an itching eruption, involving the whole general surface, characterized by blebs the size of a walnut. At the same time the skin became brown, and the seat of a viscid secretion. The symptoms were augmented up to the time of delivery, after which they subsided insensibly.

Under the title of "pemphigus," Klein[1] gives the notes of a case which some writers (Milton and Bulkley) on herpes gestationis have regarded as an example of that disease, but which, if my views be adopted, must be looked upon as another instance of the combined vesicular and bullous varieties of dermatitis herpetiformis. The case was that of a woman thirty-two years of age, the disease beginning in the seventh month of pregnancy, characterized at first by millet-seed sized vesicles, which subsequently developed into blebs as large as a hen's egg, with contents at first clear but later becoming turbid. At the same time severe pains were present, and the strength of the patient declined. The disease disappeared shortly after delivery.

I have next to observe that, under that vague term "hydroa" some cases are found in literature which, I think, might more properly be regarded as examples of dermatitis herpetiformis. Thus, Bulkley[2] gives the notes of "two cases of hydroa," which were read before the New York Dermatological Society, and which it seems should be regarded as examples of that disease. The first case was a married lady, 40 years of age, "who presented a very anomalous eruption, which was then composed largely of bullæ." Three months previously, while in Europe, the disease had been diagnosed eczema by several dermatologists, and was there treated, but with little success. The description given by Dr. Bulkley, especially as relates to the bullæ; the "moist exuding portions of surface;" the "almost unbearable itching;" the constitutional disturbance; the wide extent of the eruption; and the course of the disease, are peculiar and unusual. The case, I think, should rather be classed as an instance of dermatitis herpetiformis than as one of so-called hydroa, the existence of which latter disease, viewed as a distinct process, I am not willing to admit.

In the second case occurring in a married lady aged 26, the first outbreak consisted of erythematous patches, which burned and smarted, and passed away in a few days. Six weeks later there was an attack of

to take necessary food. Recovery was gradual, discharge from the mastoid ceased in the course of the next three weeks. Hearing in that ear remained very imperfect.

CASE IV.—C. K., farmer, aged 54 years, living about four miles from town, called at my office on June 1, 1876, complaining of pain in his left ear. There was no swelling of the meatus, the tympanum was slightly congested, the fauces were inflamed, and the tonsils enlarged. I prescribed for the inflammation, warning him of the threatened disease of the middle ear, and requested him if not materially relieved, to return on the third. He did not return for a week, when he came in and said he was no better. He was again prescribed for, and warned of the danger he was courting, and asked to return at least on the second day. He did not return until June 17th, when he came again complaining that the treatment had done him no good. He was again prescribed for, and warned that if he continued to act as he had been doing, he would have weeks, if not months of suffering, with probable loss of hearing, and possible danger to life, and that he must be seen at least every other day. I did not see him again until the Fourth of July, when I was called out of bed early in the morning to see him. He stood with his head bent forward, his hand encircling his left ear, his face pale and thin, and his whole appearance expressive of the most intense agony. I directed a strong anodyne to be repeated frequently, and ordered him to return home, and promised to see him early the next day. I then learned that in the intervals between his visits to me he had been treating himself by cupping, bleeding, and large doses of quinine as well as a variety of domestic remedies. There had been slight discharge from the ear, but the meatus was now so firmly closed by swelling of its walls that pus could no longer escape. There was some swelling of the mastoid, and also on the face in front of the ear. Any further depletion was out of the question. Anodyne lotions were applied around the ear, and over all warm poultices. Morphia, chloral, and potassium bromide were given in large doses, to procure sleep, of which he had not had more than a few minutes at a time for over a week. I hoped to obtain some discharge through the meatus, but failing in that, and swelling increasing rapidly both in front and behind the ear, incision of the mastoid became imperative. Commencing on a line with the top of the ear, an incision was carried down to the point of the mastoid process, and over one and one-half inches in depth before reaching the bone; a branch of the posterior auricular artery was divided which, in consequence of the great infiltration of surrounding tissues, and its depth in the wound, I failed to ligate, and considerable blood was lost before the hemorrhage could be arrested by compression of the wound. There was no suppuration present and the periosteum remained uninjured. On the second day the compresses were removed without bleeding, and warm poultices applied for several days without relief. Swelling on the face had rapidly increased until the eye was nearly closed. Perforation of the mastoid seemed to be imperatively demanded.

On the following morning, assisted by one of my students, I removed the dressing, preparatory to operation, and found the wound filled with a clot of blood, the removal of which was followed by a strong jet from the divided artery, and five or six ounces of blood were lost before a ligature could be applied. The patient was so much enfeebled that further interference seemed unwise, and was abandoned for the time being. A few days later, after the patient had rallied a little from the loss of blood, without the use of an anæsthetic, I perforated the mastoid with a small bit similar to those used by Dr. Buck, which I had procured and used successfully for drilling the bone in a case of ununited fracture of the tibia. The drill was applied to the mastoid at the level of the floor of the meatus, and directed slightly upward, forward, and inward. At a depth of about three lines I felt that the instrument had passed the hard shell of bone, and was entering a softer and more friable structure. The bit was laid aside, and with a probe the way was readily opened into the antrum. A slight discharge of pus followed through the opening. Swelling of the face continued to increase, and I was compelled to make incisions both above and below the zygoma. Notwithstanding this, the abscess afterward opened and discharged freely within the outer angle of the eye. The abscess healed in a few weeks. All pain ceased in a few days after opening the mastoid. Syringing of the cavity of the tympanum was not resorted to in any one of these cases. A few days ago I saw this patient. and he informed me that he now hears better with that ear than he does with the right ear, which has never been diseased.

The second and third patients are living, and to be seen almost every day, although I have not lately inquired into their condition of hearing.

The first of these cases, related from memory, occurred in the fall, or late in the summer, of 1850, within three years after I commenced the practice of medicine. Aural surgery was then comparatively in its infancy, and had made but little progress toward its present advanced position. I had only read the works of Itard and Kramer on the ear, neither of whom mentions or seems to have thought of opening the mastoid cells as a means of relief from the danger of suppuration of the middle ear. Kramer, in treating of "internal inflammation of the ear," says:

> A sure guide is not unfrequently met with in the simultaneous affection of the mastoid process. . . . On being laid open, either naturally or artificially, the bone is found to be carious; by carefully giving the probe a proper direction, it may thus be introduced into the cavity of the tympanum."

Again he says:

> "Laying open the mastoid process is of much more importance. Whenever fluctuation is discovered, or even when the periosteum yields to the pressure of the finger, the *integuments* should then be divided, and, if necessary, the *periosteum also*."

Thus clearly showing that he never contemplated any artificial opening into the mastoid cells, other than the mere passage of a probe through broken-down, carious bone. Although I knew of the operations of Petit and Jasser and of the death of Baron

Digitized by Google

von Burger, which operations had been done for the relief of deafness, I had never heard of its being done for the relief of suppuration of the middle ear. Guided by the teaching of Kramer, I expected to find an easy passage to the middle ear through carious bone, but, defeated in that, I was illy prepared to encounter so formidable a case. Left to my own resources, I had to act in the emergency without precedent or authority, and without time for consultation or study. Had my case been less hopeless, I would probably have hesitated long before resorting to so hazardous an expedient. Although the anatomical relations of the mastoid region were still fresh in my memory, I had a wholesome fear of injuring the lateral sinus, and selected a point somewhat lower than is now considered best for reaching the antrum.

When I encountered my second case I had read the works of Wilde and Toynbee, was acquainted with the operations of Von Troeltsch, and had no hesitation as to the propriety or necessity of the operation. The only question was, what instrument can be used, as I had none for that purpose. Accustomed to work occasionally in the shop of a gunsmith on the opposite side of the street from my office, who often made and repaired surgical apparatus for me, I remembered a drill which I had frequently used, and which seemed to furnish just the instrument required. One of the bits was selected and fixed in an ordinary handle; it answered the purpose admirably, and I have never used a better instrument.

In the third case a small gouge was borrowed from a cabinetmaker, and used as successfully as the others. The drill would, perhaps, have been better adapted to this case, as the gouge would have been to the former.

The drill and bits of A. H. Buck, now generally recommended, are convenient and well adapted to opening the mastoid cells; but I can conceive of no instrument that equals in any respect the burrs of the surgical engine.

A CASE OF EXCISION OF EPITHELIAL CANCER OF THE RECTUM.

By M. F. MERCHANT, M.D.,
of Genoa, N. Y.

G. A. W., æt. 67, farmer. Health generally good until beginning of present difficulty, which first attracted his attention about January, 1884, consisting of soreness and irritability of rectum, followed in a few weeks by a sero-purulent discharge, often containing considerable blood. Pain increased, becoming more severe at night, and extending down the limbs.

Examination proved the rectum to be the seat of an extensive, hard, and nodular deposit, containing both mucous and tegumentary structure, and extending three and one-half inches up the gut and firmly embedded in its coats. The upper part of the cancerous growth nearly encircled the bowel, while below the deposit was more lateral and posterior. At the margin of the anus, the walls of the rectum had sloughed through posteriorly, destroying the external sphincter muscle.

As the growth could be entirely reached by the index finger, and there appeared to be no undermining of the constitution, with no perceptible enlargement of the glands of the system, the removal of tumor was advised, and, after full consideration, he consented to the operation.

On the 1st of February, 1885, the bowels having been previously emptied, the patient was brought well under the influence of ether, and placed in the lithotomy position.

Assisted by Drs. Frederick Hyde and M. B. Van Buskirk, the operation was performed by carrying an incision entirely around the anus, keeping well outside of all diseased tissue, to the superficial fascia. The gut and tumor were separated from the surrounding healthy structures as much as possible with the finger and handle of the scalpel, using the knife where necessary to separate too firm adhesions. After the removal of all diseased tissues, the gut was drawn down and divided with the knife, removing three and a half inches of the bowel. The divided end was attached to the integument by silk sutures, except posteriorly, where too much tissue had been removed.

The flow of blood was not great. A simple water dressing was applied, held in place by a T bandage, one-fourth grain of morphine given, and patient placed in bed.

Bowels were kept confined for six days, and after second day wound was dressed with carbolized oil and lint.

Slight tympanites occurred on the second day, but soon subsided. Surgical fever was mild, with healthy discharge.

In four weeks patient began to sit up, and in three months was able to be about and perform light work. He experiences no difficulty in retaining feces, except when bowels are lax, and up to time of present writing has continued to improve, and there is no indication of a return of the disease.

MEDICAL PROGRESS.

Laparotomy for Echinococcus of the Spleen.—Dr. Antonio Fibbi, on September 2d, performed the operation of laparotomy for the removal of an enormous suppurating echinococcus cyst of the spleen. The seventh day after operation the patient was in a favorable condition, and recovery seemed probable. At no time after the removal of the tumor did the temperature rise above the normal.—*Gazzetta Medica de Torino*, September 15, 1885.

Purulent Endometritis during Pregnancy.—Dr. Douat records a case of purulent endometritis occurring during pregnancy. This disease subsequent to confinement is an ordinary occurrence, but until the present time no case has been published of its existence during pregnancy. The present observation is therefore unique.

A woman aged twenty-seven years, in whom menstruation had occurred since the age of fourteen, and

Digitized by Google

whose history showed no syphilitic infection or other constitutional disease, entered the clinic at Leipsic, where pregnancy at term was diagnosticated. Labor was rapid and easy.

The amniotic fluid was of a dark green and yellow color, and contained numerous pus corpuscles.

Examination of the placenta and its membranes showed the presence of adhesions and an unnatural condition of the amnion and chorion, between which pus was found. Upon the borders of the placenta the true decidua was infiltrated with traces of thickened pus, and the decidua reflexa was likewise infiltrated with pus. There was no trace of the gonococcus, and it was evident that the purulent process had begun both in the uterine and ovular decidua.

The purulent cells were found scattered between the membranes and had given rise to small abscesses.

As to the cause of the condition, it may in part be attributed to blenorrhagic infection and partly to attempt to produce abortion.

The patient for a long time had been affected with leucorrhœa and presented other physical signs of endometritis.

The chief interest in the case is however, the fact, that purulent endometritis could exist during pregnancy without interrupting its course.—*Archiv für Gynäkologie*, xxix. 3, 1883.

THE BREASTS OF MALE CONSUMPTIVES.—According to M. LEUDET, there sometimes exists a congestive swelling of the breast of male consumptives that is related to the pulmonary disease. There is no deposit of tubercle. The author has observed three cases of this mammary enlargement. The breast is first swollen throughout, and has the characters of a disk whose diameter is about three to five centimetres. The skin that covers the gland does not exhibit any change in color, and the subjacent connective tissue is unaffected. After one gland has enlarged the opposite organ may be affected. Pain is experienced in the diseased gland, and may radiate round the thoracic wall. This swelling is especially liable to occur on the side the lung of which is most diseased, or when pleuritic attacks are notably present. The swelling is regarded as due to a congestion, the result of irradiation from the central disease. The lymphatic glands are not swollen. After lasting from one to several months, the swollen mamma returns slowly to its normal size; suppuration has not been known to occur.—*The Lancet*, Sept. 19, 1885.

THE CAUSES OF RAPID DEATH FROM INTERNAL COMBUSTION.—DR. ALBERTO SEVERI, in an elaborate paper upon internal combustion, and from what reasons it may become rapidly fatal, arrives at the following conclusions.

The factors by which death is produced are:

1. Depression of the vascular tonicity. In the condition under consideration, there is primarily an exaggerated excitation of the bulbar centres of the brain, and hence consecutive depression and paralysis of the same centres.

2. Superheating of the blood. Although the temperature may not be sufficiently high to destroy the corpuscles, as is the opinion of Lesser, this result, according to Trojanoff, is obtained by a temperature of 125⅗° F., which serves also, in part, to produce paralysis of the circulatory centre.

3. The separation and introduction into the circulation of flocculi and small clots, which are found in the heated zone, by the action of the heart and by changes in the vessel walls. Such clots, in the right heart and pulmonary vessels may become nuclei of extensive coagula, and on the other hand they may directly form emboli in the ramifications of the pulmonary vessels. The phenomena which are present during the life of the animal in the first twenty-four hours, and the necroscopic appearances are perfectly in accord with its interpretation.—*Lo Sperimentale*, August, 1885.

THE PATHOGENY OF CERTAIN PARALYTIC SEIZURES OBSERVED IN THE AGED; THEIR PROBABLE RELATION WITH URÆMIA.—DR. RAYMOND, in a series of studies made in the laboratory of M. Velpeau, on the pathogeny of some forms of paralysis observed in old men, and their probable relation with uræmia, holds that in old men

1. Differential diagnosis should be made between cerebral softening or hemorrhage, and certain apoplectic and paralytic phenomena, seemingly connected indirectly with uræmia, or at least appearing to be caused by it under the influence of cerebral œdema.

2. This differential diagnosis is generally very difficult; however, the resistance of premonitory symptoms —such as vertigo, gastric derangement, the demonstration of pulmonary and local œdema, and the presence of albumen in the urine—should lead to the suspicion of uræmia.

3. These paralytic attacks are sometimes due to an old lesion, but frequently they occur without apparent cause.

4. The œdematous condition of the cerebral tissue and ventricular dropsy are the factors which unite to produce paralysis of this nature, either by exciting an old lesion, or by producing differences in the condition of the cerebral hemispheres, not however recognizable by post-mortem examination.

Dr. Raymond further concludes from observed clinical facts and his experiments in proof of the preceding, that

1. In the aged mortal, apoplectic attacks, or at least attacks which are followed by mild hemiplegia, and which simulate the character of hemiplegia, result from cerebral softening, or hemorrhage may occur.

2. Such attacks are due to a condition of uræmia.

3. Autopsy shows, sometimes the existence of an old lesion, and at others simply a generalized œdema of the brain.

4. The pathogeny of these attacks seems in every case to be related with cerebral œdema, and to disorders of circulation resulting from it. These disorders, whether they be congestive or anæmic in their nature, lead to want of oxygen in the cerebral blood supply.

5. It is therefore important as concerning diagnosis, prognosis, and treatment, to give due significance to such clinical and pathological facts, in order to avoid serious errors in appreciating the symptomatology.

6. Cases of sudden death in the aged may be explained by the condition under consideration, a fact of importance in legal medecine.

7. Coincidence in the same patient, of old hemiplegia

Digitized by Google

and chronic nephritis with uræmic tendency, may be the point of departure for convulsive seizures, limited chiefly to the paralyzed side. Disregard of the cases previously studied will lead to clinical errors.

8. Many authors have recorded cases of hemiplegia, absolutely inexplicable by appearances recognized at autopsy. Is it not probable that such belong to the class to which attention is here called?—*Revue de Médecine*, September, 1885.

Physiological Action of Theine.—Dr. Thomas J. Mays, as a result of his experiments upon frogs, concerning the physiological action of theine, concludes:

1. That the anterior part of the body is influenced before the posterior.

2. That it paralyzes sensation before motion.

3. That it impairs sensibility from the centre, and not from the periphery. This is also true of motility.

4. That it produces convulsions which are spinal.

5. That before or during the spasmodic stage there is marked hyperæsthesia.

6. That the general muscular rigidity produced by caffeine when introduced subcutaneously is not present in theine poisoning.

7. That its local action does not produce the characteristic muscular stiffness of caffeine.

8. That it has a more powerful action on the sensory nerve-centres, and less on the motor nerve-centres, than caffeine.—*Therapeutic Gazette*, September 15, 1885.

Physiological Action of Guaranine.—Dr. Thomas J. Mays, from experiments on the frog, to determine the physiological action of guaranine, concludes:

1. That it affects both sensory and motor nerves, the former before the latter.

2. That it paralyzes sensation and motion from the spinal centres, and not, like brucine and cocaine, from the periphery.

3. That it produces hyperæsthesia of the whole body, and after which convulsions.

4. That its convulsions are spinal and not cerebral.

5. That it first increases and then decreases respiration.

6. That it differs in its action from caffeine in that it has a stronger affinity for sensory and less for motor nerves than the latter agent, and that it is more analogous to theine in its physiological action.

7. That it first increases then decreases respiration, and arrests the heart in systole.—*Therapeutic Gazette*, September 15, 1885.

Foreign Bodies in the Conjunctiva.—De Wecker recommends the appended formula for relief of photophobia and orbicular spasm, antecedent to the removal of foreign bodies from the conjunctiva.

℞.—Aquæ dest. . . . . ʒiss.
Cocaine, hydrochlor. . . . gr. iv.
Hydrargyr. chlor. corros. . . gr. $\frac{1}{60}$.—M.
S.—Two drops into the eye.

The preparation is preferable to that containing atropia, on account of absence of mydriatic effect upon the pupil.—*Revue de Thérapeutique*, September 1, 1885.

A New Test to Discover the Presence of Blood in the Urine.—Dr. Antonio Luchini proposes the following test for the presence of blood in the urine, which possesses the advantage of preserving the natural color of the blood:

Ten c. c. of urine, acidulated with a drop of acetic acid, are agitated while cold with three c. c. of chloroform; when allowed to stand, the chloroform will rise to the top, and will be colored more or less intensely, according to the quantity of blood originally present in the urine.

Dr. Luchini has proved the efficiency of the test with ten c. c. of a mixture containing only three drops of blood in 250 c. c. of distilled water.—*Gazzetta degli Ospitali*, September 9, 1885.

The Regeneration of Osseous Tissue.—Dr. A. Bonome (*Arch. Sci. Med.*, vol. ix. 2) gives the following résumé of his experiments upon the transplantation of osseous tissue.

1. The periosteum early manifests, even within thirty-six hours, energetic regenerative processes, by proliferation of the cells of the osteogenetic layer, even when transplanted between muscles or tissues of different nature, such as the anterior chamber of the eye and the iris; it is not developed in nutrient gelatine.

2. The osseous substance, properly so called, isolated from the medulla and periosteum, produces the formation of osteoid trabeculæ through the medium of osteoblasts of the superficial layer, precisely as occurs in bone deprived of the periosteum.

3. Transplantation of the medulla gives negative results.—*Lo Sperimentale*, August, 1885.

Experimental Researches in Tuberculosis.—E. De Renzi, in the *Rev. Clin. e. Ter.*, No. 7, 1885, with a view to decide certain disputed points concerning the nature of tuberculosis, initiated a series of investigations:

1. Concerning the presence of tubercular virus in the blood.

To determine this point, five experiments were performed, by injecting two or three drops of the blood of phthisical patients into the subcutaneous cellular tissue, and the following conclusions reached:

a. In the blood of a patient ill with primary tubercular meningitis, the tubercular virus was present without doubt.

b. The blood of a scrofulous young girl probably contained the same virus.

c. In the blood of phthisical patients, collected with great care, the virus existed, but in less quantity than was found in the sputa.

d. The blood of the same patient did not always reproduce tuberculosis in animals, and this may be explained by the small number of bacteria present, and the different degrees of resistance in animals.

2. To determine the infectious power of the feces of scrofulous and phthisical patients.

To elucidate this point, three experiments were performed, two by injecting some grammes of diarrhœic feces, and in the third case, of tubercular sputa, into the rectum. The results of these experiments seem to show that the disease is inoculated with difficulty in the lower

Digitized by Google

intestinal tract, and when produced is very slow in its development.

It is probable indeed that the feces are free from tubercular virus, and further experiment is necessary to decide the question.

3. The influence of suckling upon the production of tuberculosis.

After six experiments to determine this point, the author concludes that mothers do not directly communicate this virus to children through the medium of the milk.

4. The influence of pneumothorax upon the course of phthisis in cavities.

Referring to his observation made upon a phthisical patient in whom he was able to confirm sensible improvement after the development of the pneumothorax, and describing similar cases reported by others, and having examined the question experimentally, the author concludes

a. That pneumothorax in cavities is easily cured and produces only transitory dyspnœa immediately after the operation.

b. That in cavities in which an attempt to establish pneumothorax was made, the progress of the phthisis was not sensibly modified, nor on section was any difference found between the lungs, notwithstanding the operation was extensively practised.—*Rivista Internationale de Medicina e Chirurgia*, July–August, 1885.

TWO CASES OF HERPES WITH MOTOR PARALYSIS.—DR. G. WALLER communicates to *The Weekblad* of Amsterdam, notes of two cases of herpes, in which motor nerves were affected. A widow-woman, aged 68, had a painful patch of herpes, covering the whole of the right side of the face, stopping abruptly at the middle line. After some weeks the herpetic spots and the pain disappeared, being, however, replaced by paralysis of the same side of the face, with loss of taste on the right half of the tongue. The other case was that of an old man, who had a herpetic eruption situated on the anterior aspect of the upper arm on the right side; this was accompanied with severe itching and a pricking sensation. Eight days after the appearance of the eruption, he found himself unable to raise or extend the arm. There was no pain or swelling in the muscles or joints, and the electric reactions were normal. The herpes and the paralysis both indicated the circumflex and musculo-cutaneous as being the nerves affected. The treatment was electrical, and brought the case to a successful termination.—*British Medical Journal*, September 19, 1885.

PILOCARPINE IN DATURA-POISONING.—DR. LADISLAS ROTH, of Nagy Bajour, Hungary, was called, at 1 P. M., to a little girl, aged 4, in a druggist's shop. She was quite insensible, with widely dilated and insensitive pupils, the face and body being swollen as if dropsical, and covered with a scarlatiniform rash. She was very restless, throwing herself about in all ways, groaning and gnashing her teeth; the pulse was 146, small and weak; the respirations 40, superficial, the temperature 39.5° Cent. (103.1° Fahr.). No urine or stool had been passed since the commencement of the symptoms. The mother said that other children had told her that the child had eaten two handfuls of sweet ripe stramonium-fruit, and, when she saw her at 11 o'clock, she had seemed ill, and unable to stand on her feet. She had called the Government medical officer, who preseribed a mixture containing two grains and a quarter of tartar emetic. The druggist, however, being of opinion that that would not do any good, took upon himself to give a solution of sulphate of copper instead. In the vomit which the copper had produced a number of berries of datura-stramonium were seen. Dr. Roth, remembering a case of atropine-poisoning he had seen reported by Professor Purjek, which had been cured by pilocarpine given subcutaneously, administered, at 12 o'clock, half a centigramme ($\frac{1}{14}$th grain) of pilocarpine, in five centigrammes of water, by means of a Pravaz's syringe. No salivation or sweating followed, and no improvement was detected; and, at a quarter to three, a centigramme was given. The red rash and the swelling diminished. At three, another centigramme was given. The child cried, and shortly began to show various signs of improvement. The injections were continued. Up to 5 o'clock, $\frac{11}{14}$ of a grain had been given. At six, the pupils had become almost normal, and the pulse 120, and temperature 103.6° F. She was able to speak quite plainly, and wanted something to eat. All this time, there had been no sweating. At 7 o'clock, as her condition appeared somewhat less satisfactory, half a centigramme more was given, and this brought on both salivation and sweating. She made a rapid recovery. Altogether, six-sevenths of a grain of hydrochlorate of pilocarpine were administered, five of which, the writer considers, were required to neutralize the datura.—*British Medical Journal*, September 19, 1885.

ACTION OF NITRO-GLYCERINE ON NEPHRITIS.—R. B. BURZHINSKI, in *Vrach*, gives the result of his experience with nitro-glycerine in the treatment of nephritis as follows:

1. Nitro-glycerine in small doses diminishes the quantity of urinary albumen passed per diem, and still more markedly the percentage of albumen in the urine.

2. The diurnal quantity of urine is perceptibly increased by nitro-glycerine, this increase persisting some time after the nitro-glycerine has ceased to be given.

3. Gradually increasing doses of nitro-glycerine influence still more decidedly the formation of albumen.

4. I have been unable to determine the influence of nitro-glycerine on the weight of the urine, the weight of the patients, and on the dropsy.

5. With the exception of slight and transient headaches, nitro-glycerine does not give rise to any disagreeable symptoms. — *The Practitioner*, September, 1885.

CÆSAREAN SECTION WITH SUTURE OF THE UTERUS WITHOUT MUSCULAR RESECTION. — VON LEOPOLD, at the conclusion of a report of two additional cases of Cæsarean section with suture of the uterus and without muscular resection, lays down the following rules for operation:

1. Preparations for the operation should be as restricted as possible, but the external and internal genitals should be carefully washed with solution of corrosive

Digitized by Google

sublimate, 1 : 2000, or with three per cent. carbolic solution.

2. Operate as early as possible at the end of the first stage of labor.

3. Obtain a reliable assistant, who, previous to the operation, must inform himself concerning the operation in all its details.

4. The uterine incision must at first extend only to the movable peritoneum, but will finally be extended to the fundus.

5. After the delivery of the child and before the removal of the placenta, slip the uterus from the abdominal cavity, and,

6. Induce cessation of hemorrhage by compression of the neck of the uterus by an elastic ligature, regulated by the hand.

7. Undermining and resection should only be performed if the serous edges of themselves do not coaptate on account of muscular contraction, and the surfaces of the wound protrude. Preparation for this operation is necessary; and undermining may first be performed, and followed by resection. Both, probably, are always preferably to be avoided.

8. The uterine incision should first be closed with deep silver sutures, avoiding the decidua. The internal margins of the muscular borders will be best coaptated if, previous to the drawing taut of the sutures, the uterus is compressed laterally, as thereby the outer edges gape but the inner come into apposition. The sutures should now be tightened, and the uterine wound is thus closed under the eye of the operator, from within outward. Too firmly drawing the sutures together must be avoided. Superficial sutures of fine silk give the best results. The serosæ are thereby folded, as usually occurs spontaneously; the superficial suture of each serous border in the middle portion of the wound is always best when double, while at the ends a single transfixion is sufficient.

9. After suture of the uterus, the elastic ligature is removed, and the remaining steps of the operation are concluded according to the methods of laparotomy.—*Archiv für Gynakologie*, Bd. xxvi. Hft. 3.

The Modification of the Biliary Secretion in Febrile Processes.—Dr. G. Pisenti (*Arch. per le Sci. Mediche*, vol. ix: p. 2), in an experimental study to determine the effects of febrile conditions in modifying the biliary secretion, subjected dogs to intravenous injection of septic material and to confinement in an elevated temperature. By the first procedure, *septic fever* was produced and as a result of confinement in high temperature, *a fever from retention of heat.*

In both sets of experiments a rise of temperature was noticed, ranging from 2° to 4° C. The results of his experiments are thus recorded:

1. The biliary secretion always diminishes during the existence of fever, whether resulting from septic condition or from retention of heat, and the diminution noted varies from one-half to one-third of the amount secreted under normal conditions.

2. The quantitative variation of the fluid portion of the bile is demonstrated in both forms of fever, and is in relation with the duration and height of the fever, while changes in the elimination of the solid materials vary according to the nature of the febrile process.

In septic fever, the quantity of the solid materials is diminished in proportion to the decreased velocity of the blood in the portal system. On the contrary, in fever due to the retention of heat, the quantity of solid materials eliminated increases with the rise in temperature in relation with the altered conditions in the portal circulation.

3. In fever, the bile which escapes from fistulæ contains more mucus than normal; in septic fever the quantity is greater than in that due to the retention of heat.

4. In fevers generally the coloring matters of the bile undergo changes and modifications in their chemical constitution, by which the bile becomes black and afterward of a dark green color.

5. The normal condition of the biliary secretion is reëstablished very slowly after septic fever, but with greater rapidity after fever from the retention of heat.

6. The alterations in the biliary secretion during the existence of fever are not due to organic lesions,—as the author has found by microscopic examination of the liver of animals experimented upon,—but are found to be entirely functional.—*Lo Sperimentale*, August, 1885.

The Bruit de Galop.—M. Potain, at the recent meeting of the Congress for the Advancement of Science, advanced a new theory of the bruit de galop, according to which the bruit results from the sudden tension of the ventricular wall subsequent to the entrance of blood into the cardiac ventricles.

In support of his views the annexed facts are brought forward:

1. The bruit is always diastolic.

2. It results from the entrance of the blood, with which it always coincides, and which is always the only active movement produced at this moment.

3. It is not necessarily connected with the auricular systole, and may be produced without relation to it.

4. It appears to occur at the moment when the ventricular wall enters into diastolic tension, and, moreover, it is more accentuated when that wall is more rigid or inextensible, a condition which necessarily increases its intensity.—*Journal de Médecine de Paris*, September 20, 1885.

Hypodermic Injections in Anthrax.—Olavide (*L'Union Médicale*, September 26, 1885) recommends as a hypodermic injection in anthrax:

℞.—Acidi carbolici . . . . fʒj¼.
Alcoholis . . . . fʒijss.
Aquæ dest. . . . . fʒiv.—M.

At the beginning of the disease injection at the base of the tumor should be made with the solution. Pain is diminished, the swelling diminishes, and the fever is diminished and disappears entirely the third day.

By continuing the injections and covering the diseased surface with lint soaked in the same solution, there occurs, according to Olavide, resolution of the anthrax about the eighth day.

Astragaloid Osteotomy in the Treatment of Flatfoot.—Professor William Stokes, in discussing the treatment of flatfoot by astragaloid osteotomy, makes in conclusion the following observations:

1. That the theory of ligamentous relaxation being

Digitized by Google

the chief factor in the production of flatfoot is erroneous, being in the majority of cases the result and not the cause of that deformity.

2. That elongation of the calcaneo-scaphoid ligament should not be mistaken, as it so often is, for relaxation of it.

3. That the altered direction of the sustentaculum tali is a change that could not be directly or indirectly connected with either ligamentous relaxation or muscular paralysis.

4. That the osseous deformation, whether resulting from original malformation, or rickets, or other pathological change in genu valgum—a condition until quite recently believed to depend solely on ligamentous relaxation—furnishes an *à priori* argument in favor of the author's theory.

5. That the treatment of pes planus in cases, at all events, where the deformity is irreducible should be directed mainly to restoring the arch of the foot by operative interference with the misshapen astragalus.

6. That this is feasible without destruction of the medio-tarsal joint.

7. That the evidence in favor of muscular paralysis being an etiological movement in the production of flatfoot is insufficient and unsatisfactory.

8. That deformity of the scaphoid, the result of disease, may also be looked upon as a cause of flatfoot.

9. That the appearances in the specimens noted by Mr. Symington and the author furnish strong proof of the truth of the connection between flatfoot and original osseous malformation.

10. That, after astragaloid osteotomy, it is desirable to keep the foot, during the healing of the wound, in a state of supination, which can be conveniently effected by the application of a Dupuytren's splint, as used in fractured fibula.—*Annals of Surgery*, October, 1885.

THE RESULTS OF COMBINED SPLENECTOMY AND THYROIDECTOMY IN DOGS AND RABBITS.—G. B. UGHETTI and E. DI MATTEI (*Arch. Soc. Med. Bizzozero*, vol. ix. p. 2) find, from experimental removal of both spleen and thyroid body in dogs and rabbits, that

1. Total thyroidectomy causes the death of animals in from 4 to 15 days after the operation, with the same phenomena already observed by others.

2. Splenothyroidectomy done at a single operation produces death in dogs in from 4 to 16 days after the operation, with occurrence of the same symptoms observed after total thyroidectomy alone.

3. By thyroidectomy and consecutive splenectomy, at different times and with an interval of from 5 to 9 days, the dogs succumb as before but suffer much more if chloroformed for the consecutive splenectomy.

4. Dogs in normal condition are not affected by transfusion of blood from dogs upon which thyroidectomy has been practised, whether made through the peritoneum, the veins, or directly from the carotid artery into the jugular vein.

5. Dogs from which the thyroid has been removed when subjected to transfusion, even though from dogs upon which thyroidectomy has been performed, live longer than when transfusion is not practised.

6. Of five dogs in which a single lobe of the thyroid was removed, one died after 4 days, a second after 6 days, and no effect whatever was observed in the remainder.

7. Isolation of the two lobes of the thyroid body, is followed by neither local nor general disturbance.

8. Total thyroidectomy in the rabbit is not followed by any disturbance or death.

9. Rabbits survive splenothyroidectomy done at a single operation.

One female thus operated upon became pregnant and brought forth at term healthy offspring with both organs present.—*Lo Sperimentale*, August, 1885.

SPONTANEOUS RUPTURE OF THE STOMACH.—DR. J. CLARKE reports two cases of spontaneous rupture of the stomach, an occurrence so rare as to render it extremely interesting, especially from a medico-legal standpoint. The two cases recorded were instances of rupture of the stomach, and not a mere perforation of the walls of that viscus. The coats of the stomach in one case were atrophied and thin, but in the other were healthy; and in neither case were the coats of the organ, softened or eaten away in irregular patches by the action of the gastric juice. In both cases the stomach was empty at the time of rupture; and in both the gastric juice acted only on the spleen, digesting off its capsule and peritoneal coat, in patches, and thus allowing the escape of blood into the abdominal cavity. Dr. Clarke thinks there can be no doubt that the rupture in both took place before death, and was not due to post mortem softening; the seat of rupture was on the anterior wall. The mucous membrane and peritoneal covering could be traced up to the margin of the rent, and did not present any marked degree of irregularity; and there was an absence of softening, erosion, or rupture on the posterior wall of the stomach.—*The Indian Medical Gazette*, August, 1885.

THE VACCINE FLUID OF M. FERRÁN.—At a recent meeting of the Académie de Médecine de Paris, M. CHANTEMESSE, in his own and M. ROMMO'S name, made a report upon the vaccine fluid employed by M. Ferrán. Two samples were examined, the first brought from Spain by M. Rommo; the second sent directly by M. Ferrán. The results of their experiments and investigations are embodied in the appended résumé:

1. The vaccine of M. Ferrán is not a fluid the culture of which is invariable; sometimes it is an impure culture of comma-bacilli; at others it is a liquid containing masses of microörganisms, while the comma-bacillus is almost absent.

2. In various cases the subcutaneous absorption of the so-called vaccine did not protect from the stomachic injection of a pure culture of the comma-bacillus, according to the known methods. Its vaccine power in their experiments is shown to be *nil*.

3. Injected beneath the skin of India-pigs, even in the dose of several cubic centimetres, the vaccine caused no appearance of choleraic phenomena. According to its composition and the dose injected it sometimes produced inflammation, and sometimes was without result. Cultivated separately the different microörganisms therein are discovered to possess different morphological features and pathological properties. In considerable dose some of them occasion death.—*Journal de Médecine de Paris*, September 20, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, OCTOBER 17, 1885.

RARE NERVOUS SYMPTOMS IN DIPHTHERIA.

ABSENCE of the patellar tendon-reflex after diphtheria has been recorded by several writers, but the observations of BERNHARDT, which appear in a recent number of Virchow's *Archiv*, would seem to indicate that it is not a frequent sequence of this disease. Of twenty-one cases examined during convalescence it was absent in thirteen on both sides, and in one case on one side only. The abolition of the reflex comes on from three to six weeks after the commencement of the attack and is not reëstablished for five or six months. It usually occurs without any indications of affection of the nervous system, but the symptoms of post-diphtheritic ataxia may be present, though even when this exists the patellar reflex is not necessarily absent.

UHTHOFF reports a case, in a boy of ten years, who began to have disturbance of vision fifteen days after an attack of diphtheria. There was complete paralysis of accommodation with retention of the pupillary reflex. Four or five weeks later complete external ophthalmoplegia with ptosis made its appearance, and paresis of the legs with ataxia and abolition of the patellar reflex followed the ocular symptoms. At the end of sixteen weeks the boy began to improve, and complete recovery took place in about four months later.

MENDEL has published an analogous case with a careful microscopic examination of the nerve centres. A boy, aged eight years, had, in the early days of convalescence from diphtheria, paralysis of the palate. Six weeks later, almost all the eye muscles on both sides were involved, without any impairment of accommodation or diminution in the field of vision. There was paralysis of the muscles of the neck, and of the right facial nerve, incoördination of the muscles of the extremities, and absence of the patellar reflex. The sensibility was normal, with the exception of slight hyperæsthesia of the legs. Death took place from paralysis of the respiratory muscles. The autopsy showed arterial and capillary congestion with minute hemorrhages along the roots of the nerves in the entire region from the corpora quadrigemina to the decussation of the pyramids. The nuclei of origin of the nerves were normal. The nerve cords, particularly the oculo-motor, showed interstitial and parenchymatous neuritis in an advanced grade. The changes in this case point conclusively to a peripheral affection of the nerves, and are in accordance with the well-known views of Charcot and Leyden.

The neuritis may be excited in some instances by the local action of the diphtheritic virus. In the case of the velum palati, so often attacked, the branches of the nerves are directly involved; and Mendel refers to an interesting observation of Küssmaul, in which a diphtheria of the umbilical cord in an infant was followed by paralysis beginning in the abdominal muscles.

Mendel has also seen three cases of post-diphtheritic hemiplegia due, he thinks, to vascular lesions; in all, the paralysis was entirely motor, it involved the face and extremities on the same side, and developed suddenly, without warning, and without loss of consciousness. In one of the cases which terminated fatally, a spot of hemorrhage was found in the region of the lenticular nucleus.

REMOVAL OF THE OVARIES ON ACCOUNT OF UTERINE TUMORS.

THE operation which is generally known as Battey's, consists in the removal of the healthy or only slightly diseased ovaries, to produce a premature menopause. Various indications have been given for this operation, and the number of cases in which it has been performed increases almost daily. By this constantly enlarging experience the value of the operation will be determined, and the cases to which it is legitimately applicable will be decided.

Apart from any danger in the operation, it must always be regarded as a very grave act to remove a woman's ovaries while she is still in the reproductive period of life. Notwithstanding the statements of some writers as to the persistence of sexual desire and pleasure in women whose ovaries have been taken away, this is not the chief point; if woman were created simply as the minister of lust, to receive and give sexual pleasure, there would be great strength in the argument. But she was made to be a mother, to bear a most important part in the continuance and in the increase of the race, and if her ovaries are removed, this chief end of her existence is at once

Digitized by Google

and forever gone. Just as the late Dr. Gross stated as to making an artificial vagina when the uterus is absent—an operation which he unqualifiedly condemned—you do not by the operation fit a woman to be a wife, but to be a prostitute. So in ablation of the ovaries a woman is denied a wife's true crown, maternity, and may be degraded to a prostitute's condition. We must think that the argument as to the continuance of her sexual gratification, used by some of the advocates of the operation, is an appeal to the lower elements of human nature, and may be cast aside. Questions relating to this gratification are rarely proper or necessary topics for professional conversation, and we imagine many women would shrink from answering them, if not actually resenting their presentation.

Still further, we believe that an unmarried girl who has had her ovaries removed has no right to enter marriage—her necessary sterility debars her from it, and this she ought to be told before her consent to the operation is given.

But that the ovaries may and ought to be removed for certain diseases cannot be doubted. The interests of the individual become paramount, and those of the race are given no weight; her life must be saved, even at the sacrifice of all possibility of her having offspring. Now it is in the discrimination as to these cases that not only scientific knowledge and professional experience, but also ethical considerations enter: the removal of the normal ovaries is always a question in morals, as well as in medicine, and cannot be evaded in either relation without evil results.

One of the applications of Battey's operation has been considered at some length by Dr. Notta in a recent number of *L'Union Médicale*. It concerns hemorrhagic fibro-myomata of the uterus. Notta goes so far as to suggest that it is probable these growths give the sole indication for the operation. His views are in direct opposition to those expressed by Dr. E. Schwartz, in the recently issued thirty-seventh volume of the *Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques*. The latter states:

"Notwithstanding some successes from this intervention, we think it should not be resorted to unless ablation of the uterus is absolutely impracticable and medical treatment insufficient, for when one makes a patient run the risk of laparotomy, it is necessary at least to give her decided chances of cure; now hysterectomy appears in this connection the sole rational operation, and if in some cases Hegar's operation has acted favorably, more frequently still it has not attained its end."

Of course removal of the ovaries, or of the uterus, ought not to be done until medical means have been ineffectually tried, but certainly the latter operation carries greater risk to life than does the former, whether called by the name of Battey, or of Hegar, and therefore should be rejected if anything like as good results can be secured by the other.

Notta gives the following conditions as indicating removal of the ovaries: The uterine tumor of mean, especially of small size, and directly inaccessible; causing incoercible metrorrhagia, which places the patient's life in danger, she being still young, and medical means for the cure of the hemorrhage having failed.

He quotes from a recent thesis of Tissier which includes 171 cases of castration in women suffering from uterine fibro-myomata, to the effect that there were 25 deaths, or a mortality of 14.16 per cent. In 135 of the remaining 146 the desired end was attained; that is, the uterine hemorrhage ceased, and the menopause occurred.

These statistics probably present the operation in its most favorable light, but even those of Wiedow do not justify resort to it unless other methods of treatment have failed. It sometimes happens that a tumor which has caused grave hemorrhages, becomes pedunculated in the uterine cavity, and its removal through the vagina can be done with little risk, and the integrity of the woman's sexual organs is kept. Patient waiting, palliation, and temporizing are required; the result is more slowly attained, a brilliant successful laparotomy is not proclaimed in societies and journals, but the ultimate condition of the patient is every way preferable, for she has undergone no mutilation, and the possibility of maternity remains to her. On the other hand, the tumor may become pedunculated in the peritoneal cavity, the hemorrhage ceasing with this change in position of the growth.

We are persuaded that in some cases of uterine fibroids causing metrorrhagia, a masterly inactivity, so far as surgical means are concerned, or simply an armed expectation, is the wiser plan. If one knows how to arm himself with patience, and to inspire the sufferer with confidence, he may find that the great majority of his cases of uterine fibroids will get on well without surgical treatment. Thorburn regarded 10 per cent. as a most liberal estimate of those cases that require the aid of the operating surgeon.

DURANDE'S REMEDY FOR GALL-STONES.

It is very generally acknowledged that the idea of dissolving calculi within the gall-bladder by the administration of medicine, is a therapeutic delusion; yet it is deeply implanted in the professional mind, and there are probably few practitioners who have not used lithontriptics of one kind or another. Of such remedies the mixture of sulphuric ether (three parts) and turpentine (two parts) as recommended by Durande, in 1774, has long been a favorite one.

Digitized by Google

Certainly it has stood the test of time, and held its ground while systems of therapeutics have had their day and ceased to be, and has made the name of the learned Professor of Dijon to live, while his numerous chemical and botanical researches have long been consigned to oblivion.

Results described as brilliant have been reported by a long series of physicians of all countries, from Haller and Sömmernig, in the last century, to the most recent authors in our systems and dictionaries of medicine. The mode of action is unknown; it is given empirically, but those who have faith in its efficacy hold that a positive solution of the calculi takes place under its use; others think that it is beneficial only in relieving the colic and permitting the stones to pass more easily, and the title of Durande's original paper leads one to infer that this was his view. Stimulated by the cure of a case at Professor Botkin's clinic, by the use of this remedy after a prolonged trial of alkalies, LEWASCHEW (Virchow's *Archiv*, cii, 3) has made a very careful experimental study of the action of the sulphuric ether and turpentine, alone and combined, on the biliary secretion. By means of carefully devised fistulæ, through which the bile could be collected and estimated, the effect of the remedies when introduced into the stomach could be ascertained. The experiments very clearly show that, singly or combined, the ingredients of Durande's mixture powerfully influence the secretion of the liver, increasing it in quantity, and diminishing the consistence. There does not appear to be much difference in the intensity of the action of the separate ingredients, but the turpentine acts more slowly. The combination, tried in various proportions, did not have any greater influence than when the drugs were used singly. The mixture of ether and castor oil, as recommended by Duparcque, did not induce a more active secretion than the ether alone. The effect of the remedy in man may be said to depend, not on any power of solution of the calculi, but on its great cholagogue effect, and the furthering of the passage of the stones through the duct. No doubt, too, by diminishing the consistence of the secretion it may prevent the development of other concretions. The ether was found to have a decidedly more intense action on the secretion than the bicarbonate of sodium; on the other hand, in comparison with the salicylate of sodium, the action of Durande's remedy is slight and transitory, and the author recommends it strongly as the most effective agent in augmenting the quantity and reducing the consistency of the bile. In his former investigations on the action of alkalies on the composition of the bile, he found the effect much intensified by combining them with large quantities of water, and, no doubt, we here have the secret of the success of the cure of cholelithiasis by Vichy and other mineral waters.

MEDICINE IN CHINA.

THE second annual report (1884) of the Soochow Hospital, which is under the control of Methodist Episcopal missionaries, shows a very gratifying state of affairs and real progress in the work of introducing Western medicine into China. Everywhere, throughout the East, the advantage of combining the medical and theological professions is so evident, and the demand for medical missionaries has become so urgent, that many earnest men, to be better equipped for the work, have temporarily given up their proselytizing labors to return to Europe or this country to study medicine.

At several stations hospitals have been established at which the natives can receive treatment, and medical schools at which native pupils can follow a regular course of instruction. The Soochow Medical School, established in 1883, has eleven native students, all, save one, Christians, and the course which is laid down seems very complete, comprising a five years curriculum, with a thorough preliminary examination in Chinese classics, and a nine months' session. The lectures are in the native language, and through the labors of Osgood, Kerr and others, the students have an ample supply of text-books in Chinese.

At the hospital nearly 12,000 patients were under treatment during the year, the great majority, of course, in the dispensary. Some interesting facts may be gleaned from the classified list of diseases treated. More than a third of the cases are under the three divisions of intermittent fever, diseases of the eye, and diseases of the skin. A remarkable feature is the prevalence of quartan ague. Of the cases of intermittent, 1391 in number, 1253 were of this type, and in nearly all the paroxysm occurred in the afternoon part of the day. Another singular fact is that foreigners, living for years in the same locality and exposed to the same source of poison, will almost invariably have the tertian form, while their Chinese servants or neighbors have their chills after an interval of two days. The absence of severe remittent and congestive types of malarial poisoning is somewhat remarkable. There were no cases of the filaria hominis sanguinis, and no instances of the distoma of the bronchial tubes, which has been shown to be a fruitful source of hæmoptysis is the East. Two hundred cases of the opium habit were under treatment, and it is proposed to put up a separate opium refuge so soon as funds are forthcoming.

The financial statement shows how much can be done in practical charity with very little money. The record of attendance at chapel alone reminds us that this is a report from a missionary hospital, and it reminds us too of the labor and toil which these zealous members of the profession gladly undertake for the sake of a higher object. The mental con-

Digitized by Google

dition of sick persons is mobile and favorable to change, a psychological fact which has been taken advantage of by theologians in all ages. When the blood creeps and the nerves prick and tingle, when the bones and flesh are touched, the mind is unstable and easily moved, and the missionaries find that in the process of repairing the "frail earthen vessels," they have the best opportunities for the work to which their lives are devoted. In the modern crusade the stethoscope has replaced the sword.

No notice of the state of medicine in China would be complete without a reference, however brief to the splendid work which the medical officers of the Imperial Customs have been and are doing to advance our knowledge of the diseases of the East. We could wish the *Imperial Customs Medical Reports* a much wider circulation than it seems to have, in this country at least, for scattered through its issues are many important contributions of general interest. Working in an unknown field, they have found many things new and strange, particularly among parasitic diseases. The researches of Patrick Manson on the filaria disease have been of extraordinary interest to biologists and physicians, and within the past few years we have in succession the announcement of the discovery of two new parasitic affections due to the distomes or flukes, helminths which have heretofore played a minor rôle in human pathology. Parasitic hæmoptysis appears endemic in certain regions of China and Japan, and is due to the presence of the distoma Ringeri in the bronchial tubes and lung tissue. In some districts a considerable percentage of the people are affected with severe liver disease, due to the occurrence in the bile passages of another fluke, distoma perniciosum, which produces a disease similar to the "rot" in sheep, caused by the common liver fluke. The last numbers of the *Reports* contain an interesting description of the disease by Dr. Wallace Taylor. A second species of distome has been found in the liver of man in Japan and China, and as it does not appear to produce a severe disease, it has been called D. innocuum. Bælz has lately affirmed that this species is identical with the D. perniciosum, but in the specimens which we had an opportunity of examining there were sufficient differences to indicate that they are distinct species, or, at any rate, well-marked varieties.

In the beginning of the Congress controversy extreme solicitude was expressed by some members of the Association for the assertion of its supreme authority in everything pertaining to the organization of the Washington meeting, and its *Journal* devoted many pages to advocating this point. Now, however, that the new Executive Committee has proclaimed its independence of the parent Committee and of the Association, by formally declaring that its acts are "not subject to revision, amendment, or alteration by either the Committee of Arrangements or the American Medical Association," the *Journal* has not a word to say against their usurpation of power, or about the propriety now of maintaining the authority of the Association in the premises. It does not point out how the *new* Committee have laid themselves open to "the charge of having ignored the body from which its existence and all its powers had been derived," or how *they* "coolly turn the Association into a 'football' and contemptuously kick it out of their way." It no longer talks about members making "a bold attempt to use the National character and prestige of the American Medical Association as a 'decoy duck' to obtain their own appointment to office." The authority of the Association is openly defied by its own Committee, and its *Journal* suddenly becomes silent on the subject.

REVIEWS.

DISEASES OF THE TONGUE. By HENRY T. BUTLIN, F.R.C.S., Assistant Surgeon and Demonstrator of Practical Surgery and Diseases of the Larynx, St. Bartholomew's Hospital; lately Erasmus Wilson Professor of Pathology at the Royal College of Surgeons. Illustrated by chromo-lithographs and engravings. Small 8vo. pp. 445. Philadelphia: Lea Brothers & Co., 1885.

THIS book, the latest issue of the "Clinical Manuals for Practitioners and Students of Medicine," is a model of its kind. Since Fairlie Clarke's work appeared in 1873, no extended treatise upon diseases of the tongue has been published in the English language, and Clarke's book is now in many respects far behind the times. This treatise is, then, specially welcome, all the more so that the text is really *illustrated* by a sufficient number of admirably executed colored plates, and not rendered more confusing by absurdly colored daubs.

The work has been written by one whose opportunities have peculiarly fitted him for the task, since he teaches not only from a clinical but from a pathological standpoint. While we see very much to praise, there are yet a number of points which seem to us open to criticism. Lack of condensation and needless repetition might have been avoided in some sections, and some omissions are regrettable, such as the overlooking of the fact that certain bursæ, when enlarged, may simulate tumors of the tongue. Still these are but minor blemishes, and we heartily commend the book to our readers. We wish that all general practitioners would read at least two portions, viz., that which treats of mucous patches, etc., of the tongue, wherein it is shown that constitutional treatment, without local, is too often of little value; and the following: "If there be one thing more harmful than another in the treatment of simple indolent sores of the tongue in persons over thirty years of age, it is the application of a strong caustic." Either let the disease alone, or remove it with the knife or

Digitized by Google

actual or galvanic cautery. Similar remarks are applicable to the treatment of other tongue affections, notably warty growths.

Two other interesting points and we have done, for it would be impossible to do anything like justice to this little book without a many-paged review. Mr. Butlin maintains that in microscopic examinations of scrapings of carcinomatous ulcers, among non-important substances, many irregularly shaped, multinucleated, malformed, epithelial cells, together with "cell-nests," will be found; while in the examination of scrapings of more than one hundred tongues, either healthy or variously diseased, but not carcinomatous, nothing that could be mistaken for a cell-nest was to be observed. He does not, so it seems to us, unduly magnify the importance of such microscopic examinations, to the exclusion of a careful consideration of all the general characters of the disease, but merely says that in a number of cases he or his colleagues have been by such means enabled to make a definite diagnosis in doubtful cases.

The second and last point which our space will enable us to mention is the peculiar view advanced by Mr. Butlin, that "fur" on the tongue, either in health or disease, is essentially due to the multiplication of microorganisms, chiefly micrococci and bacteria subtilis. His arguments in support of his views could only be stated by means of long quotations or paraphrases, so that we must refer the reader to the original.

The author is occasionally a little slovenly, and consequently obscure, in his style, and indulges in certain inelegancies which mar his work in critical eyes; but we again repeat that the book is a good one, and a real addition to our surgical literature.

SOCIETY PROCEEDINGS.

THE PHILADELPHIA PATHOLOGICAL SOCIETY.

Stated Meeting, September 24, 1885.

THE PRESIDENT, E. O. SHAKESPEARE, M.D., IN THE CHAIR.

DR. WILLIAM OSLER presented specimens of

TÆNIA ECHINOCOCCUS.

This rare parasite was reared experimentally by feeding a dog with hydatids from the liver of a pig. The animal was killed about seven weeks after the feeding, when the small intestine was found to contain many hundreds of the mature tapeworms. The portion of bowel exhibited had many adherent to the mucous membrane. From the small size of the worms, only a few lines in length, they are very apt to be overlooked. Cobbold states that the only specimens procured in England have been experimentally reared. Dr. Leidy has never met the adult worm in this country. That it must occur here in the dog is very evident, from the frequency with which echinococcus cysts (the larvæ) are met with in the hog and other animals.

CYSTICERCUS CELLULOSUS.

DR. OSLER exhibited the heart, brain, and a portion of the flesh of a pig containing the "measles," as the larvæ of the tænia solium are called. Both organs were thickly studded with the cysts, which were also very numerous throughout the muscular system. The animal was fat, and seemed to suffer very little inconvenience. Attention was called to the cysts beneath the tongue, and to the possibility of telling whether an animal was measled by an examination of this part during life. Microscopic slides of the parasites were shown, and a slide of a cysticercus, with a very large caudal vesicle, from the omentum, in which situation they may grow to the size of a walnut.

DISTOMA HEPATICUM; EFFECTS ON THE LIVER.

DR. OSLER also showed the liver of an ox with enormous enlargement of the bile vessels and calcification of their walls, due to the chronic inflammation excited by the presence of the flukes. The main ducts were thicker than the thumb, and even the smaller tubes were as hard as the stem of a clay pipe. The liver substance was wasted, but not cirrhotic. In spite of this extensive disease, the animal was well nourished. Specimens of the flukes in spirit and mounted were also shown.

DR. WILLIAM PEPPER presented before the Society the specimens of

TÆNIA FLAVO-PUNCTATA,

described by Prof. Leidy, in the *American Journal of the Medical Sciences*, for July, 1884. This species has never but once before been seen and recognized, and then by Weinland, of Boston, in 1858. Both specimens were expelled from young children, and averaged twelve inches in length.

DR. PEPPER also presented the head and neck of a specimen of

TÆNIA MEDIO-CANELLATA.

It occurred in a young man. A course of starving, followed by castor oil and pelletierine, removed a portion of the worm; afterward a repetition of the starving process without the castor oil, but with the alkaloid, brought away the entire worm dead.

Dr. Pepper said he was particularly interested in this series; it spoke forcibly of the necessity of studying comparative pathology. The specimens were very perfect, and more instructive than more highly organized species. In practice he had found the T. medio-canellata as difficult to expel as the tænia solium. The exhibition of the small variety, the flavo-punctata, taught the necessity of careful examination of the stools.

DR. DE SCHWEINITZ exhibited the kidneys, ureters, and bladder from a man who died after the operation of

LITHOLAPAXY.

The patient, æt. 73, had for two years previous to the operation suffered with straining during the act of micturition, and other symptoms of hypertrophy of the prostate gland and vesical calculus. The urine contained albumen, pus, epithelium, and granular casts, and had a specific gravity of 1018. The patient's habits were intemperate. The operation of litholapaxy was performed, marked difficulty having been experienced in the introduction of the instruments.

After the operation the patient exhibited great restlessness, precordial pain, and a rapid, feeble pulse. Later he became comatose, and died twenty hours after the operation, the immediate cause of death being, ap-

Digitized by Google

parently, the formation of a heart-clot. The *post-mortem* examination was made about ten hours after death:

Body well made; nothing of note anteriorly; the usual ecchymoses posteriorly. *Thorax:* Old pleuritic adhesions on the right side; left side free. Lungs crepitant with slight posterior congestion. Heart surrounded with fat; muscular fibres flabby; valves normal; firm "chicken-fat" clot in the right ventricle. *Abdomen:* Position of viscera usual. Marked deposits of fat in the omentum. Liver slightly enlarged, soft, but otherwise normal. Both kidneys granular and containing cysts. Bladder thickened and showing two spots of ecchymoses on the mucous surface. Prostate enlarged; other organs normal. Brain and membranes not examined.

DR. TYSON thought this case added one more to the list showing the impropriety of crushing for stone when kidney disease is present. He did not know why, but under such circumstances the cutting operation is more suitable. Dr. Tyson cited the case of Louis Napoleon as an instance of the danger of crushing in the presence of kidney disease. Dr. Tyson said, in answer to a question of Dr. Barton's regarding the kidneys, that they were contracted, though not markedly so, as there was good secreting structure left. The cysts were part of the pathological anatomy of granular kidney. He believed the cause of death to be uræmia.

DR. DE SCHWEINITZ said that the urethra was not examined, and agreed with Dr. Tyson that the cause of death was uræmia. This was the more probable because an officious attendant, against orders, had administered rather full doses of morphia.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 1, 1885.

THE PRESIDENT, ABRAHAM JACOBI, M.D., IN THE CHAIR.

DR. R. VAN SANTVOORD read a paper on

OBSCURE CASES OF WEAK HEART.

Having alluded to some of the numerous causes of weakness of the heart structure without valvular disease, very prominent among which is typhoid fever, he stated that in many instances a positive diagnosis can only be made after a very careful and thorough investigation of the case.

The first case which he narrated was that of a strong and fresh-looking man, 42 years of age, who had the appearance of robust health. His occupation was that of a drygoods salesman, and except that he took an occasional drink with a customer and ordinarily ate his meals too rapidly, his habits were good. He suffered from drowsiness, which would often come on during the day, and from frequent headache; while his mind was apt to be forgetful. He was also somewhat short of breath in going upstairs, and there was slight disturbance of digestion. The heart sounds (especially the first sound) were rather weak, and there was a distinct reduplication of the second. There was no valvular trouble, and the sphygmographic tracing was of no special significance.

He was placed on ten minim doses, three times a day, of tincture of digitalis and of tincture of nux vomica; the latter being added on account of the digestive trouble. At the end of two weeks the heart sounds were louder, but the general health was not improved. The remedies at first prescribed were then substituted with caffeine and strychnia, and under the use of these last he rapidly recovered. Afterwards, when he felt the drowsiness or headache coming on, a few doses of caffeine soon dispelled the trouble.

The second case was that of a stockbroker, 38 years of age, who came of a gouty family, and had had several attacks of gout himself. He had been much harassed by business anxieties, and for the past four years had been in the habit of indulging very freely in the use of spirits. He was prematurely gray, looking much older than he really was, and altogether exhibited a very haggard and careworn appearance. He complained of shortness of breath in going upstairs, and it was ascertained that he had had some albumen in his urine, with occasional puffiness about the ankles, especially when he drank brandy. He was in the habit of taking from twelve to fourteen drinks of whiskey a day, and eating but one meal during the twenty-four hours. When examined, he was found to be suffering considerably from dyspnœa and wheezing. The first sound of the heart was weak, and the second hard and metallic. The urine was slightly albuminous, and of a specific gravity of 1024. One fatty cast was found.

There was great improvement in his case when he stopped drinking whiskey; but when he began to go about again after resting for a time, the dyspnœa returned. He was then ordered ten minims of tincture of digitalis three times a day, together with appropriate tonics, and in two days he was able to sleep flat on his back throughout the night. At the end of six months he had gained measurably in health and strength, though a small amount of albumen was still detected in the urine by means of the mercuric iodide test, and there was also found a number of hyaline cysts. He had previously been rejected by an examiner for a life insurance company on account of the quickness of his pulse. The cardiac disturbance was unquestionably the predominant trouble in the case, and the existence of grave disease of the kidneys was considered improbable on account of the slight and varying amount of albumen in the urine, the normal quantity of the latter, and other circumstances that were noted. The sphygmogram of the patient was exhibited.

The third case was that of a gentleman 54 years of age, who had always been addicted to athletic sports, and had constantly enjoyed good health with the exception of constipation. For a long time he had been obliged to get up in the night to urinate. He now suffered from headache and drowsiness, and was thin, sallow, and anxious looking. There was found to be considerable dilatation of the left ventricle, and also a faint systolic murmur. The cardiac sounds were weak, especially the first sound, and the urine was albuminous. He sought medical advice on account of an intense pain in the vertex, and insomnia. Bicarbonate of soda and gentian were first prescribed, on the supposition that the headache was due to gastric derangement, but no relief ensued. The patient was then put upon tincture of the chloride of iron with digitalis, and at once there was marked improvement in his condition. From the

Digitized by Google

enlargement of the heart and the great quantity of urine passed, together with the amount of albumen found in the urine, it was inferred that the condition present was one of granular contracted kidney with resulting heart weakness. The sphygmographic tracing of the case was then shown.

After this the patient went to the South for some months. He held his own for a year, and at the end of that time it was found that there was no albumen in the urine, which was of a specific gravity of 1015; the quantity passed in twenty-four hours being seventy ounces. Hence, it was concluded that the polyuria was due to some other cause than granular contracted kidney, and probably of urethral birth, as it was ascertained that the patient had a stricture, which he had contracted thirty years before in the ordinary way. The cardiac feature in this case, therefore, seemed to be of an independent nature.

The fourth and last case narrated was one in which the symptoms were so striking that the trouble could hardly be called obscure. The patient was a boy of fourteen, who had recently recovered from the measles, and he was found to have a loud blowing systolic murmer, with marked venous hum. There was cardiac dilatation present, such as is apt to occur in long-standing anæmia; and the patient's sphygmogram showed a very considerable degree of arterial tension.

Dr. Van Santvoord then passed in review the group of cases described, and made a number of observations in connection with them. As to reduplication of the sounds of the heart, he said that reduplication of either one or the other of them was present in three out of the four patients. He referred to the various hypotheses which had been suggested to account for this phenomenon of reduplication, and expressed his agreement with Bramwell in the opinion that it was probably due to asynchronous action of the ventricles. In the third case there was marked dilatation of one ventricle, and it was not difficult to see how, under the circumstances, such asynchronous action was likely to occur. Apart from speculation, persistent reduplication of the first sound of the heart had been repeatedly noted in grave lesions of the cardiac tissue. Weakness of the first sound of the heart was found in three of the cases. In the second case the second sound was loud, and in the third weak, as the ventricles contracted more gradually in this instance.

He next made some comparisons of the action of digitalis and caffeine on the heart. The latter he had found to slow the action and increase the amplitude and tension of the pulse. It seemed probable that it had a slighter influence upon the vaso-motor apparatus than digitalis, and, at all events, the fact remained that caffeine is sometimes efficient in cases in which digitalis fails to act satisfactorily. He believed it to be a better and safer agent than digitalis in acute diseases where there is cardiac weakness. An eminent French authority had advised that it should be pushed until two grammes were taken daily.

Dr. John C. Peters referred to a case still under observation, of a gentleman over sixty years of age, who had always been careful in his habits, and apparently enjoyed perfect health, though he had some reason to suppose that his system was not sufficiently well nourished. He was taken with acute pain in the epigastrium, and when called to see him, Dr. Peters was astonished at the extraordinary weakness of the pulse and failure of the heart which he found. There was at first slight congestion of both lungs, which was followed by bronchitis and some pulmonary œdema; but the temperature was now above 102° F. Dilatation of the right ventricle, with extreme dyspnœa, rapidly developed, and the patient for a considerable time was in a very precarious condition. Since then he has greatly improved so that he is now able to walk a mile; though the heart still remains weak. He had been treated with the ordinary remedies, and in regard to the use of nux vomica, Dr. Peters remarked that it often seems to act more efficiently than digitalis. Like other observers, he had frequently noticed weakness of the heart in connection with pneumonia, and he had formerly believed this to be due to the formation of a clot in the right side of the heart.

Dr. Leonard Weber said that he had observed no effect from caffeine in cases of dilatation in connection with probable fatty degeneration of the cardiac tissue. He had, however, had good results from the action of digitalis; he had never used the tincture. The infusion, if obtained from perfectly reliable sources, is in every way preferable; but the best preparation of all is undoubtedly Squibb's fluid extract. In delayed recovery of the heart, after acute diseases, he had found caffeine very efficient, and the preparation of it which he is in the habit of using is the hydrobromate. This is generally employed in connection with appropriate tonic remedies. In conclusion, Dr. Weber spoke of the kind of cardiac weakness met with in men of over forty years of age, and weighing more than 250 pounds, where urgent dyspnœa arises from the deposit of layers of fat between the muscular fasciculi of the heart. The successful treatment of such cases is found to consist in the diminution of the amount of liquid taken, the regulation of the food for the purpose of reducing fat, and the employment of as much exercise (principally walking) as can be well borne.

Dr. E. Darwin Hudson remarked that affections of the heart are not a complicated matter. Whatever might be the characteristics of the difficulty attracting attention, he thought that the experienced physician will at first apply all the tests for the detection of the presence of organic cardiac trouble. If after a thorough examination it is found that there are no evidences of organic disease, he should next investigate the condition of the various viscera in turn, commencing with the kidneys, and then passing on to the liver, stomach, and other organs. A very large proportion of the cases of temporary cardiac disturbance are undoubtedly produced by digestive troubles and perversion of assimilation. Especially have these a marked effect in lowering the pulse; so that if a patient comes to us with a pulse of 40, or perhaps only 32, it can be pretty safely predicted that a cholagogue cathartic will promptly bring it up to the normal standard. If, however, no cause for the cardiac trouble can be found in any of the other organs, we should conclude that it is probably due to a derangement of the ganglionic action of the heart itself, from some defect in the blood supply, and for this condition such remedies as digitalis, caffeine, and convallaria are appropriate.

Dr. John P. Garrish called attention to the impor-

Digitized by Google

tance of the prevention of such diseases as constituted the present subject of discussion. The use of tobacco, he thought, is responsible for a very large number of these cases of cardiac weakness. In addition to guarding against the excessive use of this, it is also necessary that the diet should be of proper character (the food being highly nutritious, but not stimulating), and that changes of temperature should be carefully provided against, especially by the wearing of flannel. At the same time the individual should avoid excitement. As to the remedies that are of most service in weak heart, he had obtained very satisfactory results indeed from the combination of tincture of digitalis with tincture of stramonium, as suggested to him by the late Dr. Valentine Mott.

DR. ANDREW H. SMITH said in regard to the use of digitalis, that it performs two distinct functions. In the first place, it affects the cardiac action; and, secondly, when given in small doses, it affects the cardiac nutrition.

DR. FRUITNIGHT stated that some time since he had resorted with success to the use of tincture of the night-blooming cereus in a case of apoplexy followed by softening, in which no effect upon the cardiac weakness present was produced by either digitalis or convallaria. Since then he has employed it repeatedly, and has always found it efficient. The dose is from three to ten minims.

DR. VAN SANTVOORD closed the discussion, and in the course of his remarks he spoke of the case which Dr. Peters had described as being one of great interest and instruction. It seemed to him probable that in this instance the cardiac weakness had existed for a long time, but it was only when the acute attack spoken of came on that the heart proved inadequate for its work. Under ordinary circumstances it was competent to meet the demands made upon it, but it was not able to stand the extra strain thus imposed upon it. Dr. Hudson had pointed out very clearly in his remarks the manner in which these cases should be studied; but he had reason to believe that the difficulty is not recognized as it should be by the mass of general practitioners, and it was on this account that he had prepared his paper.

NEW INVENTIONS.

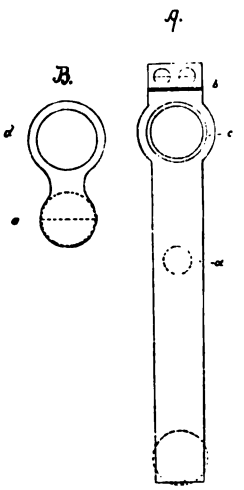
SOME ADDITIONS TO THE OPHTHALMOSCOPE.[1]

BY B. ALEX. RANDALL, A.M., M.D.,

OPHTHALMIC AND AURAL SURGEON TO THE EPISCOPAL AND THE CHILDREN'S HOSPITALS, PHILADELPHIA.

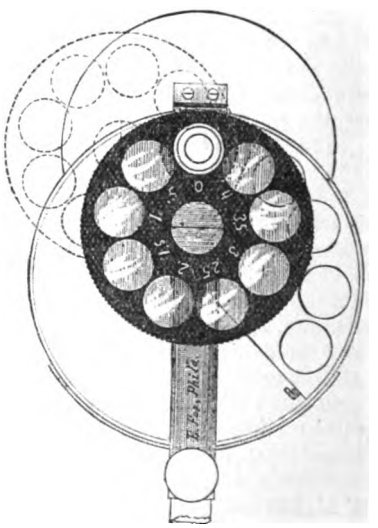
Cylindrical Lenses. Anyone who makes much use of the ophthalmoscope not infrequently meets cases where cylinder glasses in the ophthalmoscope would be of service. Of course, the desired lens can be taken from the test-set (if at hand) and placed behind the mirror, and some instruments, like that of Noyes, are fitted with a spring-catch to hold it there; yet such an arrangement is but bungling at the best, and the mounting of the Rekoss disk is demanded for these as well as for the spherical lenses. The adjustment for the direction of the cylinder axes made use of by Parent in his earlier ophthalmoscope seems the most satisfactory, and has been adopted with little modification in the arrangement here set forth. That such an arrangement has not been well received heretofore, probably depended more upon the other qualities of the instrument of which it formed a part; and the writer's cardinal principle of construction has been that the addition should be made applicable to the ophthalmoscope of Loring with little or no change in the size, weight, or balance of that unequalled instrument. A description will render easy the understanding of its working and its mode of adjustment to the new form of the Loring ophthalmoscope, for which it is more especially designed.

FIG. 1.



The solid covering quadrant which bears the pivot for the Rekoss disks of the original instrument is re-

FIG 2.



placed by a piece of metal of the form figured at *A*, bearing the pivot (*a*) as before, and extending up to be fastened by its shoulder (*b*) to the body-plate of the

[1] Both additions are constructed by E. Fox, Optician, Seventeenth and Chestnut Streets.

Digitized by Google

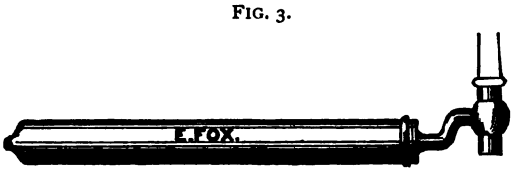
instrument above the lenses. Concentric with the sight-hole of the ophthalmoscope, this is widened and supports a short tube (*c*). Moving upon this tube by a collar fitting *d*, is a short arm (*B*), having at its other end the pivot (*e*) on which turns the disk of cylindrical glasses. This disk (Fig. 2) contains nine openings—one empty, the rest holding *concave* cylindrical lenses in the following order: 0.5, 1, 1.5, 2, 2.5, 3, 3.5, and 4 dioptres. The axis of each lens is at right angles to the radius of the disk passing through it, or, what amounts to the same for the lens at the opening, at right angles to the line of the arm on which the disk is carried. When, therefore, this arm is directed downwards, as in the cut, the cylinder-axes are horizontal as the glasses come into position at the sight-hole of the instrument; and, as the axes of concave cylinders are generally required at or near the horizontal, this is the position which the disk will most frequently occupy in use. Combination with the underlying convex spherical lenses will give the equivalent of any *convex* cylinder desired, either alone, or in combination with a spherical; while, of course, any concave spherical can be added to any cylinder—*e.g.*, — 1 cyl. axis 180° ⊃ + 1 sph. = + 1 cyl. axis 90°; — 1.5 cyl. axis 180° ⊃ + 3 sph. = + 1.5 sph. ⊃ + 1.5 cyl. axis 90°; — 3 cyl. axis 180° ⊃ + 1.5 sph. = + 1.5 cyl. axis 90° ⊃ — 1.5 cyl. axis 180°; etc.

The arm bearing the disk of cylinders can be rotated to any extent desired, and the axis of the cylinder at the sight-hole thus turned to any given direction (*e.g.*, to be vertical when the disk is in the position indicated by the dotted lines), the disk revolving equally well in all positions and furnishing the cylinder of the strength required. A spring-stop serves, as with the disk of sphericals, to centre each lens accurately before the opening. The large head of the screw (*e*) which forms the pivot for the cylinder-disk, is so placed that its cleft marks the direction of the axis of the cylinder which is at the sight-hole.

The maximum addition to the thickness of the instrument due to the new disk is about 2 millimeters (7.75 : 10); the addition to the weight, 3 grammes (48.6 : 51.8); figures which can probably be reduced without sacrifice of either rigidity or durability; the change in its centre of gravity and balance is hardly appreciable. The modification of the original instrument is, therefore, very slight; but one or two drawbacks should, in fairness, be pointed out. The main disk of the instrument is wholly untrammelled in its working; but the supplemental quadrant (indicated in outlines in the cut) is somewhat affected. It loses its covering quadrant and the questionable benefit of its protection; and the pin projecting from its surface, as now made, to facilitate its movement, cannot pass the sight-hole of the instrument—indeed, it engages the new adjustment before the 0.5 lens, which is adjacent to it, comes into position at the opening. This is easily met by a readjustment of the pin, as shown in the drawing, and is completely avoided in the new arrangement of these lenses which the writer has in contemplation. Without change, it proves no actual inconvenience in working to those who, like the writer, make much use of the + 0.5 lens, but little or none of the — 0.5. More important to one whose use of the instrument has not yet given him a sort of instinctive knowledge of what lens he is using, the numbering of the lenses is somewhat hidden, and a rearrangement of these figures would be necessary to show at first glance what lens or lenses are at the sight-hole. To those for whom the addition is especially designed, ophthalmoscopists who have and know the Loring instrument and wish to add to its conveniences, these drawbacks will not be great. Those who have not yet learned the instrument and given it the warm appreciation it deserves, may find certain advantages in a more modified form which the writer will bring forward as soon as actual work shall have confirmed the value of the theoretical improvements which it embodies. The cylindrical disk can be made detachable, and laid aside when not desired; but it would be at some sacrifice of lightness, strength, and smoothness of working.

An "Artist's Attachment." The difficulties of sketching the appearances of the eyeground are considerably increased, and the slowness of accurate portrayal largely augmented, by the need of laying down the ophthalmoscope in order to give both hands to the drawing. "Artists' ophthalmoscopes" carried upon a brow-band have been designed to meet this, and are doubtless valuable; but either their simplicity limits their usefulness from the small number of lenses at command, or else their cost narrows their use. In drawing, too, more than at other times, astigmatism is apt to be much in the way, and demands correction by cylindrical lenses—in the instrument, if possible. The ideal means of meeting all or the most of the difficulties is so to arrange that any ophthalmoscope which is at hand, however complex, may be employed, and yet both hands be left free; and the simpler and less expensive the means to this end the better. Such a means is afforded by a wooden "handle" to be held in the mouth,[1] of oval section, about six centimeters in length by one centimeter in thickness, covered by a bit of rubber tubing.

FIG. 3.



This has at one end (with or without the "goose-neck" represented in the cut) a ball of brass through which slides the short cylinder into which, in lieu of the ordinary handle, the ophthalmoscope is screwed. Most ophthalmoscopes (Loring, Knapp, Gowers, etc.) unscrew at about seven centimeters below the sight-hole, a distance closely approximating the average difference of level of the eye and the mouth. The exact adjustment for any instrument and observer is readily given by the sliding of the cylinder through the ball or by the bend given to the "goose-neck." The amount of control over the instrument which can be conveniently exercised by the mouth, will probably surprise those who employ this simple attachment.

[1] A somewhat similar arrangement is used by Prof. Politzer for his ear-mirror.

CORRESPONDENCE.

TRAINING SCHOOL FOR NURSES.

To the Editor of THE MEDICAL NEWS.

SIR: I take pleasure in sending you the accompanying statistical table regarding the practical working of training schools for nurses.

Although this table is dated 1883, I am not aware of anything similar on the subject bearing upon the same points. I believe that there are hospitals away from the cities named in the tables, large enough to support training schools, and which would do so if they were convinced that these are entirely practicable and efficient.

Hoping the table may prove of value to your readers, I remain

Very truly yours,

WALTER B. PLATT.

165 PARK AVENUE, BALTIMORE, October 9, 1883.

Table of Statistics of Several Training Schools for Nurses, in their relation to their Hospitals and to each other, prepared that the friends of the Connecticut Training School may at the close of its Tenth Year understand its position as compared with similar institutions elsewhere.

DECEMBER, 1883.	No of T. S. Nurses, not including Supt.	Average No. patients under T. S. care.	Average to each Nurse.	Cleaners *attached* to each ward.	Men Nurses each ward.	Do T. S. Nurses dress wounds in men's wards?	Are maternity cases received?	Do T. S. Nurses care for male Erysipelas patients in isolating wards?	Does Hospital bear all expenses of School?	Yearly average of T. S. salaries paid by Hospital.	Does the Supt. of Hospital think the T. S. valuable to the Hospital?	Does he know of any as good and cheaper plan?	How long is Hospital course?	Does School send Nurses out to private families the 2d year?
MASSACHUSETTS GENERAL HOSPITAL,	53	170	3 1/53	1	For the Hospital 6	Under the direction of House Staff or Assistants to them.	No	"No such wards. Nothing like an epidemic for 7 years." About 2 weeks' nursing yearly.	Board, lodging and washing, and part salaries.	$3,527.33	"No Hospital of any size is complete without one."	"Any other system inferior in every respect."	2 years.	No.
NEW YORK, 15th St.,	36	140	3 32/36	1	1	No.	No	No rule. Sometimes.	Entire.	About $5,700.00	"In all its developments and departments good only and always good."	No.	18 mos.	No.
HARTFORD,	16	94	5 14/16	2 for the Hospital.	2	Yes.	Yes	Sometimes, or Hospital hires extra help.	Entire.	About $1,962.00	"Decidedly."	"All things considered, no."	1 year.	Yes.
MT. SINAI, New York,	19	75	4	In women's wards 1 men's 2	3 no women.	No women nurses in any such wards.	No	No T. School nurse is employed in *any* such ward.	Salaries partly.	Not ascertained.	"Great benefit but expensive."		1 year.	Yes.
BELLEVUE,	50	260	5 10/50	1 or more if needed.	1	In one of them.	No	Only for women.	Salaries and washing partly.	$6,722 00	"Certainly I do."	No.	1 year.	Yes.
BOSTON CITY HOSPITAL,	61	286	4 42/61	1 woman with an assistant in every ward. 21 men Nurses and cleaners in addition		Yes.	No	One ward. 26 beds contagious diseases. 12 nurses and 1 cleaner.	Entire expense.	$8,820.00	"Yes."	"The cheapest and best."	2 years.	No.
NEW HAVEN,	22[1]	112	5	Partial services of one woman in each women's ward. One man who acts as Nurse and also cleans in each men's ward, with occasional help.		Yes.	Yes	Always for men and women. Isolating wards open for the care of Erysipelas a large part of the months of Feb., March, April, May, June, Oct., Nov., and Dec.	Board, lodging and washing.		I do.	Not that I know of.	1 year.	Yes.

1 One additional pupil is detailed to kitchen service, simply a duty not performed by other Schools.

It will be noticed that the New Haven Training School has been conducted with *less help* from Hospital servants, and at *less expense* to the Hospital with which it is connected than any other institution mentioned.

THE STUDY OF OBSTETRICS IN PRAGUE.

FROM the moment the English-speaking medical student puts foot on Continental soil, he hears the most varied and conflicting reports of the advantages of

Digitized by Google

Prague as a place to study and pursue practical obstetrics. He hears that he can live comfortably in the hospital for a "mere song," and that opportunities are afforded him to perform "all the operations." But he occasionally hears these statements contradicted in the very strongest terms. It may, then, be of some value to the American student intending to take the Continental trip to be told in plain terms what opportunities for the study of obstetrics really exist in Prague.

The Gebärhaus is a fine, irregular pile of brick buildings, freely ornamented with a steeple over the "Baptismal Chamber," giving to the whole rather a monastic and religious appearance. The building is quite new,—four or five years,—the wards being lofty, clean, and well ventilated. Since the rupture between the German and Bohemian citizens, some three years ago, the institution has been divided into three equal parts. One under German control; one under Bohemian, and one for the training of nurses, which, also, is under Bohemian control. Each division is quite independent of the other, and admits cases in regular rotation. The number of births ranges from 2700 to 3000 yearly, so that each division has from 900 to 1000 cases annually. It is to the German division that foreign students generally go, hence to this I will confine my future remarks.

The vacation months, April, May, August, and September, are usually chosen, as at this time there are no junior students attending. Dr. Fleischman, Prof. Breisky's first assistant, a very zealous and able teacher, gives two courses, each of four weeks' duration, during each of the vacations. The course consists in digital and external examinations of pregnant women, usually in the last week of pregnancy, combined with external measurements by Baudelocque's pelvimeter, and the various obstetrical operations on the phantom. The fee for the four week's course is 25 *fl.*—$10; in addition to this, one is obliged to pay 10 *fl.* for permission to live in the maternity and "practise." It is, particularly, in relation to the latter that the most diverse statements obtain.

From extended inquiries, and personal experience within the hospital, I am enabled to define "practice" as the mere privilege of examining women in labor, according to a definite system. Three men are allowed to examine the same case, provided it is a normal one, and only the first man on the list is allowed to make further examinations during the course of the labor. The nurses, who, by the way, are very efficient, deliver all normal cases, the assistant being sent for only in cases requiring operative interference. This he always does himself, and no member of the class is allowed to put on the forceps, contrary to the impression that generally seems to prevail. It is considered quite a stroke of good fortune if one gets an opportunity of supporting the perineum and passing the catheter once.

Strict antisepticism is carried out to, perhaps, what may appear a ludicrous extent. After one has handled the "alcoholic fœtus" used in the operative course, he must take a tub-bath, and change his underclothing, before being allowed to "practise." Prior to making a digital examination the hands and forearms must be well scrubbed, then bathed for five minutes in a corrosive sublimate solution (1 to 2000), rinsed with pure water, and dried. The statistics, which are among the best on record (mortality a trifle over ¼ per cent.) seem to justify these precautionary measures. But the nurses and assistants have suffered, far more than once, from slight attacks of salivation by this free use of the sublimate in ablution.

Nature is interfered with as little as possible; the forceps are very seldom applied—not more, I think, than once in fifty cases. Every tear, no matter how insignificant, is carefully sewed with catgut uninterrupted suture. This is done from an antiseptic point of view, so as not to leave any abraded surface which would favor absorption of the decomposing discharges. As may be expected, the number of abnormal cases varies at different periods. But during a four weeks' course a couple of turnings, as many forceps applications, a few cases of eclampsia, and a craniotomy may be safely expected.

The living accommodations in the hospital are wretched. A large, dirty ward, with beds arranged on either side to the number of twenty, is consigned for this purpose. Two long deal-tables, with several broken chairs, and a couple of wardrobes, comprise the whole furniture of the "barracks," as it has been truly named. A single sink serves for all ablution requirements. Organisms that are not microscopic, with very ferocious appetites, abound in as great numbers as "microörganisms" in the object-field of a German microscopist. Let ten or twelve men from all parts of the universe, with the diverse toilet and other habits that pertain to such a motley collection, occupy the "barracks," and fancy the floors covered with a couple inches of dirt, let dirt meet the eye in whichever direction it turns, and a fair idea will be gained of the "comfortable residence" provided for in the hospital. It is not practicable to live in rooms outside. There is an isolated double room to be had in the hospital, but strangers are usually too late to obtain this luxury. To a green graduate, who, perhaps, has never made a digital examination, a four weeks' course in Prague, despite the personal inconveniences, will doubtless be of considerable benefit; but any one coming to the Continent for the purpose of familiarizing himself with the various obstetrical operations had better seek another field. H. N. V.

PRAGUE, September 21, 1885.

NEWS ITEMS.

WASHINGTON.

(*From our Special Correspondent.*)

CHOLERA AND TYPHOID FEVER IN MARSEILLES.—Consul F. H. Mason has forwarded to the Department of State the following report describing the progress of the epidemic of cholera in Marseilles: Since the date of his last communication on that subject the outbreak of typhoid fever at Marseilles and its causes, and the measures which have been proposed by the French Government to improve the sanitary condition of Marseilles and Toulon, since the 26th of August, the last day included in the latest report of this series, the daily cholera death-rate, as well as the total mortality from all causes, at Marseilles, has steadily subsided. The deaths from cholera have been numbered by days, 31, 28, 27, 24, 28, 25, 20, 12, 11, 11, 10, 16, 8. Total 251, or a daily average of 19⅓. The total deaths from all causes during the same period have been 85, 65, 67, 58,

Digitized by Google

55, 45, 54, 52, 41, 38, 56, 54. Total 683, a daily average of over 56, or about the normal death-rate of the city. The total number of deaths during August was 2311, which is only 167 less than the record of July, the most fatal month of 1884. Meanwhile, the cholera has continued to spread throughout the villages and communities of this district, Nîmes, Cette, Aubagne, St. Marcel, and Salon, being among the more important of the towns attacked.

In various instances the transmission of the disease from one place to another has been the result of gross carelessness. The first fatal case at Arles was that of a workman of that city, who, having attended the funeral of a relative who had died of cholera at Salon, brought back the soiled clothing of the deceased. Nîmes ascribes its first case to a resident who attended the funeral of his father, who had died of cholera at Toulon. These examples are mentioned merely as evidence of the danger which is incurred by a person coming from a pure atmosphere into an infected one, and the importance at such times of isolating, as far as possible, houses and communities in which the malady prevails.

At Marseilles, the cholera has gradually assumed a more benign type, so that, at present, more than a majority of the cases are saved. This improvement is also attributed, in some degree, to a change in the treatment of the disease by most local physicians, who, dismayed by the fatality of the scourge during the early days of the epidemic, have since more or less abandoned the copious use of opium and other powerful drugs, which in many cases left the patient, after the initial vigor of the cholera had been overcome, weakened, and doomed to the fatal typhoid stage which follows excessive medication.

Camphor is one of the most essential elements in the new treatment.

Another interesting fact in the pathology of this epidemic was observed on the 20th and 21st of August, the two most fatal days of this year's visitation. The weather, which for six weeks previously had been intensely warm and sultry, became on the evening of the 19th cool and fresh. A strong, dry, refreshing breeze blew from the west-northwest during the next two days, and during those days the deaths from cholera numbered sixty-two and sixty-nine respectively. So far as is known every case of cholera which occurred during that period was fatal. Every method of treatment seemed alike futile; and the victims included numerous persons living in good estate, and who had committed no imprudence. The well-known bad effect of chill would explain some of this fatality, but it will not explain the malignity of other cases in which the victims were warmly clad and protected from all exposure. We are therefore driven back to the theory that the wind which prevailed at the time diminished the proportion of ozone in the atmosphere, which, as was shown last year, affects directly the fatality of cholera. During the epidemic of 1884 some experiments were made at the Pharo Hospital, in which a certain ward was supplied with ozone artificially generated by an electrical machine. The result was favorable, but the experiment was not conclusive for the reason that the machine was small, and the quantity of ozone supplied was therefore insufficient. Similar changes of weather at Toulon have this year been followed by the same increased mortality, so that the ozone problem may be regarded as offering a field for valuable study.

A Scourge of Fevers.—At Marseilles, the exaggerated total death rate has been largely due to a continuance of the typhus and typhoid fevers, which have prevailed in some streets and precincts with alarming malignity.

At Sainte Marthe, a village which forms one of the northern suburbs of this city, there have been within a few days twenty deaths from typhoid fever among a population of less than 1400 people. The outbreak there is explained by the statement, that when the military camp at Pas des Lanciers, a few miles north of this city, was broken up in August by the fatal epidemics of fevers which compelled that resource, the blankets of the invalid soldiers were brought to Sainte Marthe and cleansed in a public "lavoir," where the linen of the entire village is washed. It is stated in defence of this extraordinary proceeding, that the bedding had been disinfected before being washed at Sainte Marthe, but the results seem to prove that the disinfection was not effective. Here again is a lesson to enforce: the importance of the rigid precaution in the treatment of textile materials coming from a district tainted with any contagious or infectious diseases. The commercial strictures which are so often seen and heard against the United States Government, for what is termed the needless severity of its regulations concerning the importation of rags from Mediterranean ports, betray a curious ignorance of this subject. When it is considered that, throughout almost the whole of Spain, and more than a hundred towns and villages of Southern France and Italy, cholera now exists or has existed during the present summer, that this disease, as well as typhus and typhoid fevers, is easily communicated by clothing and bedding, and that not only are the strictest regulations insufficient to prevent ignorant and avaricious people from concealing and selling the clothes and bedding of deceased relations, but that it is practically impossible in most cases to establish the exact origin of rags in the market of a large port like Marseilles; the importance of thorough disinfection of all rags from these countries must be admitted.

At Toulon, the cholera has been, as already reported, much more severe, relatively, than at Marseilles, though the course and type of the disease, its complications with typhus and typhoid fevers, and its increased fatality under certain cool, dry winds, have been exceedingly similar.

Of the 65,000 inhabitants of Toulon probably a third have left the city, and a large proportion of its shops and stores are closed.

Since the 27th of August the deaths from cholera among the diminished population have been, by days, as follows: 42, 27, 25, 15, 23, 9, 26, 23, 22, 16, 10, 11, 7. Total 256 choleraic deaths out of a total mortality of 331.

An incident worthy of record at Toulon, was the case of a gardener named Gherci, who, being at the hospital Bon Neucontre, in the final algid stage of cholera, cold, blue, and nearly pulseless, was left by the attendants as dying. Bottles of hot water had been packed around the sufferer in the hope of restoring his vital warmth, but in vain. The poor fellow, left to his own resources, managed to uncork and drink the contents of two of these bottles. This inward application of heat restored the vital current and his life was saved.

Digitized by Google

The lesson of this summer has been a severe one, not only to Marseilles and Toulon, but to the whole of France, whose prosperity has been vitally injured by the recurring epidemic, which, as is now plainly seen, might and ought to have been prevented. The French government is now thoroughly aroused to this constant menace on its southern coast, and during the past week the Minister of the Interior, M. Allain Targé, has paid a visit to both the stricken cities, to see and report officially what needs to be done. The necessities of the case are sufficiently plain, and the official report of the Minister states with clear conciseness what is to be done.

At Marseilles: 1. To construct two large transverse sewers to receive and discharge the entire sewerage of the city in deep water outside the ports.

2. To demolish and rebuild that part of the city in rear of the Bourse, and to open wide streets through the old and densely built quarters.

At Toulon: 1. To build an entire sewer system, which shall discharge into the open sea.

2. To open wide streets through the eastern part of the city.

3. To rebuild the fortifications in the same quarter, and remove entirely the encircling wall which now excludes air and light; and

4. To provide a complete water supply.

These are serious and costly measures, far beyond the unaided power of either city to undertake. Toulon is a great naval and military station with little seaward commerce or local trade except what is incident to the Government service. Marseilles, with her vast commerce crippled by the quarantines of those two unfortunate years, and her resources exhausted by the costly works undertaken since 1850, her waterworks, sewers, and pavements, is similarly unable to meet alone the cost of what remains to be done.

The Suez Canal, which has done so much for international commerce, has at the same time put Marseilles into direct relations with the permanently infected parts of Southern Asia.

The French operations in Cochin-China, the constant stream of invalid soldiers returning in crowded ships from service in those pestilent climates, have done the same or worse for Toulon. Both cities are radically defective in sanitary construction, both are exposed to constant and extraordinary dangers from abroad.

It is now believed that the Government will help Marseilles and Toulon because it must. The loss to France through cholera in June, 1884, is counted by millions, and the thousands of lives that have been sacrificed emphasize the demand that these twin nurseries of pestilence, shall be cleansed and raised to a modern standard of sanitation.

Professorship of Surgery in Georgetown University, D. C.—At the time that Surgeon-General Hamilton, of the United States Marine-Hospital Service, handed his resignation to the President, he also resigned the Professorship of Surgery in the Medical Department of the Georgetown University, D. C. It was accepted with reluctance, and ex-Surgeon-General Philip S. Wales was finally appointed to the vacancy. When it was ascertained that the President would not accept the resignation of the Surgeon-General, Dr. Wales immediately tendered his resignation of the Professorship, and Dr. Hamilton was reëlected to the Chair, and has begun his lectures.

MONTREAL.

(*From our Special Correspondent.*)

Medico-Chirurgical Society.—The election of officers for 1885–86 took place at the annual meeting held on Friday, October 9, with the following result:

President.—Dr. T. G. Roddick (reëlected).

Vice Presidents.—Dr. I. C. Cameron, Dr. George Wilkins.

Treasurer.—Dr. Perrigo.

Secretary.—Dr. Gurd (reëlected).

At this meeting a resolution was passed endorsing previous resolutions passed from time to time by the Society regarding the great efficacy of vaccination as a protection against smallpox, and the necessity of revaccination in such times as the present, when smallpox is so prevalent.

Medical Schools.—Notwithstanding the smallpox, the medical schools have nearly as many students as in previous years. The McGill Medical School has a large entry of new men, and the classes are being held in the new building. The formal opening will take place on Thursday, October 22, when it is expected that several distinguished medical and lay men from a distance will deliver addresses. Professors Pepper and Osler, of Philadelphia, have promised to be present, and also Sir A. T. Galt and Sir Charles Tupper, M.D., K.C.M.G.

The Smallpox Epidemic.—At last the Provincial Board of Health has given orders to enforce the Compulsory Vaccination Act. The result has not been as brilliant as expected, for the local Board of Health has as yet done nothing to carry out the orders of the Central Board. There has certainly been some house-to-house visitations in the Western and English portions of the town, but this section had already been thoroughly vaccinated and revaccinated. I hear of no attempt being made by the health authorities to enforce the Compulsory Vaccination Act in the quarter of the city which needs it most, viz., St. Louis, St. James, and St. Mary's wards, occupied principally by French. The riots which took place here lately were merely a public manifestation of the feeling of the unvaccinated, and not the result of an attempt to enforce the Act. The East End Health Office which was wrecked has not yet been reopened. The opposition to vaccination among the French people is due, not only to social and religious prejudices, but to a large extent, I am sorry to say, to the bigotry and ignorance of many of the medical men, who, though publicly approving of vaccination, secretly denounce the practice as useless always and dangerous, especially in times when smallpox is epidemic. The medical men who act thus belong to a certain medical school in this city, which has a man occupying one of its most important chairs who for years has preached against vaccination, and who, like most anti-vaccinationists, is a fanatic on the subject.

The new smallpox hospital is now ready, and in it will be room for some five hundred more patients. The old hospital was much overcrowded, and could not take

Digitized by Google

in half the people who applied for admission. Now every person affected with smallpox, who declines to go to hospital has his house quarantined. Persons are not allowed to enter or leave the house during the period it is infected. Manufacturers, companies, and firms employing a number of people, have enforced vaccination, not only on their employés, but their families. Any employé declining to have his family vaccinated is immediately dismissed; thus large numbers of people are vaccinated who could not be reached in any other way. In many large establishments the workmen (French) have left in a body; but, after a day or two of reflection, have returned and submitted themselves and their families to vaccination.

The number of deaths from smallpox last week was nearly 300. About 80 per cent. of these were children under 10, and 90 per cent., French Roman Catholics. Last month, in this city, 697 died from smallpox, and in the suburbs about 150; total, nearly 850.

MORE RESIGNATIONS FROM THE CONGRESS.—Dr. Henry F. Campbell, of Augusta, Georgia, has declined the Vice-Presidency of the Congress.

Dr. E. O. Shakespeare, of Philadelphia, has resigned the Presidency of the Section of Pathology.

Dr. Henry G. Beyer, U. S. N., and John J. Mason, of Newport, have declined to serve on the Council of the Section of Physiology. Dr. Jerome N. Kidder, of Washington, has declined to serve on the Council of the Section of Public and International Hygiene. Dr. J. M. Flint, U. S. N., on the Council of the Section of Practical and Experimental Therapeutics.

THE AMERICAN ACADEMY OF MEDICINE will hold its next annual session at New York, on October 28 and 29, 1885.

OBITUARY RECORD.—Died, of pulmonary consumption, at his home in Baltimore, on Wednesday, October 7th, RICHARD MCSHERRY, M.D., in the 68th year of his age.

Dr. McSherry was born in Martinsburg, Va., in 1817, graduated from the medical school of the University of Pennsylvania in 1841, entered the army and served under Taylor in the Seminole War. In 1843, he became an assistant surgeon in the U. S. Navy, and saw active service in the marine corps under Scott in the Mexican campaign. Resigning his commission, he came to Baltimore in 1851, and entered upon the practice of his profession. In 1862, he was called to the chair of Materia Medica and Therapeutics in the University of Maryland, and in 1865 was transferred to that of Practice of Medicine, a position which he filled until his death. He was one of the founders and the first President of the Baltimore Academy of Medicine, and President of the Medico-Chirurgical Faculty for the year 1883.

Dr. McSherry was a facile writer and contributed many articles to the medical press, and even at his advanced age devoted himself with assiduity to literary pursuits. Among his publications may be prominently mentioned his excellent manual of hygiene, entitled *Health, and How to Promote It*, and an interesting sketch of military and civil life in Mexico, called *El Puchero, or a Mixed Dish from Mexico.*

A man of irreproachable character and scholarly attainments, a dignified and courteous gentleman of the old school, a wise and conservative teacher and practitioner, a devoted husband and father, and a faithful friend, Dr. McSherry will be long remembered not only by the profession of his State, but also by the many friends in other walks of life whom he endeared to him by his genial manners and his guileless heart.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM OCTOBER 6 TO OCTOBER 12, 1885.

ADAIR, GEO. W., *Captain and Assistant Surgeon.*—Leave of absence extended one month.—*S. O. 232, A. G. O.*, October 9, 1885.

WINSEL, DANIEL, *Captain and Assistant Surgeon.*—To be relieved from duty at Camp at Rock Springs, Wyoming Territory, and return to his proper station, Fort Fred. Steele, Wyoming Territory.—*S. O. 99, Department of the Platte*, October 1, 1885.

BIART, VICTOR, *Captain and Assistant Surgeon.*—Sick leave of absence further extended six months, on surgeon's certificate of disability.—*S. O. 227, A. G. O.*, October 3, 1885.

BUSHNELL, G. E., *First Lieutenant and Assistant Surgeon.*—Granted leave of absence for one month.—*S. O. 215, Department of the East*, October 6, 1885.

STEPHENSON, WM., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort Niobrara, Nebraska, and ordered for duty at Camp at Rock Springs, Wyoming Territory.—*S. O. 99, Department of the Platte*, October 1, 1885.

CHAPIN, A. R., *First Lieutenant and Assistant Surgeon.*—Leave of absence extended one month.—*S. O. 230, A. G. O.*, October 7, 1885.

MORRIS, EDWARD R., *First Lieutenant and Assistant Surgeon.*—(Recently appointed) ordered for duty in Department of Missouri.—*S. O. 233, A. G. O.*, October 10, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING OCTOBER 10, 1885.

BRIGHT, GEORGE A., *Surgeon.*—To United States Steamer "Brooklyn."

FITTS, HENRY B., *Assistant Surgeon.*—To Naval Hospital, New York.

HALL, JOHN H., *Passed Assistant Surgeon.*—Detached from Naval Hospital, Mare Island, California, and ordered to the "Hartford."

SWAN, ROBERT, *Passed Assistant Surgeon.*—Detached from Naval Hospital, New York, and ordered to the "Brooklyn."

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING OCTOBER 10, 1885.

BAILHACHE, P. H., *Surgeon.*—To proceed to Tuckerton, New Jersey, as Inspector, October 7, 1885.

AUSTIN, H. W., *Surgeon.*—To proceed to Albany, New York, on special duty, October 6, 1885.

GASSAWAY, J. M., *Surgeon.*—To examine surfmen at Ellsworth, Maine, and other ports of First District Life Saving Service, October 9, 1885.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

VOL. XLVII. SATURDAY, OCTOBER 24, 1885. No. 17.

ORIGINAL ARTICLES.

HERNIAL PROTRUSION OF THE MUCOUS MEMBRANE OF THE TYMPANIC CAVITY, THROUGH THE MEMBRANA TYMPANI, IN SOME CASES OF CHRONIC PURULENT OTITIS MEDIA.

BY CHARLES H. BURNETT, M.D.,
PROFESSOR OF OTOLOGY IN THE PHILADELPHIA POLYCLINIC, ETC.

SOMETIMES there may be observed a protrusion of the mucous membrane of the promontory, through a perforation of the membrana into the fundus of the external auditory canal, in cases of chronic purulent otitis media.

The chief interest and importance of these cases consist in the resemblance of the protrusion to granulation tissue, or to a small polypus, and the possible mistaking it for such formations. There are, however, some distinguishing features connected with the hernial formation which will enable the observer to make a correct diagnosis. The hernia of the mucous membrane is sensitive to the touch, forms suddenly, does not bleed easily upon being touched, but bleeds profusely if wounded, and yields quickly to the proper treatment, which, however, is quite different from that applicable to granulations or to polypi. The latter are not sensitive, bleed easily, as a rule, upon being touched, and are snared off or cauterized without pain. Granulations may be made to disappear by the application of powdered borax in cases where they are small, or by cauterants if larger. Hernia of the mucous membrane of the tympanic cavity is made worse by any endeavor to snare it off, or to cauterize it.

It closely resembles, in appearance, a polypus with a broad base, but can be properly treated in two ways only, first either by the application of powdered boric acid, or boric acid and alum in the proportion of ten grains of the latter to one ounce of the former, or by the instillation of absolute alcohol.

The discharge attending it is usually slight, and of a thick, purulent nature. There is no tendency to spontaneous bleeding from the protruding mucous membrane, though I have observed it exhibiting a tendency to recur at the menstrual epoch in women. It is also worthy of note that this affection of the tympanic mucous membrane has been observed by the writer only in women.

At present I have under observation a case of hernia of the tympanic mucous membrane in a lady 35 years old. It seems to have been consequent upon an acute process in the middle ear, from the entrance of sea water while bathing. The disease which followed, perforative inflammation of the middle ear, was neglected, and finally improperly treated for a year after its occurrence. The ear was then found to present the above described hernial protrusion of the mucous membrane of the middle ear, with a slight, purulent discharge, and the hearing was reduced to nearly nil. One or two applications of powdered boric acid, and calendula arrested the discharge, the hernia receded, and the edges of the perforation in the partition and upper part of the membrana became visible. The mucous membrane in the drum cavity became smooth and pale, and the hearing improved slightly. These appearances and conditions remained until a subsequent attack, when the hernia again reappeared. Subsequently, upon several occasions, sometimes upon the patient's taking cold, and again near the menstrual epoch, without any apparent cause, the ear, without pain, began to feel stopped, and in twenty-four hours from these symptoms, enough purulent matter was formed in the canal to block it from the fundus to the meatus, but not enough to run out. Upon removing this, the protrusion of the mucous membrane of the tympanic cavity was seen to have occurred through the perforation in the membrana. All the symptoms subsided upon the application of the above named treatment.

The attacks have finally become less frequent, of shorter duration, and the hearing has improved decidedly, so that words can be heard six or eight feet. Latterly alcohol instillations have been made in this case with marked and further benefit to the mucous membrane of the entire drum-cavity.

Upon an occasion, this patient, when absent from home, applied to another physician for relief from one of these attacks. He unfortunately was not acquainted with the nature of the case, mistook the hernia for a polypus and endeavored to snare it off. The operation was very painful, produced faintness and dizziness in the patient, the hemorrhage was considerable, and an otitis externa of several days' duration was thus set up. Nitrate of silver applications are also resented by these protrusions of the mucous membrane. Its application is also painful, while instillations of alcohol are not. I have seen only two or three such cases, but the peculiar liability to be mistaken for polypi or polypoid growths, as well as their resentful demeanor to the treatment applicable to true polypi or granulation, has induced me to record my experience with them.

THE GERM THEORY OF HEALTH.

BY EZRA M. HUNT, M.D.,
OF TRENTON, N. J.

WE have had good occasion for many years past to hear much of the germ theory of disease. So soon as the microscope confirmed the earlier observations of Boehm, Hallier, Mitchell, Cowdell, and others, it came to be recognized that the air teemed with life, either in animal or vegetable forms, and

Digitized by Google

that human life depends very much upon its power to hold its way among the vast resources of being, either as helped by other life, as resisting or overcoming it, or as having capacity to adjust itself thereto. Even when it came to be known how much of this life is vegetable, it was hard to disabuse the mind of the animal idea, so that now many a tyro "germist" is looking most for animalculæ.

Harder still has it been to get rid of the idea that the germ theory or hypothesis is one of disease and has nothing to do with health. This is very natural, since most of the investigations have had as their point the finding out of the relations of microbes as causes of disease. Growth by fission, and growth by spores, were alike examined to see how the multiplication tended to evolve or to destroy animal life. Hence in our search for the evil genii we do not often remind ourselves

"that these organisms and their spores are found almost everywhere in nature in enormous numbers. . . . The surface of the animal body is covered with them, and in the mouth and parts of the alimentary canal they flourish in great luxuriance. All dust contains them, and the soil is the habitat of many forms of the greatest importance in the plan of nature. These organisms play a very important rôle in nature, and *without them vegetation, and with it animal life, would greatly diminish, if not entirely cease to exist.* . . . The microscopic fungi,or these lowest forms of plant life, are essential for the maintenance of all life." (Watson Cheyne, 1884.)

If there is any one thing demonstrable as to them, it is that they are intended to conserve the health and vitality of the higher forms of life. They reduce complex chemical substances to the simple forms in which they become available as foods. How this is done is illustrated in their relation to fermentation, and in other processes. Sometimes the work is completed by one form or species of life. In other cases these carry it only through certain stages, and other forms complete it. The laws of their growth and death; of the changes which they make in the soil, or in the host in which they grow or die; the changes which they themselves undergo, are so multifold and so minute that the student of this biology may well know that he is in a boundless museum of infinitesimal life, in which what he sees and what his enthusiasm may lead him to think he knows, has relations and modifications which, in order for absolute conclusions, almost require a minuteness of knowledge equally boundless. No wonder that we have different observations, and different inferences from observations by equally skilled observers. If is often a question as to any given microphyte, whether it is it or its secretion, or the changes it has wrought, that give trouble, and how much the soil or host is a factor in the special result.

The acquisition of specific properties by once harmless microphytes is not by any means inconceivable, and is not to be met by any off-hand analogy, such as that the egg of a goose never hatches a chicken. The attenuated and benign microphytes of Pasteur, obtained from malign ones, seem to furnish analogues to the experiments of Dr. Buchner, whom Virchow calls a good observer, and who, by various methods of culture, claims he can obtain a bacillus anthrax from a bacillus subtilis and vice versa. There is also much in the words of Dr. Sansom (1882) worth thinking about:

"I consider the differences of soil even of more importance than those of organisms in determining the nature of the specific diseases. I have long considered that there is a balance of probability in favor of the view that the specificities of disease are rather a matter of cultivation than of morphological distinctiveness."

Similar to this is the statement of Dr. Thorne, in his paper before the Epidemiological Society of London. Granting the relation of vegetable germs to specific diseases, he says:

"I know of no ground for refusing to believe that organisms capable of producing minor and incommunicable disease in particular stages of their growth, may, in other stages of their growth, or in the course of their subsequent (race) development, become capable of producing a major disease, communicable from person to person; the affair being essentially one of soil. This is *not at all a question of the development of a living organism out of matter independently of antecedent life; but merely the production by means of a process of evolution, of that which gives to an already existing organism that property by which it becomes infective.*"

We see enough of acquired habits and proclivities which change the nature, and enough of what happens to plants under varied conditions of culture, to teach us that there is wideness of range in the changes which may happen, which quite disturbs identification, and which in the yet new field of infinitesimal disease-producing botany may claim as distinct, microphytes originally of one family, and capable of reverting or of acquiring irrevertible type under certain conditions of culture or of host.

This is all the more true, since we have come to know of the marvellous history of some plant hybrids, and what great *fertility* they have.

This and much more that might be adduced in the same line of suggestion leads us to ask that the germ theory of health should now receive some consideration. If, as a working hypothesis, we start with the idea that the minute organisms were originally healthy, and helping forms of infinitesimal plant life meant to affect us only in a conservative way, we then come to inquire how they came to be changed in their qualities, and to take on specific and disease-producing qualities. Approaching the study from this direction, we seek to retrace the steps by which it became virulent, and to culture it back again to its original conservative benignity. We inquire what the host or soil it has found, has had to do with its abnormal and destructive changes, and maybe we can work on to modify the quality of soil, as well as the acquired constitution of the plant.

In such a study, perhaps, we come to find how it might be possible for cholera infantum, and for cholera, to grow into distinctness from diarrhœa; how diphtheria, derived from a series of aggravated throat distempers, should acquire a specificity of its own; how yellow fever may belong to bilious, remittent, or typhus; how typhus and typhoid were once one and the same disease; how Sydenham was not befogged when he thought scarlet fever and measles

Digitized by Google

one; how rötheln can be claimed to be a kind of hybrid. Amid the varied forms of bacilli found in the intestines of a cholera victim, it is well if we are able to select out the "comma" as the one which is pathognomonic of the disease, or which may have been a result or a cause of the disease. But it will be still better if we can get its genealogy and know the line of its development from more benign sources, or the relation and the cause of the relation which *susceptible* persons bear to its development. So we could test the view of Dr. George Harley that a fungus which may have no toxic properties when grown on one soil, may acquire toxic properties, sufficient to be deleterious to animal life, when grown in another. The very same thing has been known as to certain fish in our own waters, not as an incident, but as a uniform fact.

It seems to us high time to begin to study germs as originally fitted to aid and preserve human life, so that we may study them, not only as causes of disease, but find the lines of their departure from the norm. So we will come, not only to know what form is characteristic of a disease, but come to know whence came the change which has been wrought. So, instead of secondary causes, we may come back to the primary causes and find how much soil, host, etc., had to do with the beginnings; how much of the evil is due to the food, or to the secretions of the plant, rather than to itself. With what we now know of the laws of evolution, and how all pervading they are, we shall never rest with the idea of inherent or natural and distinct specificity as in the beginning the vicious attribute of all these countless forms of minute life.

While the physician or biologist who practises only in the laboratory may be quite sure that original specificity explains everything, there are multitudes of very observing practitioners who believe that they have had cases where diphtheria, typhoid fever, etc., arose independent of a previous case of that exact disease.

When Dr. Milligan, in 1881, received replies on this point from fifty-eight active and able practitioners of England, twenty-four replied positively that they had treated cases both of typhoid fever and diphtheria, which they believed not to have been derived from cases of the same disease. The views of Murchison as to typhoid fever are to-day the views of a large proportion of the practising physicians whose names are not so often in print as those of specialists.

The fact that a great majority of these diseases are derived from an antecedent case does not prove that all are so derived. "I have no doubt," says Niemeyer, "that in the course of centuries new infections observed have developed and taken the place of others that formerly prevailed. There is no ground for asserting that a disease is either *only* miasmatic, or *only* contagious." The failures in the doctrine of absolute specificity were ably presented in the International Medical Congress of 1881, by Professor Hueter, of Griefswald. In looking over the best authorities among active practitioners of medicine, we are struck with the number who believe in cases of fevers, of diphtheria, of whooping cough, of scarlet fever, etc., not derived from a previous case of the very same disease. All that we claim is that the finding of a form of minute plant life invariably present in a certain disease does not prove that the disease arose from that plant. It may be a "spore," a hybrid, or evolution from some harmless microphyte, a peculiar soil or condition of host having developed it into virulence, and caused it to come to have the specific type of some well-known disease, which now in *most* cases is derived from an antecedent one; and it is as important a study as to how that infinitesimal plant life got out of health, as it is to know of its action after it has become a cause or concomitant of disease. Perhaps in the thousands of generations which they accomplish in a few weeks we may culture them back to mildness, as Pasteur is doing, and in addition so establish a benign nature as to make a germ theory of health as prominent before our minds as a germ theory of disease.

YERBA SANTA AND GRINDELIA ROBUSTA IN ACUTE BRONCHITIS.

By E. STUVER, M.D.,
of Rawlins, Wyoming Ter.

About four years ago, shortly after their introduction, and while treating a number of cases of bronchitis with very indifferent success by means of the old orthodox cough mixtures, I began using the above remedies. At first I used yerba santa alone, and obtained very satisfactory results. About that time the medical journals contained numerous reports of the singularly beneficent effects exerted by grindelia robusta in asthma, and it occurred to me that it would be a valuable addition to a cough mixture, especially when designed for the relief of the very annoying cough attending bronchitis, a cough which, while the person is up and moving about during the day causes almost no inconvenience, but as soon as the recumbent position is assumed, commences with greater or less severity and continues sometimes for hours, depriving the sufferer of much needed repose, and proving a source of annoyance both to patient and physician. Accordingly, I began using the following, viz:

℞.—Fl. ext. grindeliæ robustæ,
Fl. ext. yerbæ santæ, ... āā f℥j.
Syrupi tolutanæ vel. simplicis, q. s. ad f℥iij.—M.
Sig.—℥j to ℥ij every hour or two when needed for cough.

This combination gave very satisfactory results in the great majority of cases; indeed, in some instances it acted like a charm, instantly controlling the cough and relieving the tickling in the throat and bronchial tubes.

I have now used the preparation about four years in a large number of cases, and have obtained very gratifying results. In one instance I administered it to a medical friend, who was suffering from an attack of so-called "Mountain Fever," accompanied by bronchitis and harassing cough; and so prompt was the relief afforded, and so highly pleased was he with the effect of the remedy that he has used it almost exclusively as a cough mixture in his practice since that time.

Digitized by Google

I have repeatedly used the preparation for cough and irritation of the bronchial tubes in my own case, and it always afforded prompt relief.

Many other cases might be cited with the same results, but enough has been said to indicate its field of usefulness. While I have not noticed so decided an amelioration of the cough due to chronic bronchitis or phthisis pulmonalis, as of that due to acute bronchitis, still in many cases considerable relief is obtained. I have now under treatment a lady about seventy years old, suffering from an aggravated chronic bronchitis, the symptoms of which were markedly alleviated by this preparation. Whether our high altitude (6730 feet above sea level), and light, dry atmosphere, have anything to do with the results obtained, I am unable to say; but if the preparation yields as good results in a lower altitude, and damper atmosphere as I have obtained from it here, it will confer a real benefit if used in properly selected cases.

The preparation is free from the unpleasant effects, such as headache, constipation, etc., which frequently follow the use of cough mixtures containing opiates. I have noticed no unpleasant effects following the use of small doses, but when large doses are administered temporary nausea may supervene. I have always used Parke, Davis & Co.'s fluid extracts.

HOSPITAL NOTES.

DISPENSARY FOR NERVOUS DISEASES, BALTIMORE.

Service of JOHN VAN BIBBER, M.D.

CLINICAL NOTES.

In view of the vast amount of valuable clinical material which is concentrated at the service of the Dispensary for Nervous Diseases, it is proposed to commence a series of clinical records, in which a practical account will be given of most instructive and interesting cases which come under observation. In the details of these cases I shall give the notes of my assistant, Mr. H. C. Ohle, and add to them whatever observation in regard to the progress and treatment of each case I may see fit.

The rapidly increasing literature of nervous diseases renders clinical observation especially valuable at this time. As far as is possible, importance and accuracy of detail will be in no respect neglected. But it must be remembered that many of the cases which present themselves for treatment at a clinic devoted exclusively to nervous diseases are in their origin obscure, and often ill-defined in their symptoms and progress. This class of cases may or may not be very interesting, and it will be my endeavor to select only those which are worthy of record.

It should also be remembered that the treatment of many diseases of the brain and spinal cord has heretofore been considered useless, impracticable, or merely tentative, and I look forward with great pleasure to being able to demonstrate that the efficiency of therapeutic means, in many of these conditions, has in the last few years been much enlarged and enriched. As a proof of this assertion, I have selected for the first case of this series a typical and marked one of saturnine paralysis, in which atrophy had progressed to a very decided extent in the extensor groups, and paresis was apparent in the arm and shoulder muscles. The prognosis in this case was doubtful, and after three months' treatment the result has been satisfactory and favorable in every particular. I submit the following account of the case from the notes of my assistant:

Lead Paralysis.

I. B., 38 years of age, presented himself for treatment at the dispensary March 30, 1885, suffering from paralysis of the extensor groups of muscles of both forearms.

The patient is a painter, this having been his occupation for nearly twenty-five years. He had enjoyed good health during all this time until about one year ago, when his appetite failed him, he became restless at night, lost strength, and, in his own words, "was very miserable." He stated that about six months previous to the time his health began to fail, he had little to do at his trade, and to curtail expenses he began grinding and mixing his own paints.

After this his health began to fail and his condition gradually grew worse. However, he continued at work. About the beginning of last October he noticed a slight weakness in the fingers of his right hand, followed by the same symptoms in fingers of the left hand. This weakness gradually increased, until there was complete paralysis of both forearms. This general condition grew worse and finally culminated in November in a severe attack of colic, which lasted about two weeks. He suffered severe pain during this time, and finally got relief by taking various purgatives. He has not had another attack since.

The patient had not done any work at his trade since November, being disabled by the paralysis. His general health improved again, but the paralysis grew more pronounced. He sleeps well, has a good appetite, and appears well nourished, with the exception of his arms.

On examination, I find that the extensor groups of muscles of both forearms are paralyzed and much atrophied. Temperature of extensor surface much reduced. No reaction on passing a strong faradic current. Same negative results with galvanic current.

Treatment.— Was ordered full doses of iodide of potassium, combined with ammonium carb.; and to promote circulation massage was ordered, and a stimulating liniment to rub well over the atrophied muscles, and to return daily to the institution for electrical treatment.

April 1.—Got slight reaction in affected muscles of left arm on applying faradic current, after use of galvanic current.

2d.—Got slight reaction in affected muscles of both arms on applying faradic current, after use of galvanic current.

4th.—Muscles of both arms contract more perceptibly under strong faradic current.

6th.—Applied Van Bibber's artificial extensor muscle to both arms, with instructions to wear apparatus as much as possible.

9th.—Decided improvement in both arms.

15th.—Was put on iodide of ammonium, tinct. gentian, and tinct. calumbæ.

17th.—Was put on spts. Mindererus and spts. nitric ether to promote perspiration. Noticed gradual improvement under continued use of battery.

Digitized by Google

May 14.—Patient much improved; can hold hands out straight, and strength returning. Said he wrote a note last night.

June 30.—Patient says he will not return again, as he considers himself cured; has gone to work again.

Remarks.—This case presents a very instructive feature in the rapid recovery of the muscular fibres of the extensor groups after such decided atrophy had set in. During a comparatively short treatment the recovery was remarkable, for taking into consideration the bad import of entire absence of faradic reaction, and the existence of a grave toxic atrophy, the prognosis was very unfavorable; yet the result shows what can be accomplished by faithful and persistent treatment, which was carried out actively during each day, for during the interval between the manipulations, frictions, and electricity the patient wore the elastic apparatus to prevent the strained and injurious position which is always the result of this form of paralysis.

The following case is highly interesting both in regard to the localization of brain functions and to the well-known fact of the possible mutilation of that organ without a fatal result, or without corresponding suffering or disablement. I take from the notes of my assistant the following history:

Traumatic Hemiplegia (Left).

W. Y., twenty years of age, presented himself for treatment at the dispensary, on February 20, 1885, suffering from left hemiplegia. The following history of the case was obtained: On June 30, 1884, with suicidal intent, he shot himself in right temple, about one inch superior and half inch posterior to outer angle of eye. The bullet was discharged from a twenty-two calibre pistol, held close to the part entered. He was unconscious for about twenty-four hours. On recovering consciousness, it was found that he was paralyzed on left side, both upper and lower extremities. The hemiplegia was pronounced and complete.

He was attended by the family physican and after six weeks partial motion gradually returned to the paralyzed leg, so that he was able to move around with some assistance. In this respect the case followed the usual history of hemiplegia. On examination on the day he was entered for treatment, he presented the following symptoms, viz.: Left arm totally paralyzed with slight secondary contracture. Left leg partially recovered, but has not the same strength nor same motility as in the right leg, and the muscles are not so well developed. Right eye is suffused, slight ptosis, and on ophthalmoscopic examination optic nerve is found to be atrophied. Has constant buzzing in ear of right side, which condition has been present ever since he received the wound. He presents also another curious symptom, viz., whenever he gapes, the paralyzed arm in a lazy sort of manner rises to his head, this is uncontrollable. Patient claims that he has often made an effort to keep his arm from rising, but never succeeds unless he forcibly holds it with the other hand. His health is good, sight in left eye good, hearing good in both ears notwithstanding buzzing in right ear. Appetite good, sleeps well, intellect not impaired, no pain in head.

He was put on the following treatment, viz.: Internally he was given ammon. iodide, tinct. gentian, and tinct. calumbæ. He was told to return every alternate day and have faradic current passed through the paralyzed muscles.

This treatment was continued with benefit to patient: his left leg got stronger and more developed, his left arm has improved slightly and is much stronger, although still nearly useless. The right eye was kept under observation, but as it was found that trophic changes had already commenced in the cornea, he was sent to an oculist, who after a time decided that it must be enucleated, sending the following report: "Present condition of right eye: corneitis paralytica, exfoliation beginning in the centre. Atrophy (total) of the optic nerve. Paralysis nervorum abducentis et trochlearis, and also rami recti superioris and lavatoris palp. sup. (ptosis). The operation for extirpation was successfully done about the latter part of June. The orbit was found in good condition. Patient now wears an artificial eye. He is still under treatment."

Remarks.—The group of symptoms presented by this patient makes the direction and course of his injury a most interesting problem to solve, the more so from the fact that under certain circumstances surgical interference might do much to remove or improve his paralysis. The eye symptoms, involving the optic nerve, motor oculi, and the ophthalmic branch of fifth nerve of the right eye, and a slight condition of exophthalmos in left eye, would lead us to suppose that the ball has crossed directly from point of entrance and lodged somewhere contiguous to, or pressing upon the orbit of left eye. On the other hand, the passage of the bullet in this direction could not account for his paralysis, unless it was the result of hemorrhage or the pressure of some spicula of bone detached from the inner table of the skull. This pressure might reach the ascending frontal convolution, which is superior to the point of injury, and thus cause the paralysis. It is clearly impossible that the corpus striatum of the right side could have been involved in the injury, so we must look to the cortex or motor centres to explain the hemiplegia.

Taking into consideration the nature of the injury, the close proximity of the pistol to the skull at the time of shooting, and the probable course of the ball, it has been suggested to the patient to undergo a trephining operation over or adjacent to the spot where the ball entered. This operation would be done with the hope of relieving the hemiplegia, for it would enable us to see the condition of the inner table of the skull at the point of injury, and also the appearance of the membrane at that spot.

In the next series an account will be given of this operation, which will be performed at an early day.

MEDICAL PROGRESS.

The Treatment of Cholera.—The principal physician in charge of the Cholera Hospital at Barcelona assured the *Times* correspondent that he was able to save 95 per cent. of the cases brought under treatment before the algid period, but hardly 30 per cent. after it had fully developed. Most of the patients brought to the hospital were in a very dangerous condition; and of the deaths that occurred 75 per cent. had taken place within 24 hours of the arrival of the patient. With respect to the treatment, he found that, to produce the re-

Digitized by Google

action, friction with rags steeped in ice water, followed by subcutaneous injections of ether, was most effective. To stop the diarrhœa doses of tannin and enemas of dilute perchloride of iron were useful; but most successful of all was the hypodermic administration of laudanum, which was thus retained in the system and checked the vomiting. To maintain the purity of the air, ozone was discharged in the dormitories, and all dejections instantaneously disinfected. — *Medical Times*, October 10, 1885.

The treatment which, according to *The Lancet*, has been most successful in the recent outbreak in Italy, has been large doses of laudanum given *coup sur coup* at the very first attack of diarrhœa, however slight.

THE PHYSIOLOGY OF THE INTESTINES.—PROFESSOR FUBINI AND DR. LUZZATI (*Moleschott's Utersuch.*, xiii. Bd., Heft 5), in a series of experimental contributions to the physiology of the intestines, have observed:

1. That in the small intestine of the dog there is on an average an hourly secretion of 10.6 gr. of *succus entericus*.

2. The average specific gravity of pure intestinal juice of the dog at a temperature of 24.8° F. is ordinarily 1010, and its reaction alkaline.

3. Intestinal movement, however produced, is plainly irregular and peristaltic.

4. The velocity of intestinal movement in the dog is about eleven inches per hour, the average length of the intestines being about 4.8 metres.

5. The bile in a marked degree favors the peristaltic movement of the intestine.

6. During sleep intestinal peristalsis is diminished but does not entirely cease.

7. High temperatures greatly favor intestinal peristalsis, while depression of temperature retards it.

8. The force of peristalsis in the intestine of a dog is sufficient to overcome a resistance of one hundred and twenty grains.

9. Stimulation of the right or left vagus in the neck produces no alteration in the velocity of the peristalsis of the intestine, whether produced by a weak, strong or intense induced current.

10. The mucous membrane of the intestinal tract, in which the fistula existed, during such stimulation is markedly injected.—*Lo Sperimentale*, August, 1885.

COCAINE IN THE TREATMENT OF THE OPIUM HABIT.—DRS. H. SMIDT and C. RANK report the trial of cocaine in the cure of the opium habit. In the three cases in which the remedy was used favorable results were obtained, and, without doubt, it aided in completing the cure.

In one case, by the use of the cocaine, cure, which previously had required twenty days for its accomplishment, was brought about in less than twelve days.

Maniacal exaltation was observed in one of the three cases, and was, without doubt, attributable to the drug. Concerning the efficacy of cocaine in the treatment of the opium habit, the conclusions are:

1. Cocaine, in the treatment of the opium habit, is a valuable remedy, modifying and abridging it, and while indispensable, is accompanied by no unfavorable results or sequelæ worthy of mention.

2. By the modified, slow withdrawal of the narcotic, as practised in the cases reported, decreasing doses of morphia and increasing doses of cocaine were administered.

3. Cocaine is best administered, hypodermatically, in a five per cent. aqueous solution.

4. A medium single dose, subject to increase, is five-sixths of a grain.

Doses of from one and a half grains to two grains can be administered without harm. Doses of more than three grains are dangerous.

5. So far as the present observations are concerned, the organism did not appear to become accustomed to the cocaine.—*Berliner klin. Wochenschr.*, September 14, 1885.

PERFORATING ULCER IN DIABETES.—Perforating ulcers of the foot have become associated with the protean tabes dorsalis. So far as we are aware, no observer has hitherto claimed any special association of perforating ulcer with diabetes. M. Laffon has put on record a case in which these two symptoms went together.[1] The patient was a man, aged sixty-one, who about the age of thirty-nine experienced, as the result of a shock, what he called a fever in his left foot accompanied by violent lightning pains. About a year later the big toe of the left foot became swollen, and the first and fourth toes gradually ulcerated. Later the other toes were attacked in the same fashion. Anæsthesia was present only for short distance around the ulcers. The right leg was attacked at times with painful cramps. The urine contained a large proportion of glucose. The disease of the toes was said to have some likeness to ainhum. If there were other symptoms of tabes dorsalis or of diabetes as a disease, no mention is made of them in Laffon's account.—*The Lancet*, Sept. 26, 1885.

THE TREATMENT OF CYSTALGIA IN WOMEN BY RAPID AND FORCED DILATATION OF THE URETHRA.—CHARLES MONOD, in a discussion of the treatment of cystalgia in women by rapid and forced dilatation of the urethra, classifies the various forms of the affection as:

1. Cystalgias due to lesion of the urethra (polypi and fissures).

2. Cystalgias symptomatic of a lesion of the bladder—inflammation, tumor, tubercle.

3. Cystalgias symptomatic of lesions in other organs, as those of the uterus and its annexa, or of the other pelvic viscera.

4. Cystalgias of nervous origin—*e.g.*, as symptomatic of locomotor ataxia.

5. Such manifestations of the affection as can be traced to no cause, and which may be considered as idiopathic.

The treatment of these various conditions by forced urethral dilatation is advocated—

1. In urethral affections dilatation is beneficial because exerting a beneficial influence upon the spasmodic and painful element of the disease, and also upon the lesion which has produced and maintains the cystalgia.

2. In cystalgia caused by neoplasms, dilatation, while affording temporary relief, can only be recommended as a means of diagnosis, preparatory to the ablation of the tumor.

[1] Journal de Médecine de Bordeaux, Sept. 13th.

Digitized by Google

3. In the treatment of simple cystalgia, injections of boracic acid, nitrate of silver, and sedative preparations should be tried before resorting to surgical procedure.

When urination is persistently painful and frequent, forced dilatation, which frequently gives unexpected relief, should be tried before establishing a vesico-vaginal fistula. Observation shows that this method of treatment causes pain to disappear, and also improves the condition of the vesical mucous membrane, while it also permits the easier application of local remedies. In tubercular cystitis, dilatation may be practised as a final measure for the relief of pain.

4. In conditions designated as irritable bladder, forced dilatation is especially efficacious, whether the cystalgia depends upon fissure of the cervix uteri, disease of the uterus, vagina, rectum, or anus, or is, indeed, unassociated with any recognizable lesion.—*Annales des Maladies des Organes Génito-Urinaires*, May and June, 1885.

The Treatment of Cholera.—Prof. Peter, in the course of his remarks upon the treatment of cholera, recently, asserted that the first indication is to combat the irritation of the digestive apparatus and solar plexus, for which purpose he applies a large blister to the epigastrium; in plethoric individuals he would not hesitate, he says, to put half a dozen leeches on the pit of the stomach. The pain and the cramps he endeavors to subdue by the hypodermic administration of morphia. He also advises the use of the constant current, one pole being placed on the vertebral column and the other on the epigastrium. Owing to the difficulty that is often experienced in employing electricity, he recommends the use of Chapman's spinal ice-bags as likely to fulfil the same indication, as he mentioned last year at the École de Médecine; he has tried this treatment in twelve cases, of which only two proved fatal. Indeed, he seems then to have been even more enthusiastic in its favor than now, though he has had no fresh experience to cause him to modify his opinion. Here is what he then said on the subject: "From the first application there was a notable diminution of the vomiting, of the epigastric pain, and of the cramps. The patients became warm and the pulse perceptible. This modification of the epigastric pain is interesting, for the ice-bag is far from the epigastrium, but it exerts its influence by modifying the innervation of the great splanchnic nerves. In respect to the cramps the same thing occurs. To say that ice applied to the bodies of the sufferers, already algid (almost icy cold) warms them, is a paradox, and nevertheless is not less than the truth. In fact, by putting an end to the spasm of the bloodvessels the blood is allowed to circulate, and consequently the animal heat is generated afresh. In short, ice applied along the spine and the continuous current produce similar results; but the effects of the ice are more durable than those of electricity. This superiority is due to the prolonged application of the ice, whereas the continuous current was only applied during two or three hours each day.—*Medical Times*, September 26, 1885.

The Plurality and Diversity of Neoplasms in the Same Subject and in the same Family.—M. Ricord, at the suggestion of M. Verneuil, in an investigation of this subject, has undertaken to demonstrate that contrary to the views hitherto held tumors of diverse nature may exist in the same subject—either at the same time, or periods more or less distinct. In the first and second parts of his work, M. Ricord considers benign and malignant tumors respectively, and the coexistence at the same time—on the same subject—of different forms of each variety. In the third portion of his thesis, the author discusses the coexistence of malignant and benign neoplasms in the same subject, concerning which fact he brings forward incontestable evidence.

All varieties of benign tumors seem to be able to be combined with malignant growths. The frequency of myomata places them at the head of the series, followed by sebaceous cysts, lipomata, and, finally, by fibromata and adenomata; the author further shows the combination of benign and malignant tumors in the uterus alone, and in a second series of observations collects instances of benign tumors of one organ coexisting with malignant growths in another; *e. g.*, fibroma of the uterus and cancer of the liver; lipoma of the dorsal region, and cancer of the kidney; epithelioma of the rectum, and lipoma of a limb.

A series of observations finally is given, by which the possibility of the transformation *in situ* of a benign into a malignant growth, either by operation or spontaneously, is established.

M. Ricord further holds that having demonstrated a possible multiplicity of benign, as well as of malignant, tumors, these two diatheses, apparently so distinct in character and manifestations, should be united in a single diathesis—the *neoplastic*.—*Gazette Médicale de Paris*, September 19, 1885.

The Treatment of Tapeworm.—Dr. T. Spencer Cobbold publishes, in *The Lancet* of September 26, reports of additional cases of tapeworm, bringing his series up to two hundred cases. His additional experience fully confirms all that he has previously urged in favor of male fern remedies as compared with kousso, turpentine, pomegranate root, bark, and other drugs.

Experimental Researches upon the Physiological Pathology of the Thyroid Body in the Rabbit.—Dr. Guido Tissoni gives the following results of his experiments on the pathological physiology of the thyroid body in rabbits:

1. In the rabbit the epithelial elements of the spleen take part in the physiological increase of the organ, by active indirect scission.

2. The change of these elements diminishes progressively as the organ approaches complete development.

3. In the adult rabbit, the scission changes in the epithelial cells are entirely absent or very rare, though in this animal the thyroid belongs to a group of organs whose elements have the greatest stability.

4. Reaction of the thyroid body in the rabbit to mechanical or thermic stimuli, occurs but to a slight extent, at least if estimated by the small number of epithelial cells in which changes due to the irritation are present.

5. In the rabbit, as in the dog, the complete removal of one lobe of the thyroid produces neither alteration nor hypertrophy of the other lobe.

Digitized by Google

6. The partial reproduction of this gland, though not frequent is possible, and the new formation of glandular tissue takes place perferably in the breadth, and more rarely in the length of the organ.

7. In such partial regeneration, the glandular development always occurs slowly and most frequently remains incomplete.

8. In this partial reproduction of the thyroid, it has been impossible to establish the precise method by which the glandular neo-formation is accomplished.

9. A total regeneration of the thyroid in the rabbit is possible, though verified still more rarely than the partial reproduction of the organ.

10. In total regeneration it has not been possible to determine in what parts the newly formed nodes are developed and whether they can arise from accessory thyroid organs, which on account of their diminutive size have escaped observation during operation.

11. The newly formed tissue, resulting in the partial as well as in the total reproduction of the organ, is identical histologically with that of the normal thyroid, except that in the former the glandular elements are separated by a greater quantity of connective tissue.—*Gazzetta degli Ospitali*, June 17, 1885.

OPISTHOPORIA.—This rare disease (ὀπισθε, backwards; πορεία, a going) has just been described more fully than heretofore by Dr. Mazzotti in his "Clinical and Necroscopic History of a Man who presented the phenomenon of going backwards." The man in question was sixty-six years of age, and for a year before he entered hospital was subject to giddiness. He was a hard drinker, and became so, as he said, because he "suffered from scorbutus." He got rid of his scorbutic affection, but shortly afterwards he found that instead of going forwards when he tried to walk he went backwards. On putting his feet to the ground he swayed somewhat from side to side, stretched his legs apart like one afraid of losing his balance and falling, and when exhorted to walk he moved, with great effort, stepping backwards. He was for five months in hospital, during which time he was often made to test his walking powers, but always with the result above stated. He ultimately died of ulcerous colitis, and on post-mortem examination the intracranial nerve-centres presented no other appearances than a slight degree of leptomeningitis and a highly atheromatous condition of the arteries at the base. Dr. Mazzotti's conclusion is that the phenomena presented by his patient during life were due to a simple disturbance of the endocerebral circle (*un semplice disturbo di circolo endocerebrale*), and he agrees with Nothnagel, that "to the clinical phenomenon of going backwards in walking no value can be attached as diagnostic of a localized cerebral lesion."—*The Lancet*, Sept. 26, 1885.

ANTIPYRIN.—At a late meeting of the Cambridge Medical Society, DR. MACALLISTER gave an account of the nature and uses of antipyrin, and in illustration of its valuable antipyretic properties showed the temperature charts of two patients recently treated in Addenbrooke's Hospital. Both suffered from phthisis, apparently limited to the apices of the lungs, and manifested by muco-purulent sputa, wasting, slight hæmoptysis, and the physical signs of consolidation and cavity. In one case, that of a man aged twenty-five, hectic fever made its appearance; the morning temperature was 98°, the evening 102°. Antipyrin in fifteen grain doses, administered twice in the course of the afternoon, promptly reduced the range of daily oscillation to 1°, about the normal temperature. An omission of the drug was followed by recurrence of the hectic; but again the temperature fell, and was maintained low by five grain doses given thrice a day. At the same time the patient became more comfortable and slept better; some tendency to sweating was checked by minim doses of solution of sulphate of atropia.

The other case, that of a woman aged forty-four, with still more urgent symptoms, and a temperature ranging from 98° to 103°, was treated in a similar way with equally good results. The relief and general sense of well-being produced by the medicine was a notable feature, and there was no untoward symptom. In neither patient was any rash or marked nausea produced, and both were in little more than a fortnight so much better that they were transferred to the out-patient department.

Dr. MacAllister thought that in many affections in which fever is a symptom it is sound practice to attempt to reduce the temperature for its own sake, just as we try to soothe pain when we can, irrespective for the moment of the fundamental disorder; antipyrin, of all the antipyretics he has tried, seems to be the most powerful with the fewest disadvantages. If experience justifies this conclusion, the drug may take its place beside morphia, being the allayer of fever as that is of pain.—*The Lancet*, October 10, 1885.

NEW TREATMENT OF PERIUTERINE HÆMATOCELE BY NEGATIVE GALVANO-PUNCTURE.—At the meeting of the Association Française pour l'Avancement des Sciences, held August 1, 1885, MM. APOSTOLI and DOLÉRIS presented a paper, read by the former, upon the electrical treatment of uterine hæmatocele by galvano-puncture. In an abstract of the paper forwarded to THE MEDICAL NEWS by the authors, their views are expressed as follows:

The action of the galvanic current is contemporaneously favorable with its application, the diffluent and non-retractile, soft eschar of the negative pole being utilized, and its effect being limited to the point of puncture made by the trocar. This method of puncture, therefore, primarily permits the opening without danger of a morbid collection, more or less deeply located, and places it, on the fall of the eschar, in communication with the external, which, when it occurs, forms a fistula which is more or less permanent, contracting adhesions with the pathological cavity and the exterior (the skin or mucous membrane).

This first action, which is limited and localized as desired, varies with the strength and duration of the current used. The production of an artificial fistula has the double advantage of permitting, in the first place, the natural elimination of the contents of the sac and of opening a passage of variable calibre through which topical and antiseptic treatment may be applied. It may also be added that the cicatrices left by the negative eschars are non-retractile, and only slightly visible.

Digitized by Google

In addition to the first action, which is entirely surgical, a second and medical action results, entirely dynamic and trophic, and destined to modify the nutrition of the pathological collection (abscesses, cysts, etc.), and to produce a process of retrogression more or less rapid.

The general application of the continued current is tributary to this entirely medical application: when it is intended to cure muscular hypertrophy, to abort a commencing inflammation, to resolve a ganglionic hyperplasia, to produce the regression of a fibrous tumor, or one of the connective tissue, etc. In every case, though apparently different, the idea of intervention is identical; the current, the vehicle of chemical, mechanical, and dynamic action, will advantageously influence the nervous system, which regulates all nutritive changes, accomplishing this probably by multiplying the normal electrical currents which accompany all organic movement.

Under this conception, MM. Doléris and Apostoli introduced the electrical treatment of periuterine hæmatocele, and consider that this first step in therapeutic gynecology will soon be followed by others, and that perimetritis and chronic inflammation will be found amenable to the same treatment.

The following is a summary of the method to be pursued in the application of the current:

1. *Nature of the Intervention.*—This is ordinary puncture followed by the *chemical galvano-caustic* action, which should always be *negative*.

The effects of the basic, non-retractile eschar should be utilized, which, subsequent to a variable loss of substance incident thereto, will produce a fistula which will be maintained for several days.

2. *The Location of the Puncture.*—This should be, as far as possible, in the centre of the tumor, and the loss of substance be here produced, care being taken at the same time to avoid the uterus, the intestine, or any great vessel. Combined rectal and vaginal touch will reveal the situation of the respective organs, and the arterial pulsations will render apparent the seat of any great vessel which it is necessary to avoid.

3. *The Dose of the Operation.*—This should be as great as possible, the resulting fistula and eschar being directly proportionate to it. The ability to employ 100 milliampères is necessary and easily accomplished, inasmuch as the other pole (the positive in practice) is converted into an entirely negative pole, by the employment of potter's clay, which is soft and plastic, spread upon the surface of the electrode.

4. *The Duration of the Operation.*—This, like the dose or its intensity, should be regulated according to the loss of substance and the ulterior dynamic effect it is desired to produce; from five to six minutes will generally be a sufficiently long time for its application.

5. *The Time of Operation.*—This should be as early as possible, and every uterine hæmatocele as soon as diagnosticated should be punctured without delay, which in every case renders the prognosis more serious.

6. *The Number of Operations.*—A single galvano-puncture will generally suffice to obtain the desired therapeutic effect and the production of a sufficient fistula. If, by chance, the opening close too soon and the destruction of the sac is not complete, a second application of the current is permissible.

7. *The Technique of the Operation.*—The details of the operation which should be sedulously observed are the following: Any pile which will produce a sufficiently intense current, which should be estimated by a perfect galvanometer, is suitable for the operation. The Léclanché pile is the best of medico-electrical cells. The trocar should be of moderate size, and should penetrate to a depth of from $\frac{2}{3}$ to $\frac{4}{5}$ of an inch. The indifferent pole should be a large cake of potter's clay placed upon the abdomen or thigh of the patient. The vagina should be protected by a glass or caoutchouc muff surrounding the trocar almost to its point.

8. *Steps Consecutive to the Operation.*—Strict antisepsis should be practised during the operation. The trocar should be heated preparatory and subsequent to the operation, and strong carbolic injections should be made twice daily into the sac, preceded by cleansing and sponging if possible.

9. *Complications.*—Puncture interfering with a great vessel may give rise to serious hemorrhage, which should be controlled as rapidly as possible by the immediate introduction of, and forced dilatation with, Gemrig's speculum, maintained in position for a considerable time.

The authors of this valuable paper finally conclude:

1. That in this certain and safe method of treatment of uterine hæmatocele, the ordinary gravity of prognosis is much diminished, and a more rapid cure obtained.

2. That generally the tubular cauterization of Tripier (térébration galvano-caustique) has a twofold action, surgical and medical, as before explained.

Anodyne Mixture for Dyspepsia.—M. Germain Sée recommends:

℞.—Tr. hyoscyami,
Tr. conii . . . . . āā fʒijss.
Tr. gentiani . . . . . fʒjss.
Sp. anisi . . . . . gtt. x.—M.

S. Ten to thirty drops at each meal in painful dyspepsia and in cancer of the stomach.—*L'Union Médicale*, September 24, 1885.

Treatment of Infantile Eczema.—Tirera (*Revue Thérapeutique*, October 1, 1885) recommends the following preparation for the cure of infantile eczema:

℞.—Vaselini . . . . . ʒj.
Picis liquidæ,
Hydrarg. chlor. mit. . . āā ʒss.—M.

Apply two or three times daily until cure is effected, unless the remedy becomes too irritating, when its use should be suspended for a short time. When the eruption is situated upon the head, a valuable and convenient adjuvant to the treatment is a rubber cap.

Ligature of the Subclavian Artery for Axillary Aneurism.—Mr. Bennet May records, in *The Lancet*, for October 3d, a case in which the subclavian was ligated for spontaneous axillary aneurism of eight months' duration in a man of 61. Catgut was used. The patient died on the eighth day from exhaustion, from causes unconnected with the operation. The aneurism had undergone improvement, and it was be-

Digitized by Google

lieved that the operation would have resulted in complete recovery had not death from extraneous causes ensued.

Mr. May has collected and analyzed 21 cases of axillary aneurism operated on since 1873; of these, fourteen were treated by ligature of the subclavian, of which number ten recovered, with cure of aneurism, which was of spontaneous origin, sacculated, and pulsating in all; one died of delirium tremens; one failed owing to the slipping of the catgut ligature; two failed from too free establishment of collateral circulation (both were cases of traumatic, pulseless aneurism, not suitable for ligature); amputation of the shoulder-joint was subsequently performed, with one recovery and one death. One case underwent spontaneous cure. Two cases were cured by digital pressure—both sacculated, pulsating aneurisms. One case died under galvano-puncture. Three cases were treated by the old (Syme's) operation, of which number one was cured (very small, spontaneous), one died of hemorrhage (very large, traumatic and diffuse), and one was cured (traumatic—no particulars).

The result brings out prominently the satisfactory character of treatment by ligature in appropriate cases. The previous high mortality must have been in a great degree accidental and separable from the operation; and the improvement, we may conclude, is unquestionably owing to better methods of wound treatment and materials of ligature. In fact, we may now fairly reconsider the subject from a new standpoint—viz., that of the antiseptic animal ligature—and conclude that for aneurisms of apparently spontaneous origin, which pulsate, which are encysted, or are not very widely diffused, there is no reason whatever for excluding the axillary artery from all the advantages of the Hunterian procedure.

It may be noted that compression of the artery above the clavicle has yielded good results, endorsing Mr, Holmes's recommendation that it should be the rule of practice in the first instance whenever practicable. With regard to other varieties, cases of recently ruptured artery, or of ruptured aneurism with diffusion, and with little or no pulsation, such evidence as there is in these cases is in favor of the accepted custom of treatment by the old (Syme's) method, with a reservation in favor of amputation if found impossible of completion.

EXTENSIVE CICATRICIAL STENOSIS OF THE VAGINA, DUE TO LONG RETENTION OF A FOREIGN BODY.—BREISKY (*Præger med. Wochenschr.*, 1885, No. 9) records an interesting case of cicatricial stenosis of the vagina of a young woman aged 28 years, who neither had given birth to children, nor aborted.

For seven years she had experienced severe abdominal pain during menstruation, and in the intervals between the menstrual periods an ill-smelling discharge was constant.

Examination revealed the fact that the vagina was a small blind sac. By rectal examination, a fluctuating tumor the size of an orange was discovered behind the uterus, containing a solid body having the shape of a spool. The patient now confessed what she hitherto concealed, that seven years previously she had introduced into her vagina a spool which she was unable to withdraw.

During menstruation entrance to the tumor was discovered with a filiform bougie, and without great difficulty the stricture dilated so as to permit the introduction of two fingers and the consequent removal of the foreign body, and complete recovery of the patient. —*Centralbl. für die med. Wissenschaften*, September 9, 1885.

THE COMBINED ACTION OF COCAINE AND ATROPINE IN IRITIS.—MR. WALTER H. JESSOP, in *The Lancet* for October 10th, recommends, in the treatment of iritis, the use of disks, each containing $\frac{1}{200}$ grain of cocaine hydrochlorate, and $\frac{1}{5000}$ grain of atropine.

He finds that they quickly cause great dilatation of the pupil, relief of pain, diminution of ciliary congestion, and decrease of intraocular tension when present. Now, in the active stages of iritis, as in inflammation of any other part, we have congestion of the vessels of the iris, and this gives rise to sluggishness, or even to contraction, of the pupil, followed often by posterior synechiæ. Therefore any treatment, to be successful, ought to be directed to relieving the iris of blood, and dilating the pupil as quickly as possible, so as to remove the papillary edge of the iris from the central portion of the capsule of the lens. The pain, which is such a prominent symptom of iritis, is, he believes, due either to the turgid state of the vessels, giving rise to tension of the iris, and so to pressure on its nerves, or to the tension of synechiæ. Considering the physiological action of the drugs employed, we find that atropine produces mydriasis by paralyzing the endings of the oculo-motor nerve and the unstriped muscular fibre of the iris, and, according to most observers, by stimulating also the dilating mechanism of the pupil. The action of atropine on the bloodvessels of the iris is apparently of little importance, as any constricting influence would be quickly followed by dilatation. Cocaine, as he showed in a paper before the Royal Society on June 18, 1885, acts by stimulating the ending of the mydriatic nerve of the eye, and also by constricting the small bloodvessels, thus producing a very large mydriasis, acting always to the movements of light and accommodation. Thus we see that neither drug produces alone all the effects necessary in the treatment of a case of iritis; but the combination of cocaine and atropine gives us all these—viz., an *ad maximum* dilatation of the pupil, constriction of the vessels of the iris, and inaction of the pupil to light and accommodation. The *ad maximum* dilatation of the pupil produced by this combination keeps the pupillary border of the iris away from the capsule of the lens, preventing adhesions, and also breaks down synechiæ when formed by stretching them, and by constricting their vascular supply literally starves them. From these facts doubtless ensued the excellent results of cocaine and atropine in the cases above enumerated; but Mr. Jessop would not, of course, suggest that this combination will have much effect in cases of old complete posterior synechiæ, but rather that we have in it a therapeutical remedy much more potent and certain in action in iritis than atropine. The rapid cessation of pain, which he has always seen follow the application of cocaine and atropine in iritis, enabled him to dispense with blisters and leeches in these cases.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, OCTOBER 24, 1885.

ACUTE ENDOCARDITIS.

AT the Congress of German Naturalists and Physicians recently held at Strasburg, ORTH made a valuable contribution towards the solution of certain questions concerning the nature and etiology of acute endocarditis. Klebs, and others, regard all acute inflammatory processes of the endocardium as mycotic, or due to the presence of microörganisms, but certainly, in many cases of the simple warty or verrucose endocarditis, micrococci cannot be found, nor has Orth been able, by the culture method, to demonstrate their presence. The malignant or ulcerative form, on the other hand, is characterized by the constant presence of microörganisms in the vegetations and in the secondary embolic lesions, and the problems here to be decided relate to the character of the microbes, whether one or several forms, and to the mode in which they gain access to the body.

Heretofore, experimenters have not been able to produce ulcerative endocarditis, either by the injection of various forms of bacteria into the blood, or by the laceration of the valve segments, but by a modification of the procedure Orth has been successful. Rabbits bear very well the operation of lacerating the valves by means of a sound passed into the carotid, and, as shown by Rosenbach, endocarditis does not necessarily follow. But Orth has been able to induce a typical mycotic process by injecting microörganisms into a vein of the ear shortly after the operation, and the injured valves then show an acute inflammation with penetration of the organisms into the substance and a proliferation of cells about the necrotic regions, precisely similar to the ulcerative endocarditis of man. The organisms also attack any regions of the aorta touched by the sound in passing, and induce a mycotic endarteritis. This traumatic disposition is only transitory, for if the organisms are injected even two days after the injury to the valves, no invasion of the tissues takes place; the injection, also, of too small a quantity of the bacteria was found to be ineffectual. Four different forms of microörganisms were found capable of inducing the endocarditis, but three other species, including the micrococcus of pneumonia, were inert. Differences in the intensity of the local action, and in the number and extent of the metastases, were found to exist with different forms.

In the discussion which followed, KŒSTER urged his well-known views of the embolic origin of the valve lesions, but VIRCHOW, KLEBS, and RECKLINGSHAUSEN agreed with Orth, that the superficial and non-vascular portions of the valves were usually attacked first.

These interesting experiments throw considerable light upon the disease as it occurs in man. In the first place, malignant endocarditis is a process associated, in a great majority of cases, with other diseases, such as pyæmia, pneumonia, and rheumatism, in some of which at least microbes have been discovered. In the vegetations on the valves in different cases, the organisms have not always presented the same characters, but careful cultures will alone decide this point. In one instance Orth determined the species to be the golden staphylococcus pyogenes. Secondly, the remarkable differences in the local and general effects of the different microbes in Orth's experiments, remind us of similar differences in cases of human endocarditis, in some of which there is only the local valve affection without any metastatic foci, while in others every organ of the body presents suppurating embolic lesions. And lastly, the fact that to produce mycotic endocarditis in animals requires not simply the presence of the organisms in the blood, but the existence of a local lesion, is paralleled by the very great frequency with which, in man, the process attacks sclerotic valves; indeeed, it is exceptional to find perfectly normal segments affected. The endothelium of the healthy endocardium seems able to resist the invasion of the micrococci, or, at any rate, does not offer conditions favorable to their growth; while lodging on the diseased valves they find a suitable nidus, and penetrating the tissue, induce necrosis and loss of substance.

It is a curious circumstance, that Orth was not able with the micrococcus of pneumonia to induce the disease in rabbits with lacerated valves, for on the view that the special microbe of each disease induces the complicating endocarditis, this form may be regarded as responsible for the numerous instances of severe endocarditis occurring in pneumonia.

OVARIAN HERNIA.

SIR SPENCER WELLS remarks, in his recent work upon *Abdominal Tumors*, that it is somewhat curious he has never in all his practice met with a case of hernia of the ovary. On the other hand, DR. EMERICH THOMAN has collected, in a paper published in a late number of the *Allgemeine Wiener medicinische Zeitung*, several cases of this accident, showing that it is more frequent than one would believe were he to take the experience of Sir Spencer Wells as his guide.

In Dr. Thoman's elaborate paper different varieties of hernia of the ovary are given, and examples of incarceration, of inflammation, and of cystic or malignant disease of the displaced organ are presented. Mulert, in 1867, reported two cases of primary ovarian hernia, in which the ovary alone furnished the contents of the hernial sac; he found but five similar cases reported. It thus seems that it is quite exceptional for the ovary, alone, to be found in a hernia; in most cases it has with it other organs, as the tube, the uterus, the vagina, the omentum, or a coil of intestine. It has been found that the majority of cases of ovarian hernia are congenital, and are usually associated with arrested development of the organ.

MULERT calls attention to the fact that hernia of the ovary may cause intestinal incarceration, because the entire border of the dislocated organ makes a strong band, and thus a pocket-like narrowed cavity between the uterus and the pelvic wall in which strangulation may occur; in such cases vomiting is present as in true ileus.

ENGLISCH has reported two cases of ovarian hernia, in one of which incarceration symptoms demanded herniotomy; he found both ovary and tube in the sac, to which they were strongly adherent; the sac, also, contained pus; extirpation of the ovary and tube was done, but the patient died on the thirteenth day from diffuse inflammation of the connective tissue. Englisch regards the prognosis of ovarian hernia as in most cases favorable, since strangulation rarely occurs, making herniotomy necessary.

He has added to his two cases thirty-six collected from professional literature, and of the thirty-eight thus tabulated, where the ovary alone, or the tube with it, made the contents of the hernia, twenty-seven were inguinal, nine femoral, one each through the obturator foramen, and the ischiadic. The hernia was upon both sides in nine cases, and in nine, also, the right side only, in five the left side. In most cases the disease was congenital, and in these both tube and ovary were involved in the hernia, but in the acquired cases only the ovary was included. In fifteen cases the ovary was normal, in seventeen inflamed, in five cystic, and in one cancerous. Most of the cases of inguinal hernia were congenital, while the other varieties were generally acquired.

PUECH, in 1878, collected 78 cases of ovarian hernia. Of these 47 were congenital, 12 doubtful, and 19 acquired. In later researches he collected 88 cases of inguinal hernia, 54 of which were congenital and 27 occupied both sides; he found the disorder more frequent upon the left than upon the right side. In 19 cases of herniotomy death occurred in 6.

Thoman quotes from the *Centralblatt für Gynäkologie*, No. 1, 1885, a case of incarcerated hernia in a patient two months pregnant. The woman was thirty-one years old, and was in her fourth pregnancy. Since childhood she had a tumor in the inguinal region, which at times was very painful. Urgent symptoms required an operation, and the diagnosis wavered between omental and ovarian hernia; upon opening the sac, which was the size of an egg, it was found to contain serum and the ovary, and the ovary was removed; the ovary was absent upon the other side; the patient recovered.

HEGAR and KALTENBACH state that in congenital inguinal hernia of the ovary, the latter seems firmly fixed by a rather large base to the posterior wall of the hernial sac, and it is irreducible. On the other hand, in acquired hernia, the ovary may be alone, separated from the tube, and it is generally mobile, suspended by its elongated ligament. The congenital form is often associated with other sexual anomalies, such as partial development of Müller's canals, hernia of one horn of a rudimentary uterus, or imperforate vagina.

They hold that if symptoms of incarceration, caused by inflammation of the ovary occur, it is better to remove the inflamed organ, instead of simply incising the sac. If this operation be done, great care must be taken in tying the pedicle, for this is in many cases quite short, the ligatures slip easily, and hence great liability to secondary hemorrhage. It is thought best not to let the stump enter the abdominal cavity, but to retain it in the inguinal canal.

REFORMS IN THE DISPOSAL OF REFUSE.

THE proper method of disposal of refuse matters is a question of ever-growing importance. Existing knowledge of the chief causes of diseases, as affecting masses of population, imputes to filth a most active agency in the development of influences which are hostile to life. The relation between local uncleanliness and many of the commoner ailments which afflict humanity has been so clearly shown to be one of cause and effect, that affections of such an origin are now not inaptly designated as *filth-diseases*. In order to reduce the quantity of preventable disease of this disgusting type, it is obviously the duty

Digitized by Google

of sanitary authorities to enforce cleanliness to the full extent of their responsibilities and powers. The preliminary step in this procedure is the due removal of all refuse matters and the provision for the most complete innocuousness of such matters at the place of deposit. The manner in which the fulfilment of this important service has been attempted would be an interesting subject for inquiry.

It is not our purpose to go into the details of the methods of disposal at present employed. It is sufficient to state that American cities have thus far failed to introduce any material reforms in these practices, which are as unsatisfactory as they are antiquated. The refuse of a town in an untreated state, is not considered as having any considerable commercial value, and the object of the local government has been to get rid of it in the cheapest possible manner. Schemes of utilization have failed, because attempted on a purely money-making basis. The main consideration of the immense benefits which accrue to the public health by rendering harmless these noxious matters, even though at considerable cost to the municipality, and the minor consideration of the advantages of utilization in reducing the expense of disposal, do not appear to have been rightly understood. Hence, plans of utilization entered upon with a narrow conception of the primary object, have resulted in failure. A misappreciation of the true aim of the service and a restricted economy, are chiefly to be blamed for the present faulty practices, which reflect discredit upon our cities.

The expense which a perfect system of disposal necessitates is the great obstacle in the way of its adoption. The sanitary value, which should be taken into account as a valuable asset on the credit side, seems to have been lost sight of. The least expensive plan is, as a rule, the one selected, and, as a consequence, a thoroughly efficient service is never rendered. The usual practice is to collect the garbage, dust, and ashes from habitations and the sweepings from public places, and transport them to the environs of the town; but no satisfactory disposition is made of these materials at the place of final deposit.

The local authorities seldom take the refuse removal into their own hands, but entrust this work to contractors, who are a troublesome people at best, and whose work is never so satisfactory as that done by the authorities' own servants. The uncertainty of continued employment deters them from risking the capital required for the procurement of the necessary plant. Their object being solely one of profit, they are unwilling to engage in an enterprise which requires large capital, experience, and permanency, to make it successful. Hence, the authorities are alone competent to carry out schemes which require utilization or destruction of refuse upon a comprehensive scale.

With the contract system, as generally carried out, the disposal of refuse is left almost entirely to the discretion of the contractor. Under ordinary circumstances, waste animal and vegetable matters are utilized to some extent by feeding them to swine. This practice leads to the establishment of enclosures for these animals in the environs of towns, which become the centres from which the most nauseating and unhealthful odors are distributed over entire neighborhoods. Much of the garbage finds its way into the ash-bins before removal; and this heterogeneous mixture with the street sweepings is made use of to fill in sunken places, which, in time, become the sites upon which houses are built. Disposal, by dumping into the sea, has been practised in a few instances, but, unless the point selected is distant from the land, the shores become defiled by the collection of putrescible matters. The usual disposition of excreta upon truck lands in the outskirts of a town is open to serious objection. The manner of distribution of this material is frequently the cause of a nuisance injurious to the health of the locality.

As there is no commercial value in town refuse in its crude state, except for uses which contravene sanitary law, and as these substances cannot be permitted to be cast aside to rot and poison the air and soil by their respective effluvia and soakings, the question of final disposal becomes a most serious one for solution. Their destruction or complete transformation into harmless products is the object to be sought after. Cremation has been proposed as a feasible and satisfactory method of accomplishing this object. Experiments undertaken in this direction offer great inducements to their further prosecution. The trials made at Glasgow, Edinburgh, and lately at the village of Burnley on the Thames, and in other places in England, are reported as being entirely satisfactory and the methods employed merit a test on this side of the Atlantic. By the plan adopted at the refuse despatch works at Glasgow, each day's collections, composed of the contents of ash-bins, the street sweepings, excreta, garbage, and other refuse, are transported directly to the works outside of the town. Everything which can be sold or utilized is turned to the best advantage, and the remainder reduced to inoffensive clinkers by cremation. To carry out such a scheme successfully it is necessary for the authorities to construct and manage the works themselves. In large cities it would be advisable to have a number of stations conveniently located, in order to lessen the cost of transportation.

The subject is of so much importance to the public health and comfort as to demand a close investigation of the methods already adopted with such flattering results. A change in the present practices is everywhere urgently demanded, and if relief can be had

Digitized by Google

from the nuisances for which they are responsible, the means of obtaining it should be employed without delay.

AN ALWAYS TIMELY WORD.

THE exigencies of practical teaching in our medical schools tend to hinder any marked attention to the individuality and common humanity of the patient. As a result, there is a rather wide-spread propensity on the part of students and junior practitioners, especially in hospitals, to look upon the patient in hand, not as a sentient and suffering fellow-creature, but as a more or less interesting incarnation of disease.

In the course of a recent address, PROF. OSLER made the following admirable plea for the recognition of the human element in *all* patients—a plea most opportunely addressed to an entering medical class:

"In your dealings with patients, public or private, there is but one law to regulate your conduct: 'Whatsoever ye would that men should do unto you, even so do unto them.' Kindliness of disposition and gentleness of manner are qualities essential in a practitioner. There is a tendency among young men about hospitals to study the cases, not the patients, and, in the interest which they take in the disease, to lose sight of the individual. Strive against this. Realize, so far as you can, that the mental state of the patient enters into his feelings, bear with his complaining, and scan gently his faults. The kindly word, the cheerful greeting, the sympathetic look, trivial as they may seem, help to brighten the paths of the poor sufferers, and are often as 'oil and wine' to the bruised spirits entrusted to our care."

REVIEWS.

THE TEN LAWS OF HEALTH, OR HOW DISEASES ARE PRODUCED AND PREVENTED, AND FAMILY GUIDE TO PROTECTION AGAINST EPIDEMIC DISEASES AND OTHER DANGEROUS INFECTIONS. By J. R. BLACK, M.D. 12mo. pp. 413. Baltimore, Md., 1885.

THE demand for this excellent little work has been so great that a second edition was exhausted some years since, and the present issue affords the seeker after health a revised and highly improved guide to the great *sine qua non* of all enjoyment. Dr. Black writes, in part, to obviate the complaints which are frequently made, that physicians do not endeavor to instruct their fellow-beings as they ought, in reference to the preservation of health. He offers his work with the noble purpose of contributing to the total eradication of disease, which he believes may hereafter become possible. Our author admits that man, although now more than ever monarch of the earth, is himself a poor, weak, sickly, suffering, short-lived creature; but contends that this lamentable state of human affairs is due to the fact, that for want of efforts in the right direction our race has hitherto displayed the immensity of its resources in making nature pliant to its will, but only the poverty of its resources in overcoming the causes of the numerous evils which torment its own body.

The volume is divided into two parts; the former of which comprises the ten sanitary commandments, with explanations, rules for their due observance, and detailed warnings as to the evil results of their violation. The second part is devoted to a consideration of the contagious, infectious, and pestilential diseases, with a preliminary account of the germ theory of disease, which is declared to be an accepted doctrine among physicians, the evidence in its favor being manifold and convincing. By the practical application of this theory, including the various recognized methods of destroying or shutting out the microbes of cholera, smallpox, scarlet fever, and so forth, as pointed out in the appropriate chapters, our author contends that these dreaded maladies may be prevented from spreading, in households and in neighborhoods, with great certainty.

The value of this useful volume would, in our opinion, be increased by a careful formulation of the Ten Laws of Health into definite ordinances, printed in bold type at the heads of the respective chapters, which now present somewhat the appearance of elaborate commentaries upon texts, which have themselves been inadvertently left out. Its otherwise handsome appearance is slightly marred by occasional infelicities of diction such as the following, which occurs in the preface on page 7: "The bedside of the very first cases of a deadly infection is then the only time, and the only place, to successfully arrest its spread." Still, the lessons taught by the writer, in his admirable comments upon the health laws, are rarely rendered imperfect by deficiency in clearness of expression; and notwithstanding a few verbal blemishes, the work is well calculated to accomplish a vast amount of good in the world.

SOCIETY PROCEEDINGS.

NEW YORK STATE MEDICAL ASSOCIATION.

FIFTH DISTRICT BRANCH.

First Annual Meeting, held at the Mansion House, Brooklyn, October 13, 1885.

THE PRESIDENT, JOSEPH C. HUTCHISON, M.D., IN THE CHAIR.

MORNING SESSION.

THE PRESIDENT made a brief address of welcome, in which he spoke of the prosperous condition of the Association and the good work already accomplished by it. Having appointed the nominating Committee, one from each county represented in the Fifth District Branch Association, whose duty it is to nominate the Executive Committee for the ensuing year, he called for the

REPORT OF THE EXECUTIVE COMMITTEE.

This was made by the Secretary, Dr. E. H. Squibb, of Brooklyn, and contained a number of recommendations, among which was one to the effect that a committee of three should be appointed by the Chair, to act

Digitized by Google

with similar committees from each of the District Associations at the annual meeting of the parent Association in November, in formulating a general set of by-laws for all the five branches.

Another recommendation was, that the next special meeting of the Fifth District Branch should be held in Yonkers, Westchester County, on the second Tuesday in March, 1886; and both these recommendations were afterward acted favorably upon by the meeting.

Dr. Robert Newman, of New York, then read a paper on

THE PROGRESS OF ELECTROLYSIS IN SURGERY.

Having alluded to the paper which he read at the meeting of the American Medical Association in 1883, on "Electrolysis in Surgery; and Tabular Statistics of One Hundred Cases of Urethral Stricture treated by this Method." and afterward published in two parts, one in the *Journal of the American Medical Association*, and the other in the *New England Medical Monthly*, which contained a retrospect of the work accomplished in surgical electrolysis up to May, 1883, he stated that the object of the present paper was, to relate what had been accomplished in this field during the past two years.

The only absolutely new application of electrolysis that had been made during that time, appeared to be the adoption of the method in the treatment of hernia and hemorrhoids, by Dr. Craft, of Cleveland, Ohio, a member of the American Medical Association. The radical cure of hernia by means of electrolysis is new and original, and Dr. Craft's results had never before been published; the information concerning them having been received by Dr. Newman through private correspondence. In a letter to him dated May 7, 1885, Dr. Craft wrote as follows: "I have read with much interest your article on "Electrolysis in Surgery" and its special application to urethral strictures, and I can most heartily endorse all you say in its application to strictures, having given it considerable attention. I have been using electrolysis in two difficulties that you do not speak of, namely, hernia and hemorrhoids. I have applied a positive needle electrode, properly insulated, except at the point, subcutaneously, between the external and internal rings, and allowed a sufficient galvanic current to pass between the lobes to excite quite an adhesive inflammation, being careful not to injure the cord, and to keep the needle external to the peritoneum. This results in a cicatricial healing up of the inguinal canal, and in many cases seemingly permanent."

In a subsequent letter Dr. Craft wrote that in operating the hernia should be reduced first, and the sac carried up with it, if possible. The index-finger should be invaginated in the scrotum, keeping the cord and sac, if it remain in the ring, well pressed to one side, and held there beneath the invaginated finger, which should be pushed into, or through the external ring, if possible. Then with a sharp-pointed bistoury prick through the skin over the external ring. Through this puncture push a blunt-pointed needle electrode, insulated to within a quarter of an inch of the end, carrying it well up between the rings, by the side of the invaginated finger, which holds the cord and vessels from contact with the electrode. Connect the circuit of about ten cells of a good galvanic battery, continuing the current for about six to ten minutes, according to the sensibility of the patient, changing the point of the electrode from one side of the finger to the other, always keeping as clear of the cord as possible, and directing the current from the cord. The other electrode can be held by the patient in the hand of the side operated upon, or elsewhere, as is desirable. "You ask," he continued, "why I use the positive pole, instead of the negative. For the reason that the positive is not so painful as the negative, and, being the acid pole, I conceived that it would excite sufficient irritation and inflammation, and at the same time coagulate the blood in the small vessels, thereby creating a harder cicatricial or adhesive inflammation, than the negative or alkaline pole. I think the negative pole softens tissues, and will cause absorption of already formed cicatricial tissue; but in hernia we want a hard, adhesive inflammation excited, thereby effectually healing up the rings and canal. The more inflammation excited (so that it does not injure the cord or vessels, and falls short of suppuration), the more radical will be the effect. There is no foreign matter deposited, as is the case in subcutaneous injections, to form a nucleus for suppuration. The patient should lie in bed for at least two weeks, and then use a well-fitting truss for some time, until the part becomes strong and firm."

In the spring of 1884, while living in the State of Minnesota, Dr. Craft operated upon three cases of hernia. They were all of comparatively recent date, caused by straining, in lifting heavy weights or jumping from a height, and one of the common oblique type, through the external ring, although they had not descended into the scrotum. The patients are all Norwegians, and one of them returned to his native land about three months after the operation, at which time he was well, and had done ordinary work since his recovery, without any return of the trouble. The other two patients had no return of the hernia up to the end of six months, at which time Dr. Craft left the State.

Dr. Craft thus describes his method in the treatment of hemorrhoids: "In hemorrhoids I apply the positive needle also; yet in a few cases I have applied the negative, but do not get such decided cicatrizing and shrivelling up of the pile as with the positive. I select the particular pole according to the peculiarities of each individual case. If I want to absorb the pile, I insert the negative needle; but, if I desire to seal up the vessels by adhesive inflammation, I use the positive needle."

Dr. Newman then went on to speak of the successful application of electrolysis in port-wine marks, epilation, and uterine tumors. In regard to the practicability of the method in the treatment of the latter, he said there is a great diversity of opinion in the profession, and this is, no doubt, due to the fact that some such growths are amenable to electrolysis, while others are not. A variety of circumstances also always have to be taken into consideration, such as the general state of the patient and her intercurrent diseases, as well as the great difference among operators. Whoever knows the power of electrolysis, he said, will have confidence that uterine fibroids and other tumors can be cured by it. The reports from reliable observers on this point are such that the record must be accepted as true. He then referred to over one hundred cases of positive

Digitized by Google

cure which had been reported by Drs. J. N. Freeman, of Brooklyn; J. T. Everett, of Clyde, Ohio; Ménière, of Paris; and Apostoli, of Paris. The clinical experience of the latter, extending over two years, upon more than one hundred cases, had shown that the treatment constantly reduced the size of the uterus, and completely restored the patient. In conclusion, Dr. Newman spoke of the application of electrolysis to strictures of the Eustachian tube and of the œsophagus.

DR. WILLIAM H. PANCOAST, of Philadelphia, who was present by invitation, said that he had had some experience with electrolysis in the treatment of urethral strictures, but had never been perfectly satisfied with its results. He inquired of Dr. Newman whether the positive pole really caused the absorption of tissue.

DR. NEWMAN replied that electrolysis acts in different ways, according to the method employed. Weak currents cause absorption, while strong ones destroy. His own experience had been different from that of Dr. Craft as regards the comparative painfulness of the application of the two poles. Contrary to the latter, he had found that the positive pole causes more pain, acting as an acid caustic, as it does, than the negative, which acts as an alkaline caustic. He agreed with Dr. Craft, however, as to the propriety of using the positive pole in hernia, where the object is to set up adhesive inflammation. The negative pole certainly causes absorption, and this is the one to be employed in the treatment of urethral stricture. This is the one, also, which has been so successfully used in stricture of the Eustachian tube and other strictures.

DR. ROCHESTER, of Brooklyn, was of the opinion that electrolysis is an exceedingly uncertain method of treating uterine fibroids. He had some cases which had been operated upon, and which, he was told, had been greatly relieved thereby; but he had found that the tumors are still present, and that the hemorrhage caused by them still continues, so that other measures are called for. He spoke particularly of one case of multiple fibroids, complicated by ovarian trouble, also, as he believed, which was operated on by the method of electrolysis in his presence. At the end of a week or ten days the treatment was repeated, and the operator stated that the growths were much reduced in size; but, for his own part, he could not appreciate any difference, and the same was true after a considerable number of séances. The patient, moreover, suffered great pain, and this, he thought, was probably due to localized peritonitis, induced by the application of electrolysis.

DR. GOVAN, of Stony Point, Rockland County, read the report of a

CASE OF RAILROAD ACCIDENT.

The patient was struck by a railway train, and when seen was found to be perfectly unconscious, and to have a fracture of the skull, with depression behind and above the left ear, which was caused by his head striking the ground. The patient remained unconscious for four days, and an operation for raising the depressed bone was just about to be undertaken, when it was ascertained that the bone had risen spontaneously to nearly its normal position. On the following day the depression had still further disappeared, and the patient was found to be conscious and able to speak. From this time he gradually recovered.

DR GOVAN also read the report of a

CASE OF ANILINE POISONING.

The accident was caused by the breaking of a carboy of aniline oil which the patient was engaged in removing, and he remained in a stertorous sleep for a number of hours, while there was complete anæsthesia of the entire cutaneous surface. Under the use of aconite and tonics, he gradually improved; but three days after the accident he complained of pain in the bladder, and a hemorrhage from the latter commenced which continued for two days, when it was finally checked by the use of a solution of tannic acid in tincture of uva ursi.

THE PRESIDENT asked whether Dr. Govan attributed the general anæsthesia in the last case to the effect of the oil. The anæsthetic effect of carbolic acid is well known; but it is probably not as generally known in the profession as it deserves to be, that this agent is one of the best possible applications that can be made in cases of burns. A few years ago, attention was directed to this use of carbolic acid by Dr. Squibb, and he had recently had the opportunity of testing the efficacy of the remedy in his own person. He had quite a severe burn of the finger, which destroyed the true cuticle in one part; but the pain was almost instantly relieved by dipping it in a solution of one drachm of impure carbolic acid (containing 96 per cent. of the acid) to the quart of warm water, as suggested by Dr. Squibb. He had also used it with very happy effect in the case of a little girl, in which the burns covered a very large portion of the surface of the body.

Dr. GOVAN remarked that the anæsthesia is undoubtedly due to the effect of the aniline oil, and that since he had met with this case he had used the oil very successfully for the purpose of producing local anæsthesia when laying open felons and performing other minor operations. There is absolutely no pain, even in cutting down to the bone, when the finger has first been dipped for a short time in the oil.

DR. C. S. WOOD, of New York, said that in New York at least carbolic acid had been very largely used in the treatment of burns ever since Dr. Squibb had called attention to the matter. He thought it probable that the anæsthesia in Dr. Govan's case had been caused by the oil, but that the comatose condition resulted from the inhalation of the vapor of naphtha arising from it.

DR. RUSHMORE, of Brooklyn, said that Dr. Govan's suggestion to use aniline oil when operating on felons was a most excellent one. There are other agents, such as ice and carbolic acid, which produce a sufficient amount of local anæsthesia, but the trouble with them is that their use is liable to be followed by considerable subsequent irritation.

DR. E. H. SQUIBB, of Brooklyn, remarked that the hemorrhage from the bladder in Dr. Govan's case seemed to indicate that the aniline oil was largely contaminated with carbolic acid or other byproducts of the coal-tar series, different ones of which were given off at different temperatures. It would be interesting, he thought, to note whether the peculiar effects produced in this case would result from poisoning by a specimen of perfectly pure aniline oil.

DR. PANCOAST said that generally, when local anæsthesia is resorted to, the patient suffers more or less

Digitized by Google

pain from the operation, and he was gratified to learn from Dr. Govan that when aniline oil had been used for this purpose there is absolutely no pain experienced, during the cutting of a felon, for instance. In his own practice, he said, he is in the habit of combining Bonwill's method of inducing anæsthesia by means of rapid respiration with the inhalation of a few whiffs of chloroform. Bonwill's method is not sufficient of itself, and he could not but feel that the efficacy of this procedure is largely due to its moral effect upon the patient. One great advantage of the use of general anæsthetics over local is that they not only prevent all pain, but also remove the dread of suffering, which is often an important point.

AFTERNOON SESSION.

DR. A. FLINT, of New York, read a paper entitled

SUGGESTIONS IN REGARD TO THE CAUSATION AND TREATMENT OF ACUTE CORYZA.

Having briefly referred to the causation of acute coryza by the inhalation of gases, by powders, such as ipecacuanha, which are probably largely concerned in the production of hay-fever, by iodine, and by affections like measles, he said that it was to what is ordinarily known as a cold in the head, and the incipient stage of the affection known as influenza, that he now wished to call attention. The nostrils are first affected, constituting a rhinitis, and the fault may, perhaps, go no further; but, as a rule, it progresses to other adjacent parts, with the result of producing pharyngitis, laryngitis, or bronchitis. The use of the term catarrh, which is often employed both by the profession and the laity in speaking of coryza and the other affections named, is an antiquated error which should long ago have been given up.

The word cold, so generally in use, implies a change of conditions in which the temperature of the atmosphere is necessarily concerned; but it was his aim to show that it is highly probable that coryza does not result from any agency connected with the atmosphere, but from a specific microörganism. On what grounds is such a hypothesis based? In the first place, it is demonstrable that cold has very little to do with the causation of coryza. Among those who are especially exposed to sudden successions of high and low temperature it is rare; and the same is true as regards those who are exposed continuously for a long time to cold. In a large proportion of cases the affection can not be referred to any special exposure whatever, and experience thus furnishes very little support for the ordinarily accepted view.

As is well known, coryza often operates in a more or less general manner, more than one person being affected at a time; and this seems to indicate a specific cause. This is everywhere recognized as regards influenza, and as the latter is only a more intense manifestation of the same disorder, it is logical to infer that the same holds good in regard to ordinary colds. One fact which affords support to the parasitic hypothesis is, that in a cold the various parts of the respiratory tract are affected not simultaneously, but successively; a circumstance which is satisfactorily explained by the time it takes the microörganisms to multiply into colonies after obtaining a lodgement on the mucous membrane.

These, then, are some of the rational grounds for the probable parasitic origin of acute coryza. To establish the point with certainty it is necessary to demonstrate that a specific microörganism is always present in the affection, that it is never found in any other condition, and that it can be successfully cultivated outside of the body. It is highly desirable, therefore, that some of our competent microscopists should undertake the investigation of this subject in a thoroughly scientific manner.

In regard to the treatment of acute coryza, Dr. Flint remarked that if the existence of the parasite which he had assumed be a reality, the destruction of the latter by some suitable agent will, of course, instantly cut short an attack of the affection. This will be the general rule; in exceptional cases the parasiticide will hardly be required. He stated that he had consulted four of the latest works in which the subject of coryza is treated by authors of established reputation, viz., Cohen, Ingals, Robinson, and Bosworth, and that only one of the writers referred to the probable existence of a microörganism capable of producing the irritation of the nasal mucous membrane met with in a "cold in the head." This is Cohen, and he spoke of the parasite exclusively in connection with the subject of influenza; not referring to it at all as the possible cause of ordinary coryza. All these writers, however, favorably mention the use of topical remedies, either to excite or soothe the inflamed mucous membrane, or for antiphlogistic purposes. Dr. Flint then referred to the Brandt treatment by means of carbolic acid and ammonia inhaled from a sponge; but stated that its efficacy had not been attributed to the anti-parasitic action of the remedies employed.

He did not claim any originality, he said, in calling attention to the probable parasitic origin of acute coryza. Many years ago, Dr. J. K. Mitchell, the Moses of the modern school of etiology, who was only permitted from afar to view, but not to enter into the promised land of the scientific realization of his daring conceptions, had intimated that such was the fact in regard to this and other similar affections. Later, Sir Henry Holland, of London, and Mütter, of Vienna, had also entertained similar views.

The topical treatment so generally recommended, however, while it is not ostensibly employed for its parasiticide action will, he believed, be found in reality to derive its efficiency from its energy in this direction. Thus, among the agents so used are the permanganate of potash, salicylate of soda, the vapor of turpentine, and quinine and camphor in combination. Finally, having spoken of Helmholtz's quinine treatment of hay fever, Dr. Flint said that if a parasiticide be discovered which is constantly successful in cases of acute coryza, it will offer strong rational grounds for the correctness of the doctrine suggested.

DR. WYCKOFF, of Brooklyn, remarked that in his own cases he had derived very little benefit from Helmholtz's treatment, while he found that a great deal of irritation is caused by the insufflation of the quinine solution. The theory advanced by Dr. Flint seemed, however, to be plausible, and he trusted that the matter will be thoroughly tested by a series of laboratory investigations conducted by competent observers.

DR. E. F. BRUSH, of Mount Vernon, Westchester

Digitized by Google

County, said that he remembered reading in a Virginia medical journal, he thought, a paper in which Dr. Cutter, of Boston, claimed to have discovered the true cause of influenza in a sort of polypoid, which was probably too large in size properly to come under the term bacteria. He also found that quinine killed it. This, he believed, was the first time that influenza was referred to such an origin. He is in the habit of employing ten parts of camphor to one part of quinine, and he has found that the camphor counteracts the irritating effect of the quinine. This combination often aborts an acute attack of influenza.

DR. PANCOAST said that he had made some experiments with the Helmholtz plan of treatment, and that he had been disappointed with the results obtained. He has found cubebs and camphor in combination very efficient; but the remedy which he prefers to all others is a mixture of the tincture of myrrh and borax. He asked Dr. Flint in what way the active antiphlogistic treatment, often used in colds, such as the production of free diaphoresis, etc., is efficient if the parasitic doctrine be true, and whether this efficiency can be made to tally with the latter.

DR. FLINT replied that he did not see any inconsistency in the matter. A full dose of opium, which is always part of the antiphlogistic treatment, is very efficient in breaking up a cold, just as it is very beneficial in the incipient stages of chlorea, where the parasitic origin of the disease can now be regarded as practically established. Whether the opium is directly destructive to the parasite or not, he was not prepared to say.

THE PRESIDENT remarked that the late Prof. Nathaniel Chapman, of Philadelphia, had always insisted on the special efficacy of old opium pills in acute colds, and he thought it probable that the reason why these are so useful is because in this form the effect of the opium is prolonged. In his own person he never failed to abort an attack of coryza with an old opium pill.

DR. W. MCCOLLOM, of Brooklyn, read the report of

AN OBSCURE CASE OF PULMONARY DISEASE.

The patient was a gentleman with the early history of specific disease, who had a large chest and voluminous lungs. A few months since he began to suffer from emotional excitability and from occasional paroxysms of dyspnœa. These asthmatic seizures were liable to be brought on by an unusual emotion or exercise, and as time went on they increased in frequency. A careful physical examination of the chest, however, did not detect any appreciable cardiac or pulmonary trouble. Afterward Dr. Sherwell, of Brooklyn, examined the larynx, but found no evidence whatever of any disease. He expressed the opinion that there was probably an aneurism of the arch of the aorta. Still later the patient was examined by Prof. A. Flint, who found only some subcrepitant râles on both sides of the chest. He believed that there was pulmonary œdema present, but could not say from what cause it proceeded.

In the meanwhile the dyspnœa was steadily progressive, and on the 24th of September last the patient took to bed. On the 25th he was examined by Dr. James R. Leaming, of New York, who thought that there were extensive pleuritic adhesions present, both old and new; an opinion in which he was confirmed by subsequent examinations. At this time the right lung did less work than the left, and the respiration altogether was largely abdominal.

Death occurred on the 5th of October, 1885, and an autopsy was made forty-eight hours after death.

The kidneys were entirely free from disease, and the liver, with the exception of possibly being a little fatty, was also normal. The pericardium contained two ounces of fluid, and the right ventricle of the heart was found to be moderately dilated. Otherwise the heart was perfectly healthy. The thoracic aorta was also free from disease. The lungs were of a dark gray or brown color, and were found to float in water. The parenchymatous structure of both lungs was very hard and dense, and creaked distinctly under the knife. There was no evidence of acute pneumonia, and no cavities were found. The only adhesions discovered were two slight ones at the top of the right lung, and they were evidently very old. (Specimens of the lungs were exhibited.)

DR. FLINT said that he remembered the case perfectly well, having made some notes himself upon it. He had not heard of the patient's death before, but he was very glad to know the result of the autopsy. When he made the examination of the chest in consultation with Dr. McCollom, he could discern nothing but the presence of a moist râle on both sides. He then felt quite sure that the patient had disease of the kidneys, and requested specimens of the urine. When, however, the examination of the latter gave a negative result, he felt at a loss in regard to the case, and asked to be allowed to see the patient again.

The condition of the lungs, found after death, completely explains the progressive dyspnœa, and at the same time it serves to illustrate the inadequacy of physical signs under certain circumstances. The remarkable point about this case is the equal development of the pulmonary cirrhosis on the two sides. Almost invariably the condition is much more marked in one lung than in the other; so that the difference between the two sides of the chest is very apparent. The existence of moist râles in connection with a normal condition of the heart seemed to him positively to indicate kidney disease, and he was therefore surprised to find that the urine gave no evidence of this. On the whole, therefore, he considered it a very interesting case, and the specimens that had been presented he believed were unique. He thought it also worth while, in this connection, to call attention to the mechanism of subcrepitant râles. One observer, as the history showed, had referred these râles in the present case to the presence of pleuritic adhesions. From the result of the autopsy, however, it was pretty evident that here the subcrepitant râles were produced in the smaller bronchial tubes, and not in the pleuræ.

THE PRESIDENT stated that some time since he had taken the liberty of inviting Prof. Pancoast to be present at the meeting, and that he would now call upon him to make some remarks on such topics as he might select.

DR. PANCOAST, having expressed the pleasure which it afforded him to be present on this occasion, said that he would be glad to speak on

SOME POINTS IN SURGICAL PRACTICE AND SURGICAL ANATOMY.

The first topic to which he referred was a system of

Digitized by Google

surgical treatment which had proved of great value in his hands, to which he had given the name of

The Antiphlogistic Touch of the Therapeutic Knife.

If he sees a patient early enough, this enables him to say with almost absolute certainty that there will be no abscess. Having exhibited the little knives which he is in the habit of using, he stated that the special excellence which characterizes them is, that they leave no scar. By means of one of these the part is punctured in numerous places, and the dead blood let out. The method is applicable to tumors of almost any sort, as it affords the best possible means in deep-seated bloodletting of the part. The moment a bubo, or other gathering, becomes hard and refuses to yield to the action of local applications, he freely punctures it with his little knife, and occasionally he finds that there is a drop of pus on the point. By this method he has even cured some cases of goitre, both cystic and fibroid, or at least rendered the growth so small that it gave no further trouble. He also gives internal remedies, however, such as Donovan's solution and iodide of potassium, with the addition of cinchona or whiskey, if the patient's condition seems to demand it. Many other glandular growths can also be successfully treated in the same way.

The next point was one in connection with the surgical anatomy of the face, viz.:

The Special Value of the Malar Bone,

which is often overlooked by surgeons. It is one of the hardest bones in the whole skull, and it therefore serves as a great protection; while if it can be saved, much deformity of the face is prevented. In excision of the superior maxilla, consequently, he always makes it a point to leave this bone in position; and he then proceeded to describe the operation which he had devised for this purpose. This consisted in a double-curved incision; and, after turning back the soft parts, in inserting a chain-saw through the spheno-maxillary fissure, and so cutting through the articulation of the superior maxillary with the malar bone. In this connection he related the case of a lady with a rapidly growing carcinoma of the face, upon whom he performed this operation, notwithstanding the fact that she was five months pregnant. In ten days she had recovered from the operation, and she afterwards went on to full term without any further trouble. The value of the malar bone in protecting the brain from injury was well illustrated in the case of a boy, from whose face he extracted the breech-pin of a gun which had been embedded in it, without any one's knowledge, for eleven months. The gun had exploded in his hands, knocking the boy senseless, and the breech-pin had buried itself so completely in the tissues that it was not discovered by the physician who attended him. This case taught us that under such circumstances we should always examine carefully for powder in the skin, and also make sure that some part of the gun has not been embedded in the face. Although this would seem like a very extraordinary case, it was not unique; similar ones having been reported by the late Dr. John R. Barton, and by a surgeon to one of the ophthalmic hospitals.

DR. PANCOAST next made a report of his

Treatment of Varicocele,

which he said he has now successfully practised in over four hundred cases since the year 1856. It is very simple, and, therefore, in marked contrast to that so much in vogue in New York, and advocated particularly by Dr. Henry, which involves the cutting away of a portion of the scrotum. He did not think the latter a philosophical precedure, because it simply shortens the bag in which the enlarged veins are contained, and this can be more efficiently done by suspending them in a muslin bag, because the latter is indistensible, while the shortened scrotum, consisting of elastic tissues, gradually stretches more and more, so that the trouble eventually returns. This procedure does not, therefore, go to the root of the evil. Still more complicated and serious is the operation described by Mr. Lee, in the *Lancet* of April 18, 1885, in which he cuts open the scrotum and lifts out the veins of the spermatic cord. In both these operations there is no little danger of erysipelas setting in. In his own operation the patient is cured in three or four days, instead of as many weeks. It consists of transfixing the scrotum with a sail-maker's needle (which has a good point, but no sharp edges), and passing between the vas deferens and the veins a strong silk ligature, which, having been carried around the veins, is then brought out at the point of insertion. The ends of the ligature are then tightly secured over a button of German silver or zinc, and the veins being thus strangulated, the ulcerative process goes on rapidly. In

Stricture of the Urethra

he has never yet failed to get into the bladder with the instrument which he had modelled after that of Mr. Syme. After passing the filiform bougie through the staff, the latter is pushed up to the point of stricture, which is then cut superficially at a variety of points. The urethrotome is so constructed that the knife can be made to cut as deeply or as superficially as desired. Afterwards steady and progressive dilatation is to be regularly practised, and this, he insisted, is the only method of successfully treating stricture. Dr. Pancoast also exhibited and explained the modus operandi of a very light catheter bougie, with olive-shaped extremity, which he has devised.

He next spoke of

The Advantages of Sutures of Pure Black Silk,

and he said that he always keeps a variety of sizes on hand. The white silk commonly used is colored with lead, and is apt to be poisonous to the wound, but the black silk causes no suppuration. The sutures which he uses are antiseptic, being made of pure black silk which is dyed with iron. The latter circumstance, he thought, is of service in preventing erysipelas. The silk can be rendered more antiseptic by dipping it in carbolic acid or chloride of zinc, of which he has a very high opinion. It is the strongest ligature made, and at the same time the most delicate for plastic operations. He is also in the habit of using diachylon plaster made with black silk, and finds it extremely satisfactory.

Digitized by Google

He then went on to speak of a point in surgical anatomy concerned in

Ununited Fractures of the Bones of the Leg and Forearm.

It is sometimes found that where one of the two bones in either part is broken, the fracture will not unite, notwithstanding the most skilful efforts on the part of the surgeon. The reason is, that the sound bone keeps the fragments of the broken one apart, and he has found that after fracturing this one also, there is generally no further trouble. In illustration of this point, he related a very interesting case of ununited fracture of the tibia, which was very aggravated and of very long standing, and in which the result, after he had fractured the fibula, to enable the fragments to come together, was quite remarkable.

The concluding portion of Dr. Pancoast's remarks was devoted to the consideration of *fracture of the neck of the femur in the aged* (in which he said he obtained excellent results by the use of a triple-inclined plane, the apparatus being modelled after the Charleston chair); of disease of the joints (in which he spoke of the advantages of rest); of an operation of his father's for incurvation of the penis, consisting of the removal of the V-shaped piece behind the glans, from the cavernous bodies; of the treatment of fistula in ano by the antiseptic ligature; of the subcutaneous incision of partially strangulated hernia; and of the desirability of treating chancres by the method of complete excision. He also exhibited specimens showing the results of exsections of the shoulder and of the hip, with the development of remarkable reparative processes.

On motion of Dr. Garrish, a vote of thanks was tendered Dr. Pancoast for his instructive address.

DR. J. W. S. GOULEY, of New York, discussed some of the points referred to by Dr. Pancoast. The method of punctures, for the control of inflammatory processes, he said, was a very old one. It began with acupuncture, and had been practised in various forms for the last eighty years. Thus, Velpeau used to make forty or fifty punctures sometimes in cases of orchitis. The principle is excellent; but there is nothing new about it. Having spoken of the operation of the late Dr. Charles E. Isaacs, for the removal of the superior maxilla by means of a heavy pair of forceps which he had devised, Dr. Gouley took up the subject of urethral stricture, and said that he was not in favor of multiple incisions. Only a scarification is possible, he thought, with the instrument which Dr. Pancoast had exhibited, and in his experience scarification had proved valueless. Instead of one, Dr. Pancoast left a number of cicatrices; but it was his opinion that the correct method of performing internal urethrotomy is to make one deep incision, so as to have but one cicatrix, and to make it in the floor of the urethra. This allows Nature to put in what he termed her splice of cicatricial tissue, and the operation of urethrotomy is only the beginning of the treatment of the stricture, since no stricture is cured by incision alone. This plasmatic material becomes slowly organized, and then dilatation is to be commenced. This is to be kept up not for months, but for years. As to metallic catheters, it is not once in five hundred times that he ever has any occasion to use one. If he does resort to a metallic instrument, however, he wants it very heavy, so that it will make its way into the bladder itself, and not of the light character of Dr. Pancoast's, with which he thought an inexperienced hand could do much harm. He objected to the olive-shaped extremity (which may be convenient in a soft instrument), on the ground that it is liable to make false routes, because it is three or four sizes smaller than the diameter of the shaft. Another objection to the instrument (which, however, is one that applies to a very large number of catheters) is that it has two eyes. One eye causes quite sufficient irritation, and there is no use whatever in having two. Finally, Dr. Gouley criticised Dr. Pancoast's operation for incurvation of the penis, and stated that he had performed with success an operation just the opposite of this, in which there was a longitudinal incision.

DR. GARRISH inquired whether cases of goitre were really cured by the simple method of small incisions; to which Dr. Pancoast replied that the goitre became reduced to such a size as to give no further trouble. In addition to the incisions and the internal treatment which he had mentioned, he is in the habit also of keeping up pressure by means of a rubber bandage. In reply to Dr. Gouley, he said that he did not mean to claim anything new in regard to the antiphlogistic touch, which, he was well aware, had been practised for a long time. He had, however, invented a knife by means of which the method could be employed to the best possible advantage, since it makes a suitable puncture, and nothing more. There is no incision and no scar, and the inflammation is satisfactorily relieved by it.

DR. NEWMAN said that the difference between Dr. Pancoast's method and others was, that his little knife produces no cut; and a cut, even with a sharp-pointed bistoury, will leave a scar. He had seen Dr. Pancoast use this knife in the case of delicate young ladies suffering from acne, and it left no scar or other after-effects, on account of its peculiar shape. In regard to varicocele, he had been successful in a number of cases with an appropriate truss; but it is exceedingly difficult to get an instrument maker to construct the appliance properly.

THE PRESIDENT said it was Sir Astley Cooper who first performed the operation of removing a portion of the scrotum in varicocele. Personally, he had been in the habit of resorting to the same procedure as Dr. Pancoast; but he had generally used iron wire instead of the silk ligature. It seemed to him now, however, that the latter is preferable, especially since the antiseptic properties of black silk have been shown, and in the future he will employ this. Occasionally he had known the iron wire to cause irritation, so that it had to be removed.

DR. PANCOAST then went on to reply to Dr. Gouley. In his urethrotome the knife is so arranged to cut just as deeply or superficially as the operator desires. For himself, he prefers a number of small cicatrices to one large one. He agreed with Dr. Gouley, that steady dilatation is absolutely essential for a cure, and that the cutting of the stricture is only the first stage in the process. In regard to his catheter-bougie, it is not true that the olive-shaped extremity pushes its way along the urethra. On the contrary, it has to be pushed in, and the main shaft of the instrument, which made its way along the urethra, always keeps its path in the

Digitized by Google

centre of the canal. It serves a useful purpose in preventing the mucous membrane from puckering up. In speaking of incurvation of the penis, he claimed that Dr. Gouley was wrong in his anatomy, since the corpus spongiosum belongs to the glans.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 15, 1885.

THE PRESIDENT, A. JACOBI, M.D., IN THE CHAIR.

DR. A. B. JUDSON, Secretary, reported that the

SURGICAL SECTION

of the Academy had been reorganized at a meeting held on October 12, and that it had been decided to hold the regular meetings of the Section on the second Monday of each month. Dr. Stephen Smith was elected *Chairman* of the Section, and Dr. A. B. Judson, *Secretary*. A detailed report of the first meeting was presented. The President announced that a

SECTION ON OPHTHALMOLOGY AND OTOLOGY

would be formed during the coming week.

DR. F. A. CARTH, from the Board of Trustees, reported that $2000 had recently been paid, which constituted the final payment in liquidation of the original mortgage of $10,000 on the building, so that the Academy is now entirely

FREE FROM DEBT.

DR. STEPHEN SMITH read a paper on

THE COMPARATIVE RESULTS OF OPERATIONS IN BELLEVUE HOSPITAL.

There is probably no better place, he said, in which to test the progress of practical and operative surgery than the wards of this hospital, which has within its walls and immediate environments all the conditions that in modern times are regarded as unhealthful and unsanitary. It was built between the years of 1811 and 1816, on the made lands of a cove of the East River, without drainage or adequate sewerage, and without regard to ventilation; while before its occupation as a hospital it had been used both as a prison and an almshouse. Its wards had, from time to time, been crowded with patients suffering from typhus and typhoid fevers, smallpox, puerperal fever, cholera, and yellow fever, and although many changes had been made in its interior, yet the great and most serious defects of location and construction had remained unaltered, and might be regarded as permanent.

Bellevue can be regarded as a surgical hospital only since 1850, and during that period the amount of surgery in its wards has been gradually increasing. The surgeons of this institution have always ranked among the best in the city, and yet the practice of surgery has, within the period mentioned, undergone so complete a revolution that one of the older surgeons would scarcely realize that he was in the same hospital where he had practised a decade ago.

He would see with horror, said Dr. Smith, operations fearlessly performed that he had formerly regarded as without the pale of legitimate surgery. He would witness procedures in the after-treatment of operations which would seem to him to be fantastic, and even ludicrous. His astonishment would be extreme on finding that the first week passed without fever, and that no change in the dressing had been made. But, perhaps the most remarkable feature of modern practice would be the rapid convalescence and final complete recovery, without complication or exhaustion, of ordinary operations, which formerly gave so much trouble and anxiety.

To make more evident the change in practice, Dr. Smith proceeded to contrast in detail the several steps of operations in general, and of individual cases, the methods of treatment, and the results. Having mentioned that before the use of anæsthetics the most important general principle governing the operator was celerity, in order to limit as much as possible the amount of pain, he said that now one thought and purpose occupied the mind of the surgeon, and that is, recovery without suppuration. Instruments are not only protected from rust and all soiling and kept sharp, but long before the operation they are plâced in a carbolic solution, in order that any possible septic matter on them, or their handles, will be destroyed; and during the operation one assistant devotes himself entirely to the duty of handing the instruments to the operator, and of receiving them from him, and at once submerging them in the disinfectant fluid.

He first took up the performance of operations, such as amputations, for instance, describing the methods by which absolute cleanliness is now secured, in contrast to the former practice, when in the simple failure to secure ordinary cleanliness of the surface wounds were more frequently poisoned and induced to suppurate than from any other cause. In speaking of ligatures he said: Recognizing the silk ligature as an irritant, the surgeon always used to cut off but one end, and left the other depending from the wound, to be removed by traction when it had finally separated from the end of the vessel to which it had been applied. And well and faithfully did the ligature meet its indications, for during the first week, the most critical period in the history of the wound, it did not fail to induce free, and often profuse, suppuration. But now, not only does the surgeon freely apply the ligature, but he cuts off both ends, and closes the wound as completely as if there was no foreign substance left between its surfaces. No suppuration follows the presence of the ligatures, and union takes place as promptly as if no ligatures had been used.

Having referred to the past and present methods of closing wounds and of after-treatment, Dr. Smith went on to say that if we followed the wounds treated by these two methods from the first to the last dressings, the contrast was remarkable. If the wound was large, fever formerly began on the second or third day, announcing suppuration, and from this date, for weeks after, the dressings were changed daily, one, two, or three times. The pus-basin, the irrigator, and the dressing forceps were in constant demand, and in many wounds the suppuration was so profuse that vessels were placed under them which received the continuous discharge. The fever generally ran high, with consequent exhaustion and depression of the patient. Septicæmia, as now understood, was the intermediary fever of that day, and was regarded as a usual, if not a necessary, sequel of

Digitized by Google

all considerable operations. Following this fever, or rather insidiously engrafted upon it, were chills, fever and profuse sweatings, now recognized as pyæmia, but then regarded as only another step of surgical fever. Few indeed survived this fever; and in the diffused or metastatic abscesses revealed at the autopsy the surgeon discovered a cause of death quite beyond his power to prevent, control, or even comprehend.

The vast change in the progress of operated cases during the past ten years could scarcely be realized. Surgical fever, with all its disastrous variations, is, in practice, rare now in Bellevue Hospital. Pus, as an outcome of surgical operations, is a thing of the past. On one occasion, Dr. Smith said, a teacher in one of the medical colleges sent to the wards of Bellevue for a specimen of pus for exhibition to his class; but none was found in the four surgical divisions of the hospital, although there was at that time an unusually large number of wounds and operated cases under active treatment. The wound is now dressed with no expectation that fever will arise, that suppuration will occur, or that the dressings will require renewal on account of the presence of pus. The patient sleeps and eats well from the first, and the surgeon often removes the dressing only to find the wound united; a condition of affairs which is true not only of incised wounds but equally of wounds of amputations, excision, ligature of arteries, etc.

Turning from this review of the several stages of operations in general to particular operations, he said that many curious illustrations of the remarkable progress of practical surgery in this hospital are to be found; in proof of which he cited the treatment of compound fractures, in which amputation is now never thought of unless arteries and nerves are so far destroyed that death of the extremity must follow amputations, excision of the larger joints, and ligation of large arteries. In speaking of amputations, he said that an interne once made the statement that "a recovery after amputation of thigh had not occurred in Bellevue Hospital since the time that the memory of man runneth not to the contrary," a remark which, although not strictly true, had a painful significance to the surgeons of that period.

If the major operations are now performed with so much success, Dr. Smith went on to say, it follows that the minor ones are correspondingly successful; a good instance of which is afforded in the improvement in the treatment of cold abscesses. Perhaps the most marked illustration of the great improvement in operating surgery, however, is to be found in the unvarying success which attends the treatment of simple fracture of the patella, by wiring together the fragments; a procedure which embodies the very spirit and genius of the surgery of to-day, viz.: Boldness and audacity in the conception of an operation, and conservatism the most absolute in the methods and means employed in executing it. This operation is now accepted as legitimate, and no procedure, so inherently dangerous when performed according to old methods, has ever proved more successful.

After briefly referring to the success attending gynecological operations in this hospital, Dr. Smith concluded in the following language: In reviewing the surgical practice at Bellevue, it is not difficult to determine the essential feature of the present methods as compared with those of the past. Cleanliness is the one great object sought to be obtained in all operations. Whatever may be the final conclusions of scientific students as to the cause of putrefaction of wounds, practically, it is determined that the surgeon may, with the most absolute certainty, protect an ordinary open wound from suppuration. To effect this object, he finds that he has simply to resort to those measures which are known to secure perfect cleanliness of the wound. The agents now relied upon and found efficient are: 1. Soap and water to external parts. 2. Carbolic solutions for the instruments. 3. Bichloride solutions to all surfaces and tissues. 4. Iodoform for external dressings. We may summarize the conditions regarded as essential to success as follows, viz.: A clean operator, clean assistants, a clean patient, clean instruments, and clean dressings.

DR. ALFRED C. POST said that he could cordially endorse the sentiments expressed by Dr. Smith, more especially in regard to the matter of thorough cleanliness. He thought there is still some room for question as to how far antiseptics, so-called, contribute to the admirable results which are now obtained in surgical practice. The great point he believed to be, perfect cleanliness, and the seclusion of the wound from malign influences from without. His doubt as to the value of antiseptics had its orgin in the reported experience of the renowned gynecological surgeons of Great Britain, such as Lawson Tait and Dr. Thomas Keith, who had discarded their use. They trust entirely to thorough cleanliness and had even expressed the opinion that antiseptics add slightly to the mortality of such operations as they are accustomed to perform. It is to be noticed, however, that these surgeons are always careful to have their sponges and ligatures treated with antiseptic solutions beforehand. Still, they do not cleanse their hands with antiseptics, and apply no antiseptic dressing after their operations. Personally, Dr. Post said, he is somewhat disposed to believe in the efficacy of antiseptics, but at the same time he felt a little staggered by the extraordinary success of the surgeons referred to, without them. The success of Spencer Wells, who still employs antiseptics, is not as great as that of Lawson Tait and Dr. Keith. But, at all events, whatever the name, the fact remains that the improvement in surgical practice has been very marked.

DR. W. GILL WYLIE stated that until three or four years ago ovariotomy was not performed at all in Bellevue Hospital, on account of the extreme mortality attending the operation there. When he was an interne in the hospital, in 1870, Listerism was just beginning to find its way there. It has, at all events, taught us the lesson of perfect cleanliness; and he thought it somewhat doubtful whether we should ever have learned this lesson had it not been for the labors of Mr. Lister. He differed from Dr. Post in believing that antiseptics are themselves beneficial, although their employment may have been carried to excess. It must not be forgotten that every one who employs coverings of cotton-wool, which is one of the best agents that we possess for protecting parts from deleterious influences, is, in fact, using a Lister dressing. Tait and Keith, on account of the extraordinary cleanliness which they practise, may not require antiseptics; but should their hands become contaminated in performing operations, or autopsies, he thought that they would not hesi-

Digitized by Google

tate to use them on their own persons, as occasion demanded. For himself, he made use of antiseptics simply as a supplementary measure; and if he was certain that he could secure absolute cleanliness without their assistance he would not employ them either. But all surgeons engaged in active practice are liable to contamination, and therefore he thought is much safer not to dispense with antiseptics. Tait's recent statements in regard to these agents are simply an expression of the present reaction against them, and he thought they are likely to do much mischief in rendering surgeons careless, so that they will not adopt those measures of extreme cleanliness which are essential to the highest success in practice.

Dr. Wylie said, in conclusion, that when he came out of Bellvue, after his service as an interne in its wards, he was of the opinion that the whole place ought to be pulled down; but now, although there is certainly much to be desired about the arrangements of the building, he is convinced that, with the methods at present in vogue, the most excellent results can be obtained there. It is a great injustice to Lister to cry down antiseptics, as we never knew what cleanliness was until he taught us.

DR. F. V. WHITE said he would like to inquire of Dr. Smith whether he was accustomed to get bony or ligamentous union in treating fractures of the patella with the method and under the favorable circumstances which he had described.

DR. WESLEY M. CARPENTER remarked that the various points of Dr. Smith's paper had passed before his mind like a very pleasant panorama. He had begun to frequent the wards and dead-house of Bellevue about twelve years ago, and was perfectly familiar with the history so graphically related this evening. What struck him particularly, in looking back over three years, was the absence at the present day from the dead-house of the hospital of those grave internal lesions, such as surgical kidney, which used to be so common in those dying in the surgical wards. There was certainly a remarkable and most gratifying change in this respect, and, so far as he was able to recollect, he had not seen a case of surgical kidney there for five or six years. Such pathological conditions are now virtually a thing of the past. Again, in former times autopsies in cases in which death resulted from surgical operations were very frequent; but this is no longer the case, and all these happy results have, as all know, followed upon the adoption of what is known as antiseptic surgery.

DR. SMITH, in closing the discussion, remarked that he did not intend in his paper to discuss antiseptics or any theories respecting them. It is his own impression, however, that the improvement in surgical practice which he had described are due simply to the securing of extreme cleanliness. In the first place, the condition of the surgeon, the assistants, the nurses, the instruments, etc., is carefully looked after. Especially is attention paid to the nails, which were formerly one of the most frequent sources of contamination. In the second place, the parts are always washed until they are thoroughly clean; and not only the parts in the immediate vicinity of the wound or operation, but, in fact, the entire person of the patient. The share that can be claimed for mere antiseptics in the good results noted is probably very slight; but, at the same time, they serve a most excellent purpose in stimulating us to the carrying out of these measures of perfect cleanliness. Those, therefore, who are now ridiculing antiseptics he believed to be doing great mischief. Mr. Tait had made the statement that carbolic acid never comes near his patients; but he had met with a patient of that surgeon's who had informed him that in his actual practice he does not discard antiseptics so completely as he would have us believe, and that the minutest care is always observed in regard to his ligatures, sponges, instruments, etc. If, however, the present cry be kept up against antiseptics, great carelessness is sure to ensue, especially on the part of those who have always been opposed to their use, and, in consequence, very bad results will once more be seen in surgical practice.

In reply to Dr. White's question, Dr. Smith said that he did not know whether bony union is secured in fracture of the patella or not. The results are very satisfactory, however, and so he thought that there must be either bony union, or else extremely firm fibrous union.

A TRIENNIAL PRIZE IN MEMORY OF THE LATE DR. ERNST KRACKOWIZER.

THE SECRETARY read the following communication:

NEW YORK, October 14, 1885.

To the Academy of Medicine.

12 West Thirty-first Street, New York:

At a meeting of physicians and laymen, friends of the late Dr. Ernst Krackowizer, who died September 23, 1875, held October 13, 1885, the following preamble and resolutions were unanimously adopted:

Whereas, During his long activity in New York City, Dr. Ernst Krackowizer rendered eminent services to both the city and the medical profession; and,

Whereas, It is both desirable and proper to preserve the memory of this great man in the history of the city and the medical profession; and,

Whereas, Dr. Ernst Krackowizer was, during all his professional life, a zealous and self-sacrificing Fellow of the New York Academy of Medicine, which never had a more enlightened, learned, and generous friend than he; therefore be it

Resolved, That the sum of eleven hundred and fifty-five dollars be transferred to the New York Academy of Medicine, upon the following conditions:

First. That the accumulated interest of the above sum be utilized, every three years, as a prize for a good, or the best, paper, essay, or book, on a medical topic.

Second. That the above sum be forever registered and carried on the returns of the property of the New York Academy of Medicine as the "Ernst Krackowizer Prize Fund;" and,

Third. That at the proper times the prize questions, essays, or books, and rewards, be published in the principal medical journals of the United States.

Resolved, Further, that it shall be left to the wisdom of the Council of the Academy of Medicine to determine whether the prize is to be awarded as a recognition of either the best literary medical production of America during the previous three years, or of the most satisfactory solution of a question or problem proposed for competition.

Digitized by Google

Resolved, Finally, that the President and Corresponding Secretary of the New York Academy of Medicine, and the Presidents of the College of Physicians and Surgeons, the University Medical College, and the Bellevue Hospital Medical College, officiating at the time of the several awards, shall constitute the Prize Committee, unless the Academy of Medicine, or its Council, decide differently.

On motion, the gift was accepted, and the matter referred to the Council of the Academy with power.

CHICAGO GYNECOLOGICAL SOCIETY.

Stated Meeting, September 18, 1885.

THE PRESIDENT, H. P. MERRIMAN, M.D., IN THE CHAIR.

DR. E. C. DUDLEY made some informal remarks relative to his observations in

GYNECOLOGICAL AND ABDOMINAL SURGERY IN EUROPE

during a summer holiday. His observations were confined to the work of a few operators in England, Scotland, and Heidelberg.

In Heidelberg, he called upon Professor Kehrer, and inspected the hospital and saw evidence of considerable work in abdominal surgery. Professor Kehrer's laboratory gave evidence of active research into gynecological bacteriology. His work bore the stamp of thoroughness and efficiency.

Dr. Dudley saw Dr. Bantock operate at the Samaritan Hospital London. The first operation was the removal of a small, solid ovarian tumor. The remaining ovary and tube, although normal, were removed on account of a small intramural, uterine fibroid. The striking feature of the operation was great rapidity without haste. Dr. Bantock caught up the edges of the peritoneum with small compression forceps, so that these edges were drawn up toward the cutaneous edges, and were held in this position by the weight of the instrument against the abdominal surface. This manœuvre greatly facilitated the passage of the sutures. The pedicle was secured by means of silk ligatures, applied in the operator's peculiar figure-of-eight turns. In closing the wound, a needle of ovoid shape, curved on the edge, instead of on the flat, was employed. This needle combines the maximum of strength with the minimum of size. Two or three sutures were passed through at each angle of the wound. Their ends were joined by knots. An assistant, passing the index-finger of each hand through the loops thus formed, made traction at each angle of the wound, in such a manner as to draw its sides into contact, and to lift the peritoneal edges nearer to the surface. The introduction of the remaining sutures was in this manner greatly facilitated. The sutures were so closely passed that no superficial stitches were required. They were made to include a very narrow margin of skin and peritoneum, and very little if any muscular tissue. Fine silkworm gut was employed.

The ends of the sutures, on each side of the wound, were now grasped in lock forceps, which prevented them from being drawn out, or becoming tangled during the separation of the wound from the toilet of the peritoneum, which was most thorough, the entire cavity being rendered perfectly clean and dry. The lock forceps were then removed from the ends of the sutures, and the hands of the assistant substituted. Traction was then made on all the sutures, in the direction of the upper angle of the wound. and they were tied in order from below upward and cut short. This prevents tangling of the threads and otherwise facilitates tying. Antiseptics, throughout the operation, were conspicuous by their absence. The dressings were of the most simple character.

Dr. Dudley then visited Birmingham, and saw Mr. Lawson Tait operate.

His rapid method of operating conveys to the casual observer the idea of haste and almost of carelessness. But closer observation very soon shows him to be one of those rare operators in whom dexterity amounts almost to a sleight of hand. An ovariotomy, in his hands, does not impress the observer as a capital operation. It seems almost as trivial as opening an abscess. His methods of operating do not materially differ from those of Dr. Bantock. In closing the wound he used but one needle, threaded with a piece of long silk, introducing this as if for a continuous suture, but did not draw the thread tight. After the introduction of the needle, he left a long loop before the reintroduction. Then, after taking the last stitch, he lifted the free loops of silk on the index-finger, and severed them with the scissors, thereby converting the continuous into an interrupted suture. These were tied in the ordinary way, and the wound was dressed in a manner which would be eminently acceptable to his most bitter antiseptic enemy.

During a brief visit in Edinburgh, Dr. Dudley saw Dr. Skene Keith perform his forty-eighth ovariotomy. Up to this time, he had lost only one or two patients. His operation presented some interesting peculiarities. He used probe-pointed scissors of a peculiar pattern, instead of the director, in going down through the deeper layers of the abdominal walls. By pressing firmly against the adhesions with a sponge, at the point of their attachment to the cyst, he literally sponged them away from the tumor. It was surprising to note the facility with which rather firm adhesions were thus broken. It is much easier to tear them from the tumor with the sponge than to tear the tumor from the adhesions. The breaking of the adhesions in this way is also much more gentle, and, in the opinion of Dr. Keith, diminishes the danger of shock. The adhesions were ligatured with fine catgut as fast as they were divided. In passing the ligatures a forceps, similar to the ordinary compression forceps, was used. This instrument had blades more than an inch long, of very small diameter, terminating in sharp points, so sharp that when the blades were closed they could be thrust through any soft tissue like a large needle. Grasping the ligature in the point of these blades, the tissue to be ligatured was transfixed. The ligature was then pulled through and the forceps withdrawn. The pedicle was transfixed and ligatured, with fine silk, in the same way.

The cautery, to which much of the elder Keith's success has been attributed, was not employed in this case, because the pedicle was very slender. The reason why the cautery, in the hands of other operators, has not proved a more perfect protection against hemorrhage, becomes apparent to any one who has witnessed its ap-

Digitized by Google

plication in the hands of Dr. Keith. The whole secret of his method is, first, in the powerful compression of the pedicle between the broad blades of a heavy Baker-Brown clamp; second in the prolonged application of the red-hot cautery iron, not only to the pedicle, but, after this has been burned to the level of the clamp, also to the clamp itself. In this way the clamp becomes so hot that the included portion of the pedicle is slowly and thoroughly cooked, so that when the instrument is removed the end of the pedicle is thin and translucent, resembling a horny substance. Such a pedicle, in the experience of Dr. Keith, never gives trouble from oozing.

The wound was closed with fine silk sutures which had been boiled. Ten or fifteen pieces of silk were threaded at each end with very fine, well-tempered needles nearly three inches long, which were introduced on either side from within outward. Very small margins of peritoneum and skin were included in the sutures. Dr. Keith thought it a very common fault among operators to draw the stitches too tight in tying. The long fine needle used in closing the wound is superior. It makes a very small puncture, which never bleeds, and is so fine that it is easily pushed through by means of finger and thumb without needle forceps.

The wonderful success without antiseptics recorded by the great Scotch ovariotomist, Dr. Bantock, and by Mr. Tait, who have reduced the mortality to a very low degree, must have great influence in fixing the value of Listerism so far as it relates to abdominal surgery. At any rate, incompetent operators can no longer venture with impunity upon these capital operations under the dangerous impression, that in some mysterious way antiseptics will deprive a crude surgical performance of its greatest perils. Evidently it was not so much a question of Listerism as of removing the tumor with the least possible amount of operating, and in the shortest time consistent with careful attention to detail, and in the most gentle manner.

Dr. Dudley, however, raised the pertinent question whether Listerism should be placed on trial before a court of abdominal surgeons, and whether, if found unnecessary in peritoneal surgery, it would be fair to condemn it in general. He thought that such a verdict can not be sustained by the facts, but that the antiseptic principle in surgery is destined to stand. Even the most violent opponents of antiseptics agree that perfect cleanliness is essential. He knew of no other method by which cleanliness can be rendered so nearly absolute. Nor does the seeming ability of two or three of the most dextrous operators to do without antiseptics prove that it is not a useful aid to others. Clearly, the man who removes a tumor with the least operating and handling of the parts will require fewer preventive measures against inflammation and sepsis. Antiseptics, therefore, are most valuable for an inexperienced operator, and, to say the least, an additional safeguard for any one.

Some American operators are now having about as good results as can be shown in Great Britain, which seem to indicate that our former high mortality in this American operation has been due in reality to bad operating, and not, as many supposed, to climatic causes.

Prof. Christian Fenger replied to the question, raised by Dr. Dudley, that antiseptic precautions may be more important in surgery, in general, than in abdominal surgery, where it looks as though more perfect methods of operating without antisepsis give as good results as with antisepsis, as follows:

He thought that the abdominal, or rather peritoneal cavity, in respect to the antiseptic precautions, occupies a peculiar position in surgery. The danger from absorption of the poisonous antiseptics is far greater in the abdomen than in wounds. The ability of the peritoneum to absorb serous fluid and blood before it decomposes, to encapsulate foreign substances not capable of absorption—*ex. gr.*, rubber ligature—is perhaps somewhat greater than the ability of a wound in that direction, although it may be that there is some prejudice about this, as we have not as yet used silk ligatures extensively in general surgery.

As to the question, whether more perfect methods of operating without antisepsis will improve the results, or rather prevent inflammation and sepsis, he could say that outside of the peritoneum this question must as yet be answered in the negative.

In 1873, Volkman, of Halle, introduced the Lister method of dressing and operating in his surgical clinics. In his report of the work done in 1873 (*Beiträge zur Chirurgie*, 1875), antiseptic surgery had reduced inflammatory and septic complications following excisions, amputations, fresh penetrating articular wounds, fresh open fractures, to a minimum never before dreamt of, and all this in one year. In the broad field of surgery it is not possible that Volkmann or anybody else could improve the *technique* of operating, to the extent of having the results change all of a sudden in that way. No surgeon would dare, to-day, to excise, for example, a knee-joint, without antiseptic precautions in all the minute details, even if he employed all the latest improvements in the method of operating. Abdominal surgery is the only branch of surgery in which, as yet, the heavy operating has been done without antiseptic precautions.

CORRESPONDENCE.

CHOLECYSTOTOMY.

To the Editor of The Medical News.

Sir: In your issue of August 22d you quote from a paper by M. Thiriar, in which it is stated that "the operation proposed by Mr. Lawson Tait is attended by the inconvenience of leaving a biliary fistula, a condition not free from danger."

I do not know who M. Thiriar is, but it is inconceivable how he has managed to make such a misstatement. The operation leaves a biliary fistula just so long as lithotomy leaves a urinary fistula—that is, until the wound heals, and this generally occurs in twenty days unless some stone, undiscovered at the time of operation, has been left. If this has happened, the non-closure of the wound speedily proves it, the stone is removed and the wound heals. This is what I have published more than once, and this is my uniform experience, but M. Thiriar would make it appear that the fistula is a permanent result of the operation.

I am, etc.,

Lawson Tait.

Birmingham, October 2, 1885.

MEDICINE IN CHINA.

To the Editor of THE MEDICAL NEWS.

SIR: In reading your article of to-day under this caption, I was disappointed in not finding some reference to the Chinese treatment of syphilis, a disease which, I am credibly informed, they are very skilful in curing.

Parties who have contracted this disease on the Pacific slope where the Chinese element is numerous, have told me that, after undergoing a protracted mercurial course and subsequently the mixed treatment, only to find that the disease had not entirely yielded, they were advised to consult a Chinese physician, who cured them in a week or two. My informants were not able to tell what medicinal agents were used in accomplishing this result, only that they consisted entirely of herbs. Little bits of branches or twigs were deftly arranged together, about the length of an ordinary candle. The patient was advised to light one end of this and go to bed, and allow it to burn, to the extent of about one-third of its length, under the blanket which is covered over the patient's head. He was enjoined to breathe the smoke resulting from this, and he said that it nearly killed him. It caused the most profuse diaphoresis, intense dyspnœa, and utter prostration. This procedure was repeated three or four times, and from that day to this, a period of fourteen years, no symptoms of the disease have manifested themselves in the case to which I refer. I am not sure but that some herbs were given in an infusion, for the patient to drink in conjunction with the inhalation process.

Judging from the character and habits of the Chinese in California, and from the great prevalence of the disease amongst them there, I am led to suppose that syphilis is widespread in China. If this be the case, it is quite probable that the ingenious Chinese mind has evolved some mode of treatment of this disease which has not come to our knowledge. If this be the case, let us have all the information procurable on the subject, no matter if obtained from the "Heathen Chinee."

Yours respectfully,
H. J. MURPHY, M.D.

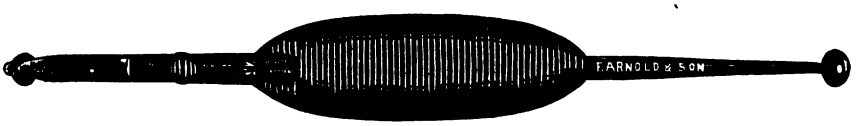
CHATHAM, ONTARIO, October 17, 1885.

NEW INVENTIONS.

A NEW COMEDO EXTRACTOR.[1]

BY ROBERT B. MORISON, M.D.,
OF BALTIMORE.

THE extractor consists of a handle of steel, which has two arms extending from it. At the end of each arm is a small steel cup, with highly polished outside surface, the bottom of which is pierced by a small hole. The cups are bent at an angle of 45 degrees. On one arm there is a small knife, made like a dagger, which, by being pushed, runs through the cup, in which there is a slit cut to receive it. It projects beyond the outside surface of the cup about the eighth of an inch, and is guided by a slot which works upon a pin upon the arm of the instrument, and is removable for sharpening and cleansing.



The advantages of the instrument over others of its kind are the slight indentation made by the cup upon the skin; the chance it gives one of watching the comedo as it is extracted, thereby regulating the necessary pressure; the possibility of using a knife and pressure at the same time without changing instruments, and the difference in size of the holes in each cup.

The accompanying figure, of normal size, shows the instrument without further explanation.

It was made for me by Arnold & Son, of 15 Hopkins Place, Baltimore, to whom my thanks are due for elaboration of details.

[1] Exhibited at the ninth annual meeting of the American Dermatological Association, August, 1885.

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

POISONED BEER.—The zeal displayed by one Bureau of the Health Department, that which deals with food adulterations, etc., has more than once been expressed in a way to excite ridicule. A recent sensational paragraph in the *Herald*, headed "Poisoned Beer," details the discoveries of Dr. Cyrus Edson and his coadjutors of metallic impregnation from contact with the pipes. Yet it furthermore declares that, owing to the excess of organic matter, no copper or other salts could be found. To those who daily use Fehling's test, this new scientific truth will be a novelty.

SMALLPOX.—Notwithstanding the terrible ravages of smallpox in Montreal, there has been very little of the disease here. The admirable system of limiting vaccination, instituted during the outbreak of 1873 by the New York Board, has been rigorously adhered to, and our safety is due to this.

MENTHOL has been extensively used in this city as a remedy for hay fever, and with some success.

WASHINGTON.

(*From our Special Correspondent.*)

PRECAUTIONS AGAINST THE INTRODUCTION OF SMALLPOX.—Inspection stations have been established by the Marine-Hospital Service at the towns lying on the Canadian border of the States of Maine, Vermont, and New York. The States of New Hampshire and Michigan are maintaining their own inspection stations at present, the State of Michigan having an appropriation which became available on the 18th of September for this purpose, thus relieving the Government from the further conduct of the work and continuance of the inspection service in that State. The New Hampshire inspectors are working in harmony with those under the Marine-Hospital Service in Vermont. The inspec-

Digitized by Google

tions are having a twofold effect. They not only prevent the introduction into the United States of unvaccinated persons, but have had a reflex influence in stimulating the Montreal authorities to renewed efforts, which, owing to recent decisions of the local courts, they are now fully empowered to carry into effect. Surgeon H. W. Austin, under the direction of the Surgeon-General of the Marine-Hospital Service, has had charge of the organization of the inspection service along the border, from Moose River, Maine, to Buffalo, N. Y.

MORE RESIGNATIONS FROM THE CONGRESS.—DR. HENRY I. BOWDITCH, of Boston, declines the Vice-Presidency of the proposed Congress in the following open letter, which is published in *The Boston Medical and Surgical Journal:*

"Since Dr. J. S. Billings, as Secretary of the Committee for arranging the International Congress for 1887, informed me that I was selected as one of the vice-presidents of the Congress, I have had no *official* notice either of my summary displacement by the new committee at its meeting in Chicago (June 24) or of my reinstatement by the same committee (Sept. 3). For this and other reasons to be named, I ask a place in your Journal for the following statement: When urged by some friends to sign the protest made in several cities, by gentlemen opposed to the action taken at New Orleans, I replied, 'It would be absurd for me to do so, because the Committee has already expelled me from office.'

"Since that time I have watched with interest the course pursued by *The Journal of the American Medical Association*, and also that of the new committe for the International Congress. I have read with pain the perpetually recurring bitterness and insinuations against all those who had dared to express opinions adverse to the doings of the Association, or those of its new committee. I was surprised and disgusted while reading the editorials of August 1st, entitled 'The International Medical Congress and its Enemies,' and that of August 29th, 'International Medical Congress of 1887 and the American Medical Association.' From these editorials any foreigner reading them would not have the least suspicion that the controversy on the 'Code' had any share in the embroglio, at present existing. I wholly deny that those who now disapprove of the course the Association and its Committee have taken, are the 'enemies of the International Congress.' On the contrary, they are, in my opinion, its best friends.

"Notwithstanding my objection to such editorials, I have continued to decline to sign the protest in the hope that, by so acting, I might perchance do something toward the promotion of professional harmony in America.

"But the last manifesto of the Committee and gross assumption of despotic power for making all future arrangements for the Congress (*vide* 'Executive Committee of the Ninth International Congress,' *Journal American Medical Association*, September 3d) convince me that I can remain no longer in the position to which the new committee (as I learn from the journals) placed me without my knowledge or consent at their meeting in September."

Dr. George W. Major, of Montreal, has declined to serve on the Council of the Section of Laryngology.

REGULATIONS FOR THE MAINTENANCE OF QUARANTINE INSPECTIONS ON THE NORTHERN FRONTIER OF THE UNITED STATES.—Dr. John B. Hamilton, Supervising Surgeon-General U. S. Marine-Hospital Service, has issued the following circular:

The act approved April 29, 1878, entitled "An act to prevent the introduction of contagious or infectious diseases into the United States," provides that no vessel or vehicle coming from any foreign port or country where any contagious or infectious disease exists, or any vessel or vehicle conveying persons, merchandise, or animals affected with any contagious disease, shall enter any port of the United States, or pass the boundary line between the United States and any foreign country, except in such manner as may be prescribed under said act.

Attention is now directed to the prevalence of the contagious and infectious disease of smallpox in Montreal and other places in the Dominion of Canada, and the law referred to is held to apply alike to trains of cars and other vehicles crossing the border, and to vessels entering ports on the northern frontier.

Because, therefore, of the danger which attaches to the transportation of persons and baggage, and articles of merchandise, or animals, from the infected districts, the following regulations are framed, under the direction of the Secretary of the Treasury, and subject to the approval of the President, for the protection of the health of the people of the United States against the danger referred to:

1. Until further orders, all vessels arriving from ports in Canada and trains of cars and other vehicles crossing the border-line, must be examined by a medical inspector of the Marine-Hospital Service before they will be allowed to enter the United States, unless provision shall have been made by State or municipal quarantine laws and regulations for such examination.

2. All persons arriving from Canada by rail or otherwise must be examined by such medical inspector before they will be allowed to enter the United States, unless provision has been made for such examination as aforesaid.

3. All persons coming from infected districts, not giving satisfactory evidence of protection against smallpox, will be prohibited from proceeding into the United States until after such period as the medical inspector, the local quarantine, or other sanitary officer duly authorized, may direct.

4. The inspectors will vaccinate all unprotected persons who desire, or are willing to submit to, vaccination free of charge. Any such person refusing to be vaccinated shall be prevented from entering the United States.

5. All baggage, clothing, and other effects, and articles of merchandise, coming from infected districts, and liable to carry infection, or suspected of being infected, will be subjected to thorough disinfection.

6. All persons showing evidence of having had smallpox or varioloid. or who exhibit a well-defined mark of recent vaccination, may be considered protected, but the wearing-apparel and baggage of such protected persons who may come from infected districts, or have

Digitized by Google

been exposed to infection, will be subjected to thorough disinfection as above provided.

7. Customs officers and U. S. medical inspectors will consult and act in conjunction with authorized State and local health authorities so far as may be practicable, and unnecessary detention of trains or other vehicles, persons, animals, baggage, or merchandise, will be avoided so far as may be consistent with the prevention of the introduction of diseases dangerous to the public health into the United States.

8. Inspectors will make full weekly reports of services performed under this regulation.

9. As provided in Section 5 of said act, all quarantine officers or agents acting under any State or municipal system, upon the application of the respective State or municipal authorities, are empowered to enforce the provisions of these regulations, and are hereby authorized to prevent the entrance into the United States of any vessel or vehicle, person, merchandise, or animals prohibited under the act aforesaid.

10. In the enforcement of these regulations there shall be no interference with any quarantine laws or regulations existing under or to be provided for by any State or municipal authority.

THE PROFESSORSHIP OF PHARMACOLOGY AT THE JOHNS HOPKINS UNIVERSITY.—It is rumored that Prof. Matthew Hay, of Aberdeen, Scotland, has been offered and will accept this position, and will enter upon its duties next autumn.

THE WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—At the annual meeting of the Washington Obstetrical and Gynecological Society, held on October 16, 1885, the following officers were elected for the ensuing year:

President.—Dr. A. F. A. King.

Vice-Presidents.—Drs. W. W. Johnston and J. Taber Johnson.

Recording Secretary.—Dr. C. H. A. Kleinschmidt.

Corresponding Secretary.—Dr. S. S. Adams.

Treasurer.—Dr. G. B. Harrison.

THE DEATH OF PROF. ROBIN.—The founder and for a long time the leader, of the French school of histology, Professor Charles Robin, died on Tuesday last of apoplexy, at the age of 64.

The history of Professor Robin was for a long space of time the history of medical microscopy itself, and he stood prominent as the representative of that branch of study, in opposition to Velpeau and other practical and clinical teachers, who endeavored to cast ridicule upon the microscope and histology as viewed in relation to medical science. The triumph of Robin appeared complete, when, in 1861, a chair of histology was created at the Faculty of Medicine, of which he became, of course, the first occupant. His success was great at first, but he soon became unpopular with the students on account of his extreme severity as an examiner; while on the other hand, the clerical party, then predominant, were incensed at the so-called materialistic tendencies of his lectures and writings. The combination of these two hostile forces led to violent scenes, in which the Professor was hissed, abused, and prevented from speaking. At a later period he regained his popularity through the petty persecutions of the clerical party, which, among other annoyances, excluded him from the list of persons qualified to sit upon a jury, although at this time Robin was unquestionably one of the most celebrated men of science in Europe. He had become, in spite of strenuous opposition, a member of the Institute in 1866. When the Senate was created, in 1870, Robin was named a Senator by his native department (Ain). He remained a member of the Assembly till his death, although in politics, like many scientific and literary celebrities, he was content to play a dumb part. Indeed, both his qualities and defects made him unfit to play the part of a Demosthenes; he had neither the eloquence nor the assurance which are the stamps of the political orator, and which are seldom developed by a severe process of scientific training.

Robin was one of the chief disciples of Auguste Comte, and one of the founders of the celebrated *Société de Biologie*, along with his intimate friend Claude Bernard. He was also closely connected with Littré, and became with him one of the joint editors of the *Dictionnaire de Nysten*, which, although in the beginning a mere vocabulary of words employed in medical science, became a stumbling-block to orthodox believers, and a sort of gospel to the followers of positivism, through the extreme boldness of some of its definitions, those for instance, of *Ame*, *Homme*, and a few others of the same description. In private life Robin was a most amiable and disinterested man. All his pupils were much attached to him, and he will be sincerely regretted by his numerous friends.

The Chair of Histology at the Faculty of Medicine, left vacant by Robin's death, will probably be disputed by numerous candidates, among whom the most prominent are Drs. Lancereaux and Mathias Duval and Professor Ranvier.—*Medical Times*, October 10, 1885.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM OCTOBER 13 TO OCTOBER 19, 1885.

VOLLUM, E. P., *Lieutenant-Colonel and Surgeon.*—Assigned to duty as Attending Surgeon, Headquarters Department of the Platte, Omaha, Nebraska, relieving Assistant Surgeon Wm. C. Shannon.—*S. O. 103, Department of the Platte*, October 15, 1885.

IRWIN, B. J. D., *Lieutenant-Colonel and Assistant Medical Purveyor.*—Ordered from Department of Arizona to New York City, for temporary duty in charge of Medical Purveying Depot at that place, relieving Captain Henry Johnson, Medical Storekeeper.—*S. O. 233, A. G. O.*, October 10, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING OCTOBER 17, 1885.

BALDWIN, L. B., *Passed Assistant Surgeon.*—Detached from Naval Hospital, Philadelphia, and ordered to Navy Yard, Mare Island.

DICKINSON, D., *Surgeon.*—Detached from Naval Hospital, Mare Island, and ordered to Training Ship "Portsmouth," as relief to Surgeon A. M. Moore.

MOORE, A. M., *Surgeon.*—Detached from Training Ship "Portsmouth," and wait orders.

SHAFER, JOSEPH, *Assistant Surgeon.*—Detached from Receiving Ship "St. Louis," and ordered to Naval Hospital, Philadelphia, as relief of Past Assistant Surgeon Baldwin.

HESTER, F. A., *Assistant Surgeon.*—Detached from United States Steamer "Minnesota" and ordered to the "Tennessee," as relief of Passed Assistant Surgeon Nelson H. Drake.

DRAKE, NELSON H., *Passed Assistant Surgeon.*—Detached from the "Tennessee," 31st instant, and wait orders.

REMARKS ON THE TREATMENT OF ROSE-COLD AND HAY FEVER BY COCAINE.[1]

BY J. M. DA COSTA, M.D.,

PROFESSOR OF, MEDICINE IN THE JEFFERSON MEDICAL COLLEGE.

IN a communication which I made to the Colleg last December,[2] I suggested that cocaine ought to b advantageous in hay fever. During the past summe I have had several opportunities of carrying thi thought into effect, and, as I see by some very recen journals, others, too, have employed the drug wit the same purpose; altogether, I think, it has bee sufficiently tested for us to welcome it as a very de cided addition to our means of counteracting thi most troublesome affection.

The first case in which I became familiar with it use was one of great susceptibility of the nasal mucou membrane, which I saw last spring in a Souther gentleman. It was more like rose-cold, strictl speaking, than like hay fever, but due to the sam irritability of the mucous membrane, and alway marked and most annoying with early vegetatior A two per cent. solution, which I afterward increase for a time to a four per cent. solution, gave him suc comfort and relief, that I had some difficulty in ir ducing him to discontinue the remedy. He said tha its local employ not only soothed the intolerabl irritation and stopped the sneezing fits, but exerte a quieting influence over his whole nervous systen similar to what he experienced from small doses c morphia, to the influence of which he was very ser sitive.

One of the most striking instances of success I ha with cocaine was in a young lady who had been fc four years a great sufferer with rose-cold, whic always came on about the middle of May, and laste until June. Later it became a hay fever, and at tacks of troublesome asthma complicated the dis order during the summer and the early autumn especially in the latter part of July and August. Sh is a young lady with a sound digestion, and calr nervous system. It has been her habit to leave he country home in summer to go to Newport, whenc generally, after a month's struggle with asthma, sh has been obliged to move to some of the hay feve resorts in the White Mountains. Her eyes and nos suffer much in the earlier stages of the complaint there is, however, no sore throat. Later a bronchia affection and asthma appear. The main complair in the earlier stages is from the intolerable sneezing This occurs especially in paroxysms in the morning and is apt to stop after breakfast, although on cool day

[1] Read before the College of Physicians of Philadelphia, Oct ber 7, 1885.

[2] Published in THE MEDICAL NEWS of December 13, 1884.

Digitized by Google

a varying susceptibility—to cocaine locally used. Thus, in an elderly lady with rose-cold, in whom no local remedies act speedily, a four per cent. solution produced very little impression. I meant to try an eight per cent. solution, but, as she left the city, I had no chance, and am thus forced to record this case as a failure.

The manner of employing the cocaine is not without importance. It may be used with a small atomizer as a spray. But the readiest means is to inject from five to eight drops up each nostril, the head being thrown backwards; in some persons once, in most, twice daily, will be found sufficient. It will be necessary to instruct patients not to irritate the membrane by rubbing it needlessly with the glass tube, or pushing this up too far. Thus a patient who had hay fever for thirteen years, and who was at the seashore on the 17th of August when the hay fever came on, and in whom tincture of ignatia amara seemed favorably to influence its course, tried cocaine in one nostril only. He inserted the tube far up, irritated the membrane, and water ran from that nostril, which became sorer and more inflamed than the other. More judicious attempts produced better results, but he could not be persuaded to give the remedy a fair trial, owing to his first experience with it.

Its mode of action in hay fever is partly by the local insensibility it produces, partly by the contractions of the capillaries it induces. The effects are thus chiefly local. It will not arrest the bronchial catarrh or the asthma, which attend some cases; yet it is astonishing how it seems to lessen the tendency to these complications when early applied, and before they have got much headway. Is its action, then, not partly a reflex action? That the remedy is radical, and, strictly speaking, curative, I have not found; but that it gives great comfort, converts bad into light cases, enables those to stay at their homes who otherwise are obliged to flee to hay fever resorts, relieves much suffering and distress, I know and have fairly tested. In no case of rose-cold or hay fever ought cocaine to be left untried.

CONTRIBUTION TO THE ETIOLOGY OF MALIGNANT TUMORS.

BY R. J. HALL, M.D.,
OF NEW YORK.

So much of an almost purely speculative character has been written during the last few years on the etiology of malignant tumors, that did this paper contain merely a new hypothesis, I should scarcely venture to present it to the Surgical Society.

It consists, however, chiefly of a series of cases, most of which have come under my own observation, which, in my judgment, strongly support that hypothesis which is slowly but surely working its way into the minds of most thinking pathologists and surgeons. I refer to the hypothesis which attributes these mysterious neoplasms to a specific virus, in all probability a microörganism.

Without stopping to give an accurate definition of the term "tumor" in general, it may be sufficient to say that by malignant tumors we mean such as invade the neighboring tissues and produce metastases,[1] and that all such tumors are included in two great classes, carcinoma and sarcoma. In regard to the first of these, almost all pathologists have accepted Waldeyer's view, that the cells which occupy the alveoli are epithelial, and the tumors, therefore, are essentially of epithelial origin; while there is no doubt whatever that the sarcomata are built up of connective-tissue elements.

The theories hitherto formulated in regard to the origin of these tumors have been so well classified by Dr. H. F. Formad, in an exhaustive paper on the same subject, that I cannot do better than reproduce this classification. Under each heading he has given a list of the pathologists who have supported the hypothesis. This list is as follows:

1. Predisposition and inflammation theory (Virchow, S. D. Gross, Woodward, Samuel Wagner, Birch-Hirschfeld, Cornil and Ranvier, Perls, Tyson, Gross).[2]

2. Dyscrasia theory (Rokitansky, Paget, Billroth, Simon).

3. Embryonal theory (Cohnheim, Thiersch, Waldeyer, Lücke, Masse, Hasse, Epstein).

4. Idiopathic or spontaneous (Rindfleisch, Stricker, Nancrede, Payne).

5. Nervous theory (Van der Kolk, Lang, Snow).

The nervous theory is, I think I may safely say, too fanciful to merit discussion, except when considered as a possible predisposing cause. The idiopathic and dyscrasic theories mean nothing, the terms themselves being mere words which either confess our ignorance or serve as a cloak to hide it. Cohnheim's, or the embryonal, theory, which has lately fallen into some discredit, undoubtedly offers a satisfactory explanation of the origin of some benign tumors, and may afford a beautiful explanation of one of the facts in regard to the structure of many malignant tumors apparently most difficult to reconcile with our hypothesis. For, if in certain regions, as in the parotid, embryonic remains are of frequent or constant occurrence, and in others occur rarely or not at all, we can understand why in the one case the same irritant should give us a mixed, in the other a simple tumor.

There remains then only the predisposition and inflammation theory. Under the great authority of Virchow pathologists have been ready enough to accept this last as a sufficient explanation; that they have been and are still very slow to recognize that inflammation is of a specific kind, is due, I think, chiefly to the following causes. When following closely on his cellular pathology, it was demonstrated by Virchow that tumors consisted of cells not differing genetically from those found in normal tissues, the discovery excited such enthusiasm that many were convinced that the life history of the cell alone could sufficiently account for all the phenomena. Thus, according to the widely accepted view of Thiersch, in old age the resistance of the connective tissue is diminished, the interstitial spaces are widened under some local irritation, the deeper epithelial layers proliferate and penetrate the underlying tissues, penetrate the lymph spaces, and are swept into the neighboring lymphatic glands where, in accordance with

Digitized by Google

their life history, they develop indefinitely, and not being on a surface where constant desquamation can occur, must do so at the expense of the surrounding tissues. Thiersch, while correctly recognizing the inflammatory character of at least one group of malignant tumors, the carcinomata, could not at that time make the distinction now clearly recognized between simple, or non-infective, inflammations, and infective, and his followers, with less excuse, refuse to do so even now. We have many instances of local infective inflammations giving rise to metastases; not one, so far as I know, of the non-infective. The view that malignant tumors are of inflammatory origin is one which has spread widely among pathologists, especially since it has been found necessary to place the so-called granulomata, tubercle, lepra, and syphilis among the inflammatory diseases. The points of analogy between these and the malignant tumors are too numerous and obvious to have escaped observation. They have been presented at length by Dr. Formad in an exhaustive paper,[3] and by Dr. Nedopil.[4] Time will only permit me to discuss them briefly to-night.

Tubercle, which may be taken as the representative of the granulomata, was long considered to be an ordinary inflammation in a tissue predisposed to disease. This is the standpoint which many pathologists occupy at present in regard to malignant disease. It is interesting to note that Formad,[5] whose weakness for peculiarities in the lymphatic system as sufficient to account for the origin of tubercle led him to reject the tubercle bacillus, and brought down on him what can only be described as the annihilating criticisms of Professor Koch[6] and Dr. Shakespeare,[6] finds in the absence of the endothelium of the lymph spaces, in carcinomata and sarcomata, a sufficient explanation of their peculiar growth.

Numerous attempts have been made to show that the anatomical peculiarities of tubercle tissue, epithelioid cells, giant cells, cheesy degeneration, are sufficient to account for all the peculiarities of the disease. The researches of Baumgarten[8] and Weigert[9] show that they represent only the reaction of the enfeebled cells under the irritation caused by the bacillus. A pathologist can hardly fail to be struck by the similarity of the enormously hypertrophied cells almost constantly found in sarcomata and carcinomata to the epithelioid and giant cells of tubercle, while the frequency with which they are found in a state of fatty degeneration, and the readiness with which they undergo spontaneous necrosis remind us forcibly of cheesy degeneration. The discussion was not yet quite terminated among pathologists as to whether tubercle tissue always differs so much from other inflammatory products as to make the microscopic diagnosis possible in every case. In the same way the exact line between certain sarcomata and the products of chronic inflammation has never yet been drawn, while that form of tubercular skin disease known as lupus papillaris or verrucosis, commonest on the dorsum of the hand, and of undoubted inflammatory origin, is, as I have myself had occasion to observe, undistinguishable under the microscope from epithelioma.[10] Into what absurdities we may be led by regarding carcinoma as merely a non-specific inflammatory process is well shown by the statement of Formad,[11] that there are great numbers of chronic ulcers of the leg in the Philadelphia hospital, and that a large proportion of them are carcinomata—because he has found epithelial nests and proliferation of the interpapillary epithelium.

Both tuberculosis, as seen by the surgeon, and malignant tumors are distinctly associated with traumatisms. Thus Volkmann states that the great majority of tubercular bone and joint diseases are referable to an injury,[12] while Formad alleges that he finds an inflammatory origin in nearly one-half of all tumors.

Dr. D. G. Zesas quotes[13] S. Wolff's statistics drawn from tumor cases observed in the surgical clinic at Berlin between 1864 and 1873, according to which in 344 cases of carcinomata a trauma was given as the cause forty-two times, and in 100 of sarcoma twenty times.

It is well known that sarcomata usually follow a single injury, and carcinomata a long-continued irritation. The reverse, however, is by no means unknown. Thus Weil[14] gives two cases of sarcoma attributed to repeated irritation. Dr. R. F. Weir[15] has reported a case of scirrhus of the penis following a contusion received four months previously, and refers to a similar case reported by Holmes Coote.[16] J. W. Spulke* reports a case, occurrring in a man aged 68, in which a small wound of the palate, made by the stem of a pipe driven into the mouth, was followed in a month by a small wart, which grew rapidly, and six months after extirpation recurred, extended rapidly and caused the death of the patient. Microscopic examination proved the tumor to be an epithelioma.

If we deny the existence of a specific virus in these cases, we are compelled to fall back upon the vague term predisposition, which was formerly used to explain the cases of tubercular disease having a similar origin. On the hypothesis of a non-specific inflammatory origin, it is difficult to account for the fact that in some countries malignant tumors are practically unknown.[17] For surely contusions and chronic inflammatory processes with diminished resisting power on the part of the connective tissue cannot be wholly wanting in these places. One of the strongest objections made to the assumption of a specific poison in the case of malignant diseases, has been the absence of any evidence of contagion. Cohnheim[18] denied the existence of a specific poison on the ground that the surgeon is never infected from his patient, *or the husband from the wife.* It is well to remember that precisely the same objection was made to the tubercle bacillus. Many physicians of large experience declared that they had never seen a case of even probable tubercular infection; yet now the journals are filled with them, and while the surgeon seems still to be safe, the anatomist has not been spared.[18]

It is to meet this objection that I have ventured to present the following cases to the Surgical Society. Three of the series are from the practice of Dr. Sands, and one or both of the patients concerned in each case have come under my own observation; for the fourth I am indebted to Dr. Markoe, and the fifth

Digitized by Google

was seen at the Outdoor Department of the Roosevelt Hospital by myself:

CASE I.—Mr. Thomas E. C., æt. 40, married, N. Y., clerk, admitted to Roosevelt Hospital December 3, 1878. Family history good. Patient has varicocele on the left side, and tumor of the left testicle of twenty-two months growth, the size of a cocoanut, smooth, firm, and of fibrous consistency. Extirpation of the tumor January 3, 1879, by Dr. Sands. Death January 26 from suppression of urine due to pressure on the ureters by metastatic growths in abdominal cavity. Microscopic examination by Dr. Delafield showed the tumor of testicle and in the abdominal cavity to be encephaloid carcinoma[19].

Mr. C.'s widow subsequently married. Margaret Anne, N. Y. City, æt. 50 years and 3 months, died while under my care, April 12, 1885, with carcinoma "en cuirasse," originating in the mammæ. Tumors were stated to have been first noticed in 1882, and in both breasts at the same time. The growth was confined to the mammary glands and the skin, no enlargement of the axillary glands occurred, and only superficial ulceration of the carcinoma. Death due to repeated hemorrhages from the ulcerating surface and to exhaustion. No autopsy obtained.

Mrs. L.'s mother, Mary Anne D., died January 20, 1885, æt. 81 years and 6 months, of acute bronchitis and broncho-pneumonia. One month before her death the patient consulted me with regard to a rapidly growing tumor of the right breast, which she had first noticed one month previously. My diagnosis was probable carcinoma. The tumor was seen also by Dr. Sands, who concurred with me. The family history of this patient was good, especially no history of tumors. She had been a good deal with her daughter during the illness of the latter, but did not live in the same house. No autopsy obtained.

CASE II.—Mrs. D., æt. 43, with good family history, was subjected to operation by Dr. Sands on May 5, 1882, for carcinoma of the right breast of one year's duration. Recurrence took place about six months later, and the patient died about April, 1883. Microscopical examination by Dr. Satterthwaite showed tumor to be scirrhous carcinoma. Mr. George D., æt. 47, husband of the last patient, came under observation October 20, 1882, suffering from tumor of the superior maxilla. A younger brother died five years ago of what was said to be recurrent sarcoma of the testicle. Family history otherwise good. About three months ago the patient noticed a swelling in the left superior maxillary region, and thinks he noticed a hard lump beneath the left angle of the lower jaw some time before this. Both tumors have grown rapidly since. A tumor of soft consistency occupies the situation of the left superior maxilla, and extends in the direction of the malar bone. There is a mass of enlarged glands beneath the left angle of the lower jaw. Extirpation of the tumor and enlarged glands by Dr. Sands. Rapid recurrence and death in May, 1883. Microscopic examination shows the tumor to be an epithelioma.

CASE III.—Miss Isabella S., admitted to Roosevelt Hospital May 25, 1885, suffering from a rapidly growing tumor involving the right superior maxilla, and said to be of three months' duration. Extirpation of the superior maxilla by Dr. Sands, May 27, 1885. Death from shock and hemorrhage following the operation. Microscopic examination shows the tumor to be a giant-celled sarcoma. Mr. F. J. G., æt. 20, single, was engaged to Miss S. for some months before her death. He was submitted to a surgical operation on September 9, 1885, by Dr. Post for the removal of a small cystic tumor of the right superior maxilla, said to be of only three weeks' duration. The tumor lay in front of the antrum and did not occupy its cavity. Microscopic examination shows the tumor to be a giant-celled sarcoma.

CASE IV.—Taken from Dr. Markoe's work on *Diseases of Bones*, p. 266, 1882. Mrs. S. N. E., æt. about 23, consulted Dr. Markoe March 26, 1866, for a small tumor occupying the right side of the neck, behind the sterno-mastoid, and about the size of a hickory-nut. Operation May 1, 1866, when tumor was found closely attached to the transverse process of the fourth cervical vertebra. Recurrence after a few months, and slow growth until April 10, 1869, when a second operation was performed. Recurrence in fall of 1869, with gradually increasing paralysis due to pressure on spinal cord. Third operation on January 25, 1871, followed by complete relief of all the symptoms and no recurrence up to the present time. Microscopic examination by Dr. Delafield showed the tumor to be a myxo-sarcoma.

Mr. E., æt. 56, husband of the last patient, underwent on January 19, 1885, an exploratory incision of the abdomen, to determine the nature of an abdominal tumor, the symptoms of which dated from December, 1884. A soft friable tumor was found matting the viscera together in such a way as to prevent the possibility of its removal. The tumor was considered by Dr. Markoe to be sarcoma, probably originating in the great omentum. The patient died about three days after the operation. No autopsy was obtained.

CASE V.—Thomas C., N. Y., æt. 53, September 4, 1885; family and personal history good, especially no history of tumors or syphilis. Sixteen years ago the patient broke his left arm near the elbow, but recovered without stiffness or deformity. One month ago the left elbow and the right ankle became swollen, and swelling has increased rapidly since, without pain, redness, or tenderness, except over the internal malleolus where the pain is quite severe. Examination shows that the inferior extremities of the left humerus and the right tibia are expanded, so as to form distinct tumors, being smooth and of bony hardness. The neighboring bones and articulations are unaffected. Diagnosis of simultaneous sarcoma of the humerus and tibia. The patient was examined by a number of surgeons, who all concurred in the diagnosis. The tumors were especially unlike, in their growth and character, syphilitic or tubercular deposits, which almost alone might be supposed to come into consideration.

While taking the patient's history, I accidentally elicited the fact that his wife had died last February, after a six weeks' illness, with rapidly advancing hemiplegia of the left side, and that the diagnosis of the attending physician, Dr. A. R. Robinson, of this

Digitized by Google

city, was tumor of the brain. Dr. Robins well-known skill as a pathologist lends wei diagnosis, informs me that the case was a we one of rapidly growing tumor of the brain the motor areas about the fissure of Roland far as the diagnosis could be made clini doubtedly sarcoma. Syphilis especially was excluded.

I am well aware that these cases are no criticism, especially on the ground of the al some of the cases, of a microscopic exa This, however, was unavoidable, and in no cases, except possibly the last, could there real doubt as to the nature of the disease.

In Case IV. the long interval which ap exist between the last appearance of the the wife and its occurrence in the husb seem to deprive the case of all significanc we consider, however, the extremely slow the original tumor, as seen in Mrs. E., h similar one might exist in the abdominal ca out giving rise to symptoms the objection l of its weight. The length of time also tha histologically malignant may remain later trasted with the frequently rapid growth of or similar tumors is, I think, not sufficien ciated by pathologists, and offers anothe analogy to tubercular deposits. When a tur has remained quiescent for many years, grow and take on the character of malign geons are apt to assume that it has underg tological change from a benign to a growth. The following cases tend to pro least sometimes the assumption is unwarran

Case VI.—A small tumor, about one-ha in length by one-fourth of an inch in width, to the skin, but situated in the subcutaneou tive tissue, was removed by Dr. Markoe back of a healthy man, where it had existed years, with, I am informed, little or no ch ing that time. The tumor is a small r spindle-celled sarcoma, with little intercel stance, and having histologically all the of malignancy.

Case VII.—Minnie M., æt. 18, 'sing family history, noticed a tumor of the ne the lobe of the left ear, three years ago. about the size of a pigeon's egg, and re conglomerate of enlarged lymphatics. Pat that it has scarcely grown or altered s noticed. Extirpation May 25, 1885. M examination shows it to be a myxo-sarcom tologically very malignant.

Case VIII.—Miss T., tumor in the san precisely similar to the former, occurring in woman, æt. 21, has existed for five or six grown almost imperceptibly. Patient desi tion only because a brother had died about previously of sarcoma of the pharynx. E by Dr. Sands, January 23, 1884. Micros amination shows the tumor to be almos similar in structure to the last.

The possibility of direct inoculation of t subject or of animals with malignant disease much discussed, and many experiments m

Digitized by Google

point of injection was found a melanotic tumor, the size of a thaler, and pigment in the lymph vessels and neighboring lymphatic glands. The lymphatic glands, including the bronchial, were enlarged and pigmented. Lungs free. The same material was injected into the peritoneal cavity of a second dog, which was killed forty-three days later. At point of injection and in the mesentery were deposits of pigment. In one horn of the uterus were two pigmented tumors. Few glands were affected; one much enlarged inguinal gland. The bronchial glands were pigmented, but this was possibly from the lungs. All the pigment was in epithelial cells, but these were not similar to those of the tumor injected.

There is another way, however, of studying the subject. It will not be denied that there is not at present a pathologist of eminence who does not teach that malignant tumors are at first purely local. Could it be shown that carcinoma and sarcoma could be transmitted from man to man or from man to animals, the idea that nothing but the cell was inoculated would not be able to hold its place in scientific opinion for six months. We have passed the stage when it was possible to believe that an infectious disease can be of spontaneous origin. Yet if the disease be at first purely local the inoculation of a distant portion of the body in the same patient, the so-called contact infection is as valuable as the inoculation of another person would be. Cases of this kind are not rare in literature. The chief received instances are the following:

Dr. M. Nedopil† quotes a case narrated by Lücke of ulcerated carcinoma of the edge of the tongue, with inoculation of the mucous membrane of the cheek on the same side; a case by Kauffmann, in which a woman had cancer of the dorsum of the right hand, and, subsequently, of the conjunctiva of the right eye. Her relatives stated that she constantly wiped the right eye with the back of the right hand. Cases by Ahlfeld,‡ Hegar,§ and Spiegelber,‖ of direct inoculation of the vagina from the uterus; and cases by Klebs of inoculation of cancer of the tongue in the stomach. J. Reincke[25] gives two cases in which carcinoma developed in the punctures made to relieve ascites due to carcinomatous peritonitis. Prof. H. Quincke[26] gives a similar case. C. Bartsch,[27] in giving statistics of carcinoma of the lips, penis, and vulva, relates one case of possible contact infection. P. Kraske[28] gives two cases of rectal carcinoma in which small secondary tumors were found at a lower point, separated by healthy mucous membrane from the primary growth, and refers to Virchow's[29] well-known observation on the peculiar distribution of carcinoma of the peritoneum secondary to carcinoma of the stomach; to the cases of Lücke,[30] Kauffmann,[31] and Klebs[32] mentioned above, and to a case by Erbse,[33] in which a carcinoma of the œsophagus perforated the trachea, and gave rise to secondary tumors in the lower lobes of the lungs.

Beck[34] records the following three cases from the Institute of Chiari, Prague:

1. Ulcerating cancer of œsophagus. In anterior part of lower end of œsophagus and in stomach tumor of the same character—flat epithelial carcinoma.

2. Two carcinomata of the œsophagus separated by healthy tissue. The author admits the possibility of both being primary.

3. Multiple lymphadenoid round-celled sarcoma of most of the lymphatic glands, the lungs, spleen, and posterior surface of the stomach. In the ileum numerous similar nodules, not corresponding to Peyer's patches. In the cæcum an infiltration of almost the whole intestinal wall. The author excludes, on various grounds, all the other situations, and considers the growth in the cæcum as primary, and the other tumors in the intestinal tract as due to contact infection, the tumor particles being carried back by antiperistalsis; the tumor of the cæcum being ulcerated, and having caused much obstruction.

Beck quotes also a case by Hjelt, of carcinoma of the ileum and colon, with primary cancer of the duodenum.

Two cases of the kind have come under my own observation, as follows:

CASE IX.—Mr. A., an elderly gentleman, probably between 50 and 60, suffered for several years from a slowly growing epithelioma of the floor of the mouth on the left side, and encroaching on the posterior surface of the gum. Several operations were performed by Dr. Sands at varying intervals, with temporary success; but recurrence, after periods varying from two or three years to several months. After the fourth operation, December 18, 1884, rapid recurrence took place. A flat epithelioma developed on the hard palate, first at the point where the tip of the tongue, constantly in contact with the epithelioma in the floor of the mouth, would frequently impinge. The diagnosis in this case was confirmed by repeated microscopic examinations.

CASE X.—Mary M., æt. 44, single, March 29, 1885, family history good; no case of malignant disease known. Carcinoma of right mamma first noticed two years ago. Amputation of breast one year later. Axilla not opened. Recurrence noticed last October. Patient first seen March 29, 1885, suffering from carcinoma recurrent in cicatrix of operation; the new growth extending as nodular masses, ulcerated in part over almost whole of the right side of the thorax; anteriorly, laterally, and posteriorly to the external border of the scapula. Axillary gland on the same side much enlarged, and the whole right extremity enormously swollen, œdematous, and painful. On left side of the thorax, above the mamma, and on the left shoulder, are several isolated, not ulcerated, cancerous nodules, varying in size from that of a split pea to three-fourths of an inch in diameter, and not extending beneath the skin. Profuse sero-purulent discharge from the ulcers. Patient was last seen June 23, 1885, when the carcinoma had extended over the upper part of the abdomen, and a great part of the right scapula and shoulder. Ulceration of the carcinomatous masses in the axilla had occurred. The discharge from the ulcers on the shoulder and in the axilla constantly runs down on the anterior and internal surfaces of the arm and forearm to the wrist, exciting an eczema and inducing the patient to scratch. *All along this surface are cancerous nodules in the skin*, generally ulcerated or excoriated on the surface; some iso-

Prof. Bollinger, Epithelioma Contagiosum Beim Haushuhn, Virchow's Arch., 58, p. 340; ref. in Schmidt's Jahrb., 161, p. 296, describes a highly contagious disease in the common fowl, characterized by the appearance of numerous small tumors, having the exact histological structure of epithelioma. Dr. V. Izquierdo, Santiago, Chile, Spaltpilze bei der Verruga Peruana, Virch. Arch., Bd. 99, H. 111, 1885, p. 411. The disease is a *contagious* one, endemic in Peru, characterized by the formation of small multiple tumors in the skin. The author summarizes as follows: 1. "The tumors which form in the skin of those affected by the 'verruoa' are true neoplasms of the connective tissue, which always develop in the skin or subcutaneous connective tissue." 2. "Their structure is very similar to that of the sarcomata; in many parts are found which consist only of cavernous tissue." 3. "In these neoplasms, a special variety of microorganism (Spaltpilzen, described as bacilli) is found in great quantity, either lying between the anatomical elements, cells, or fibres, or contained in the bloodvessels, which they sometimes completely obstruct," etc.

Dr. Belleli, Alexandria, Progrès Médicale, No. 30, 1885; ref. in Lancet, Sept. 15, 1885, p. 300, describes a fibro-adenoma of the rectum, apparently produced by the presence of the ova of Bilharzia, in the tumors. This structure of the tumors in these cases is homologous and regular, because of the non-development of the ova; that a continued and increasing source of irritation would have resulted in the formation of a typical epithelial growth—a true cancer.

sibility to pain may precede that of temperature.—*Archives Générales de Médecine*, October, 1885.

THE TREATMENT OF THE PEDICLE IN HYSTERECTOMY AND OVARIOTOMY.—KŒBERLÉ, *Journ. de Sociétés Scien.*, 1885, No. 18, in a discussion of the treatment of the pedicle in ovariotomy and hysterectomy, held the view that the common results in ovariotomy are not traceable to antisepsis alone, but to simplification of the operative technique, namely, upon the intraperitoneal treatment of the pedicle.

By the application of the *serre-nœud*, it was held, septic material forced itself along the pedicle into the abdominal cavity, and the shortness of the pedicle frequently caused pressure upon the abdominal walls, thus impeding circulation.

The dropping of the pedicle into the abdominal cavity obviates all these difficulties. The skin wound heals by first intention: septic infection, accident with the pedicle, strangulation of the intestine, and abdominal hernia seldom occur, while healing quickly occurs. The controlling of hemorrhage is a point requiring special care.

For this purpose cauterization of the pedicle is to be recommended, nevertheless several ligatures are to be applied. In one hundred ovariotomies, in which the extraperitoneal treatment of the pedicle was used, Kœberlé stated his mortality to be eleven, while in seventy-four cases in which the pedicle was dropped into the peritoneal cavity but five deaths occurred. The ligature must be made of Chinese silk, and firmly knotted.

In the operation of hysterectomy Kœberlé held that dropping the pedicle is only practicable when it is not too thick; when this condition exists, the extraperitoneal method must be adopted.—*Centralblatt für Gynäkologie*, No. 59, 1885.

TREATMENT OF HEMORRHOIDS BY FORCED DILATATION.—DR. ROSIÈRE, in an inaugural thesis, discusses the treatment of hemorrhoids by forced dilatation, and considers the indications for this measure to be the existence of pain and hemorrhage.

As a permanent cure for the condition, its efficiency is not satisfactorily proven, but it possesses the advantage of being applicable in cases where diathesis enters into the question of treatment.

The treatment of hemorrhoids by cauterization, as successfully managed by Professor Richet by means of a forceps combining the advantages of the cautery and écraseur, is highly commended, and described. The first step is to draw down the hemorrhoidal tumor, and surround it with a moistened pad to protect the buttocks from the heat of the cautery. The tumor is then perforated in three points with copper wire, care being taken to permit tissue to intervene between the wires, in order to prevent retraction. Each of the pediculated points is then compressed by the jaws of the forceps brought to a red heat, and the hemorrhoids give place to small dark stumps, no thicker than a sheet of paper.

This method of treatment has been followed by Prof. Richet in 160 cases without a single death. As a radical cure it is preferable to all other operations, and particularly to forced dilatation, which is frequently unsuccessful, and which is best adapted to those cases in which a surgical operation is feared by the patient.—*Revue de Thérapeutique*, October 1, 1885.

THE HÆMOSTATIC USE OF ANTIPYRIN.—E. CASATI (*Raccoglitore medico*, August, 1885) reports the successful application of antipyrin in four and five per cent. solutions, as a hæmostatic. The results attained by its use seem to warrant the following conclusions:

1. Antipyrin is a powerful hæmostatic.
2. It is superior to perchloride of iron because after its use the wound remains entirely clean.
3. It is superior to ergot because only in extremely large doses does it manifest a toxic action, while according to Huchard it exerts a hæmostatic action whether applied directly to the bleeding part or administered internally.
4. In many cases it is to be preferred on account of its antipyretic as also perhaps for its antiseptic effect.
5. The hæmostatic action is manifested in a very short time.
6. Further observation is necessary to determine its value in controlling secondary hemorrhage.—*Gazzetta degli Ospitali*, September 30, 1885.

RESORCIN IN THE TREATMENT OF GONORRHŒA.—DELLERBAUGH recommends the use of resorcin combined as follows, in injections, for the cure of gonorrhœa:

℞.—Zinc. acetatis . . .	gr. ¼ to gr. ½
Acidi boracici . . .	gr. xx.
Resorcin	ʒj.
Aquæ dest.	fʒiv.—Misce.

S. Inject two drachms three times a day.—*Revue de Thérapeutique*, October 1, 1885.

A NEEDLE FOUND IN THE CAVITY OF THE CRANIUM.—RUDOLF V. HÖSSLIN, in the *Deutsch. Archiv für klin. Med.*, Bd. xxxvi. Hft. 5 and 6, reports the case of a man, aged 52 years, in whom a rusty needle was found upon the dura mater, at a point corresponding to the posterior superior angle of the parietal bone. One end of the needle had perforated the dura and reached the parietal convolution without occasioning any change in the cerebral tissue. The fixation of the needle had occurred through proliferation of connective tissue. No abnormality was discoverable in the bone, or in the soft tissues.

V. Hösslin further calls attention to four cases, previously reported, in which needles have reached the cranial cavity by an unknown path, and in which no notable changes were produced by their presence.—*Centralblatt für klin. Med.*, October 3, 1885.

PORRO'S OPERATION.—DR. ANDRONICO BARSOTTI, on September 2d, in the Maternita di Lucca, performed a Porro's operation, which resulted successfully, the lives of both mother and child being saved.

The presence of extreme deformity, due to osteomalacia, necessitated the operation, which was performed early in labor, and with strict antiseptic precautions.

The uterus was incised *in situ*, and compression of the pedicle made by an iron wire fixed upon a Cintrat's *serre-nœud*.

The operation lasted forty-five minutes. The ligature came away on the eleventh day, and the patient's temperature, subsequent to the operation, was normal.—*Gazzetta Medica di Torino*, October 5, 1885.

or eight weeks after the commencement of the disease, the presence of the patella reflex, from five to eight weeks after the recovery from the disease, as certainly happens, does not guarantee that the patella reflex will not disappear later, and that he who, up to this time, has remained free from serious disturbance of the central nervous system, will not ultimately suffer therefrom. On the other hand, the patella reflex may not be found a few weeks (three or four) from the commencement of the disease, while the patient, save the paralysis of the veil of the palate and slight disturbance in the function of the arches, feels perfectly well, and may remain permanently free from grave complications.

4. The disappearance of the patella reflex after diphtheria appears frequently to occur only on one side; likewise, in its restoration, it seems regained only on one side, or at least is plainly stronger on one side than on the other.

5. Disappearance of the patella reflex having once occurred, its absence may be remarkably persistent (five or six months), even when the patient, having been cured, presents no other symptoms of having suffered from the disease, such as ataxia or paresis.

6. This fact appears to possess certain importance in those researches which tend to establish the presence or the absence of the patella reflex in persons restored to health, who, having suffered from an attack of diphtheria, cannot be enumerated among the cured until after five or six months.

7. Whether the patella reflex may not only be preserved during the first five or eight weeks after the disease, as certainly happens, but for months, or in a word is never lost, the author has not yet been able to establish with certainty.

8. The cutaneous reflexes and the tendon reflex are not affected to an equal degree; the former are frequently found active, while the latter fail entirely, a fact which, observed even in tabetics, leads, according to the author, to the conclusion that the processes for the production of these so-called tendinous reflexes are distinct and not yet as sufficiently investigated, as those noted in the production of cutaneous reflexes.

9. The observations upon the disappearance or failure of the tendon reflex after diphtheria, have special value when the functions of the quadriceps extensor femoris are intact, when atrophy does not exist, and when the electrical excitability of this muscular group has suffered no profound disturbance and the patients are able to extend the leg freely and vigorously.

As to the explanation of this condition, that it may develop from the effect of acute infectious diseases, the author agrees with those who believe that it probably depends upon a disturbance of the function and nutrition of certain portions of the central nervous system, depending upon the emigration or development of germs.

The loss of the tendon reflex and ataxia are not in direct relation with each other. Both symptoms may be distinct and isolated. Tabes and diphtheria resemble each other in the fact, that the loss of the tendon reflex precedes ataxia, and frequently is manifested only on one side; but in diphtheria ataxia either follows in a few weeks or is entirely absent, while in tabes it frequently is not manifested until after the lapse of some years. A further distinction is, that the tendon reflex, when lost as a result of diphtheria, very generally is re-established—an occurrence extremely rare in tabes.—*La Medicina Contemporanea*, September, 1885.

THE IMMEDIATE IMPROVEMENT OF HEARING FOLLOWING DIVISION OF CICATRICES IN THE MEMBRANA TYMPANI.—H. BENDELACK HEWETSON, acting upon the suggestion of Professor Politzer, that the hearing may frequently be improved by dividing the cicatricial band in the membrana tympana resulting from healed perforation, reports two cases in which the operation was performed with favorable result. He says:

The first case in which I performed the operation was in a hospital patient of mine, attending my aural clinic at the Leeds General Infirmary. He came under treatment in March, 1884, and was then suffering from chronic otorrhœa following suppurative otitis, with a perforation in the left membrane, about the size of a No. 4 shot, straight below the handle of the malleus. So soon as the discharge was healed (under treatment by injection of a one in sixty solution of carbolic acid, after which iodoform was blown into the ear, which took place in two months and a half), it was evident that the boy did not hear so well. Originally, the discharging ear was the better of the two, the hearing in the other being almost lost from neglected chronic catarrhal deafness, associated with attacks of catarrhal otitis in childhood, but without a perforation in the tympanum. I waited some months, in order to give the cicatrix time to contract to the full; and, in February last, seeing that there was no improvement in the hearing, I divided the semilunar cicatricial band, where it was visibly the thickest, in two places, by means of a Gräfe's cataract knife. Before doing so I carefully tested his hearing. With the right ear he heard my watch at two inches distance, and not at all with the opposite ear. Immediately after division he heard the same watch six inches off, and could hear conversation much more easily, although he could not hear a whisper.

The sections in the membrane were about $\frac{1}{32}$ of an inch deep, and they visibly gaped, thus showing clearly the way in which the hearing became improved, namely, by releasing the cicatricial drag on the handle of the malleus. Testing the hearing a month from the operation, I found the hearing-distance from the watch still the same, but I thought that he did not hear conversation quite as well.

The second case which I have to report was in the person of a man, aged 52, who had had suppurative otitis at 14, during an attack of scarlet fever. In the left ear there was a thick semilunar cicatricial band surrounding the space formerly occupied by a perforation. The watch was heard only on close and firm pressure; but, on division of the cicatrix, slightly away from the ear, about a quarter of an inch. The most marked improvement, however, was for conversation, the man volunteering at once that the voice-sounds were heard much louder with this ear, which previously was almost useless for conversational purposes.

I only operated on the second case a fortnight ago, but, up to now, he says that his worst ear is the best. In this case I only divided the cicatrix once, to the extent of $\frac{1}{16}$ of an inch, about the centre of the semilunar curve.—*The British Medical Journal*, October 17, 1885.

cibly than ever, by the opportune investigations of PROF. E. S. WOOD, of Boston, papers printed with red, brown, and blue arsenical pigments, are more frequently met with at present than the greens, which were formerly alone deemed deleterious to health.

In the last volume of the report emanating from the Massachusetts State Board of Health, Lunacy, and Charity, Dr. Wood gives in illustration of his excellent article on arsenic as a domestic poison, six pages, upon which are pasted small slips of thirty-four wall papers; one of calico, and one of turkey-red cotton fabric, all, with a single exception, more or less charged with arsenic. Some of these samples are pink and gold, others dark brown on a yellow or light brown ground, several are red, and a few only are green enough to excite apprehension among the verdant. The amount of poisonous metal per square yard varies from half a grain up to fifty-five grains, and the price from twenty cents to three dollars a roll. The single specimen of this series which analysis proved to be free from arsenic, is light green in color, and is quoted at the lowest price above mentioned, so that it is evident that inexpensive, non-arsenical, green pigments, suitable for use in the printing of paper hangings, can be supplied. A very significant fact is, that samples of the more highly charged arsenical papers, some of which contained as much as two hundred and eighty-eight grains in each square yard, are omitted, because they produced extremely disagreeable effects in the workmen who merely handled those furnished in a previous volume of these reports, during the process of binding.

Of other papers, those called by the trade "glazed and plated," and used largely by children in kindergarten schools, are probably the most dangerous. Certain of these, chiefly red and green, contain a large quantity of arsenic, which notwithstanding a reasonable amount of care on the part of teachers, is liable to find its way into the stomachs of young children, who handle the slips of paper, and not infrequently place them between their lips. It is quite probable, as suggested by Dr. Wood, that many cases of irritable stomach and of indigestion, ascribed to taking cold, or to some indiscretion in diet, are really due to mild arsenical poisoning produced in this way. The red, brown, and blue papers of various shades, used, for example, as wrappers for confectionery, making tickets, and covering boxes, are often highly arsenical. One sample mentioned as being of the kind used in the manufacture of band-boxes, was so impregnated with the noxious metal, that a small box of this kind with three square feet of surface, would have in its composition about one hundred grains of arsenic. Painted balls, India-rubber dolls, and especially toy candles, were also found to be sources of danger; one small green candle contained nearly a grain of arsenic, which must of course be volatilized, and distributed through the air of any room in which it is burned. Serious examples of arsenical poisoning have been traced to the use of a certain kind of glaze upon linen or paper collars and cuffs, the surprising amount of ten grains of arsenic being obtained from a single one of these articles of dress.

Prof. Wood has collected the records of over forty cases in which poisoning is reported to have occurred, chiefly from exposure to the dust of arsenical wall papers. From an analysis of these, he concludes that the local symptoms are those of irritation of the eyes, nose and throat, or of headache, nausea, and diarrhœa. The former group of disturbances is apt to be attributed to a common cold, whilst the latter derangements are liable to be mistaken for a fit of indigestion, or a bilious attack. The general symptoms due to the action of the poison, after it has been absorbed by some of the mucous membranes, comprise neuralgia, dizziness, severe headache, nervous prostration, trembling of the limbs, and attacks of syncope.

Curiously enough, an avenue for the disposal of red, brown, and blue wall papers, with which manufacturers appear to have overstocked the shops, seems to be opened by the suggestion that in miasmatic regions, the inhabitants should systematically respire the air of rooms decorated with these poisonous paper hangings, during the season in which malarious disorders are prevalent. According to Tomasi-Crudeli, the amount of arsenious acid necessary for fortifying the adult human organism against ague, is from one-thirtieth to two-fifteenths of a grain daily; and direct observation upon individuals residing in marshy localities would soon determine how many hours per day patients should inhale air charged with the arsenical dust from the walls of particular rooms, in order to introduce a sufficient amount of the counterpoison into their systems.

THE CAUSES OF ANEURISM.

FROM the earliest times in which aneurisms were recognized, attempts have been made to account for their occurrence. But most of these have met with little success, and the original cause of aneurism is almost as much in the dark now as it was in the days of Galen. But two recent contributions to the study of this subject throw a certain amount of light upon it. One of these is a paper in Langenbeck's *Archiv für klinische Chirurgie*, xxxii. Bd., 3 Heft, by DR. CLEMENS RICHTER, who, writing from San Francisco, has made an elaborate analysis of the conditions in which aneurism attains so striking a prevalence, as it does in, that city. In doing this, he has examined, among other things, the nativity of the citizens of San Francisco, and compared the ratio of the cases of aneurism there with that which is found

THE RELATION BETWEEN THE DEVELOPMENT OF THE ROUND LIGAMENT AND THE CONTRACTIONS OF THE UTERUS.

FREUND'S *Gynäkologische Klinik*, published recently at Strassburg, contains a brief contribution from DR. HOMBURGER upon the relation between the strength, or development of the round ligament and the action of the uterine musculature.

Dr. Homburger refers to the three factors which enter into the question as to the favorable progress of a labor, viz,, the bony passage, the soft parts of the pelvis, and the size of the child. He observes that the means by which we ascertain the size of the child, and the condition of the uterine musculature are as yet very uncertain. So far as examination of the latter is concerned, the result obtained is incomplete, since only one side of the uterus can be palpated.

Professor Freund first suggested a possible relation between the thickness of the round ligament and that of the uterine muscular wall. The office of the round ligaments has been recognized as contributing, in the latter part of pregnancy, to the descent of the fœtal head into the pelvic cavity, and, in labor, as drawing the fundus of the uterus forward, and assisting the pressure of the ovum upon the os uteri during labor pains. But hitherto, no one has sought from the development of these ligaments to make a prognosis as to the progress of the labor.

Dr. Homburger states that in almost every pregnant or parturient woman the round ligaments can be felt through the abdominal covering; and especially the left ligament, it generally having a greater circumference, and being more distinct than the right. In examining 270 women, he failed to feel them in only two. He further states that there is a relation, on the one side, between the development of the round ligaments and of the uterine wall, and, on the other, the forces of the "contractions." One can, if there be a well-developed ligament and uterine musculature, reckon upon vigorous uterine contractions. Very weak contractions never come with a strong ligament. His conclusions were drawn from numerous cases. In eighty-one where the ligament was found quite thick, there were only two which showed defect in the labor activity. In twenty-six cases where the ligament was moderately thick, there were only seven in which the contractions of the uterus were fully normal.

In deciding as to the normal action of the uterus, one finding the normal ligaments unequally developed, this being usually the case, selects that which is the thicker, in order to predict from it the character of the uterine contractions. Further, in this decision a very positive preference is to be given to the examination of this ligament over palpation of the uterus.

Why the left round ligament should be in almost all cases larger than the right, is not easily explained. Certainly the former is more readily examined than is the latter, for the pregnant uterus usually undergoes a partial rotation by which its left side is thrown more toward the anterior abdominal wall, while its right recedes posteriorly. This rotation is probably derived from an embryologic condition; for, when Müller's ducts are brought in apposition for the development therefrom of the uterus, the left duct is somewhat further in front than the right, because thrust forward by the terminal portion of the intestine at the left, and fusion takes place in an oblique position. This normal rotation of the uterus in pregnancy may cause increased strain upon the left ligament, and hence its development may be greater than that of the right ligament.

REVIEWS.

MICRO-CHEMISTRY OF POISONS, INCLUDING THEIR PHYSIOLOGICAL, PATHOLOGICAL, AND LEGAL RELATIONS; WITH AN APPENDIX ON THE DETECTION AND MICROSCOPIC DISCRIMINATION OF BLOOD. ADAPTED TO THE USE OF THE MEDICAL JURIST, PHYSICIAN, AND GENERAL CHEMIST. By THEODORE G. WORMLEY, M.D., Ph.D., LL.D., Prof. of Chemistry and Toxicology in the University of Pennsylvania. With ninety-six illustrations upon steel. Second edition. 8vo. pp. 784. Philadelphia: J. B. Lippincott Company, 1885.

THE dominant and lasting impression produced by an examination of this work, is a conviction of its absolute trustworthiness. The work bears direct internal evidence of the careful verification of literally all of the principal tests and methods given. An illustration, and one by no means unimportant, of the reliability of the book is seen in the fact that the numerous citations of medico-legal cases are drawn exclusively from the official records.

To those already acquainted with either edition, any mention of the exquisite delicacy and accuracy of the plates which illustrate the volumes is needless. They bear the same relation to the classical drawings of Funke as did these latter to the designs of earlier observers.

The work has been thoroughly revised and much enlarged in matter, especially by the addition of illustrative cases, largely American, and by new tests and methods for recovery of poisons from organic mixtures. The more important additions to the work in its present form are seen in the full appendix on the chemical recognition and microscopical discrimination of blood, and in the chapters on the Ptomaines and on Gelsemin. Three of the sixteen steel plates, together with a colored plate of the blood-spectra (chiefly remarkable for the accuracy of its measurements) are also new. Throughout the book the new chemical nomenclature has been substituted for the old.

SOCIETY PROCEEDII

NEW YORK COUNTY MEDICAL AS

Stated Meeting, October 19, 18

THE PRESIDENT, CHARLES A. LEALI
IN THE CHAIR.

DR. FREDERIC S. DENNIS read a paper

FRACTURE OF THE PATELLA, WITH ILLU CASES.

It was devoted to the treatment of this wiring together the fragments, the proce revived by Mr. Lister, and Dr. Dennis saic to present all the arguments both for anc method. It was first performed by the l Rhea Barton, of Philadelphia, in 1834, ar by McClellan, Logan, Gunn, and other surgeons thus being the pioneers by many as in a number of other important operatio

There are at present two classes of surg present surgical opinion on this subject. composed of those who regard it as a perfec procedure, and, when performed with prop precautions, unattended with danger. noted, however, that previous to the year cases out of forty-nine had terminated fat six suppuration and anchylosis had followe tion. Since 1883, however, much better been noted. He was unable to state the e of operations which had been done, but a would place them at more than fifty, and i of cases no patient had died. Out of the fi tion had been reported in three; but one o case of compound fracture of the patella then it is to be expected that there will be a

The second class of surgeons is compos who are of the opinion that this operation i justifiable on account of the great risk incur ing the knee joint, and who claim equally for the older methods.

Dr. Dennis stated that personally he had sixty cases of fracture of the patella altogeth previous to adopting the operation of wiri ments together, he had obtained the best the method of the late Dr. James R. Little, of Paris. He had seen only a few cases, hov the union was osseous and the fracture of t perfectly restored. Having remarked that tained as good results as with the method o fragments, he exhibited a specimen of bony fractured patella, which he said he believed one of its kind. It came from a case whic treated by one of the older methods, and nection he referred to a patient now under St. Vincent's Hospital, in whose case, altho 88 years of age, bony union had been s then stated his firm conviction that moder surgery could show as its results both osseou perfect joints, which every surgeon knows t of obtaining by any of the older methods.

The metallic suture in fracture of the with certain restrictions, an ideal operation.

Digitized by Google

the operation had nothing whatever to do with the fatal result. Within twenty-four hours he had two cases of fractured patella in different hospitals. One of them died in six days, and at the autopsy the joint was found to be perfectly aseptic; death having been due to delirium tremens and Bright's disease. The specimen from the case which he now exhibited was entirely unique, he said, as it showed firm bony union in only six days after the operation. No callus was found, and the union was analogous to primary union in the soft tissues.

Second, the superior results as regards the functions of the limb and the joint. Under the use of the older methods a separation of the fragments of half an inch was regarded as a very good result, and Malgaigne stated that he had never seen a perfect result after fracture of the patella. Dr. Dennis having enumerated a long list of evils which are likely to follow this accident when treated by the former methods, claimed, in contrast, that with wiring the fragments together a perfect joint, with perfect restoration of usefulness, can be obtained.

Third, the greater rapidity of repair. In a case of his own the patient was walking about in eight weeks, and in one of Dr. Phillips's, in three weeks and three days; while a patient of Dr. Hinton's walked nearly a mile at the expiration of six weeks. He believed that, as a rule, it will be found that in two weeks union is sufficiently firm to enable the patient to walk. This gain of time is certainly a very important matter, not only to the day-laborer, but to the professional and business man also. Formerly, however, the patient was laid up for at least three months, and the limb was not strong for two years.

It is true that the Academy of Medicine in Ireland and Société de Chirurgie have pronounced against the new operation; but he has no doubt whatever that the tide of professional opinion will soon turn in its favor. The case is altogether analogous to that of abdominal section in surgery, in regard to which such a complete revolution of sentiment has occurred. It has been stated that the knee-joint is liable to the formation of osteophytes after this operation; but this is merely a fanciful objection. Another objection put forth is that rarefying osteitis is likely to occur, but he has never seen such result.

The conclusion of the paper was devoted to a description of the technique of the operation. In the first place, he said that wiring the fragments ought not to be undertaken immediately after the accident in simple cases, as it is liable to set up inflammatory action under these circumstances. It is better, therefore, to wait a few days. In compound fractures, however, the operation is to be performed at once. The strictest antiseptic precautions are invariably to be observed, and among them are the free use of iodoform and ether, the application of bichloride solution (1 to 2000) to the parts above and below, and the continuous irrigation of the wound with the same solution from the beginning to the end of the operation. Personally, he prefers the transverse to the longitudinal incision, which is the one more commonly adopted. The joint having been laid open, all blood-clots are to be removed, and the anterior fibrous capsule elevated from between the two fragments. The holes in the bone for the sutures, as had been mentioned, are bored with an Archimedean drill, the passage of the wires being assisted by a groove; no harm comes from leaving the wires in the wound. After the latter is closed, a plaster-of-Paris splint is to be applied, and the patient kept in bed.

Dr. Dennis gave his conclusions somewhat as follows:

(1) In compound fractures of the patella there is not the slightest doubt of the propriety of the operation. The cases of Dr. Fowler, himself, and others demonstrated its practical usefulness.

(2) In recent and old fractures, under ordinary circumstances and with the patient's consent, it is wholly justifiable.

(3) In debilitated patients and those suffering from organic diseases, the operation should not be performed.

(4) It is not an operation which can be indiscriminately performed. It should never be undertaken by the inexperienced or by those who have not the most complete faith in the efficacy of antiseptic surgery.

(5) Success depends on the most thorough carrying out of the minutest details of the antiseptic procedure.

(6) While the number of cases is as yet limited, the more and more extended adoption of the operation by the surgeons of America will soon cause it to be universally regarded as a most marked advance in treatment.

Dr. Dennis then proceeded to exhibit a number of very interesting cases. The first was his own case of compound fracture, where the patient fell from a scaffold. At the end of two months he said he had walked well, and at present it is evident that he has the most complete use of the joint and limb.

The second case was that of Dr. Fowler, of Brooklyn. which was the first case of compound fracture of the patella treated by the new method in this country, and which, he said, undoubtedly marked an era in the surgery of America. Dr. Dennis's case, just referred to, was the second. Dr. Fowler's patient was a female, and it was seen that she had a most useful limb; being able to bend it to more than a right angle at the knee. In this case Dr. Fowler had allowed the drainage-tube to remain in position for two weeks, while in his own it had been withdrawn at the end of three days.

The third case was that of a man who had fractured his patella less than three weeks ago, and yet the wound was entirely healed, and he was able to walk about on crutches. Three other recent cases were also exhibited, and all are doing well. Dr. Dennis expressed his regret at not having been able to present, in connection with this group of cases, that of Dr. Phelps, in which both patellæ were fractured. This patient, he said, is now walking about the streets as well as ever.

DR. FOWLER, of Brooklyn, being called upon by the Chair, said that he was always ready to say something in favor of conservative surgery, and he believed that the operation to which Professor Dennis had invited attention this evening is conservative surgery pure and simple. His own case of compound fracture, which had been referred to and exhibited, was a peculiar one from the fact that the upper fragment became necrosed, and had finally to be removed. After the operation of

Digitized by Google

wiring the fragments together, he had found it to have two drainage-tubes in position, and in allowing them to remain for two weeks wa believed it to be less dangerous to do so tl obliged to resort to frequent dressings. H that in antiseptic surgery as little change of as possible is highly desirable, and in this the first dressing was not changed at all un piration of fourteen days, when the drainage-t removed. He had also employed the same n cases of exsection of the knee and other la: which were cured in twenty days, with but change of dressings at the end of the tenth da the Archimedean drill employed by Dr. Denn greatly impressed with its simplicity and u but even if no such contrivance be made boring the holes, he could not see how such a could be required for this, as Dr. Dennis had i In his own case he had used an ordinary c: brad-awl, and the operation had not been a one. For introducing the wire through the hol employed a canula.

In this operation it is of great importance t the fibres of the aponeurotic surfaces from be fragments, as, if left there, they are extrem to prevent bony union. In cases of second the method of McEwen, to which he beli Dennis had not referred, and which consist ing saw-toothed incisions of the quadriceps is of great service in bringing the fragments It is the ordinary practice to hammer the tw of the sutures down into the periosteum, but doing this he had suggested turning them ir the fragments, as he believed this will give r irritation. In some cases he had also made rubber bridge beneath which the wire sutures withdrawn entirely after they had served their if required, and he considered this to be a point.

In conclusion, he said he could only expres cere appreciation of the efforts being made i tion with this operation, to prove beyond qu superiority of the antiseptic system of surgery, considers the most inestimable boon in this d of medicine since the introduction of anæs means of chloroform and ether.

DR. BURGE, of Brooklyn, remarked that he no experience with the heroic measures which the subject of discussion. He had hitherto himself that he had been able to bring the sir older methods of treating fractures of the pat greatest perfection; but after listening to what been said, he felt like a junior student, and h hesitate to assert that he believed he had deri benefit from what he had heard here than have done by a three months' trip to Europe.

DR. F. FORNÉ, staff-surgeon of the French N stationed on a man-of-war in New York Ha pressed through Dr. J. W. S. Gouley his pl being present this evening, and his convict what he had seen and heard, of the propri operation of wiring the fragments together i simple fracture of the patella.

DR. H. M. BIGGS, of the Carnegie Labora gave some

tion of a carefully prepared microscopical specimen, in regard to

NUMMULITES, FROM THE FOUNDATION STONE OF CLEOPATRA'S NEEDLE AT CENTRAL PARK, REMOVED FROM EGYPT TO NEW YORK IN 1880.

When the base of the obelisk was being placed in position, he said, a broken off-piece was given to Dr. P. C. Cole, who skilfully prepared this beautiful translucent specimen, one inch square, and presented it to me. I can easily remember the time when the huge piece of rock now supporting the obelisk was transported through the city, passing by my solidly built residence on Fifth Avenue, which it shook from foundation to roof, as the wheels of the heavy truck rolled on the Belgian pavement. This stone is called nummulitic limestone. It is of the middle Eocene period, and consists of limestone composed of nummulites, which are held together by a matrix formed of the comminuted particles of their shells, and of smaller foraminifera. The pyramids are built of this rock, which was taken from the Mokkadan Mountains in Egypt.

This nummulitic limestone, Dr. Carpenter informs us, is so vast in extent that it is often 1800 miles in breadth and sometimes several thousand feet in thickness, and it may be traced from the Atlantic shores of Southern Europe and Northern Africa, through Western Asia, to Northern India and China, and likewise over large areas in North America. It plays, as Sir Charles Lyell states, a far more conspicuous part than any other tertiary group in the solid framework of the earth's crust. Yet, when this extensive geological structure is examined microscopically, it is found to consist of minute shells, impossible for the human hand to trace, showing the fossil remains of one of the early evidences of animal life, a minute protozoan, characterized by having a calcareous shell perforated by pores or foramina. The older we live, and the more we investigate, the more do we behold the numerous mysteries yet to be solved. Our profession demands constant thought and ever-active brains. Life truly is short, but art is endless.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Stated Meeting, October 7, 1885.

THE PRESIDENT, J. M. DA COSTA, M.D., IN THE CHAIR.

DR. DA COSTA offered some

REMARKS ON THE TREATMENT OF ROSE COLD AND HAY FEVER BY COCAINE.

(See page 477.)

DR. HARRISON ALLEN remarked that he was glad to hear Dr. DaCosta state that the effect of cocaine is inconstant within a narrow range in different individuals. He had observed the same fact. In endeavoring to account for it, he had concluded that the difference lies in peculiarity of the erectile tissue. Those persons in whom the tissue is sparsely developed are, he thinks, less susceptible to impression by the remedy than are those in whom it is well developed. He recalled one case in which a four (as well as an eight) per cent. solution was used persistently without benefit. If, then, one has under observation nasal chambers with mucous membrane exhibiting but little erectile property (changing very little under any of the conditions, such as galvanism, which ordinarily constrict the capillary network), the remedy will give but little relief. He had had three such cases under care during the past summer. The shrinking up of the erectile masses places the nose in what may be called a normal condition, the air passing through at a normal rate and the irritated surfaces not touching each other. One of the cases in which relief was not secured, was that of a lady suffering from the annoyance due to complete occlusion. After applying the cocaine for half an hour there seemed to be a little relief, but it lasted only a short time. Nothwithstanding these failures he had no doubt that further experience will show the truth of the author's statement, that we have in cocaine a remedy which will, in the majority of cases, give relief.

DR. H. C. WOOD said that, in this connection, the observations of Dr. Lyons, of Detroit, may be of interest. He has shown that there are probably two or three alkaloids in cocoa leaf, and that the commercial alkaloid, cocaine, not rarely is composed of more than the one alkaloid, ecgonine, and perhaps a third alkaloid is present. The unexpected results sometimes obtained from the therapeutic use of cocaine may possibly be due to the presence of one of these other alkaloids.

DR. RUSCHENBERGER asked for information as to whether or not caffeine is capable of taking the place of cocaine.

DR. H. C. WOOD stated that he had made some experiments with caffeine on the eyes of patients, and found it to be without effect.

DR. ORVILLE HORWITZ then communicated, through Dr. Da Costa, his

OBSERVATIONS ON SUNSTROKE AND HEAT-EXHAUSTION.

(See page 485.)

DR. H. C. WOOD said that the use of musk, as detailed in the paper just read, he believed to be new. Antipyrin has, however, been used in one of the New York hospitals, and a paper written thereon by the resident physician.

There is one point which is worthy of consideration by hospital authorities. He has noticed himself, in experiments on animals, that time is of the utmost importance in the treatment of sunstroke, and our clinical experience accords with this. If the moment the animal became unconscious, he reduced the temperature by cold, the animal invariably recovered; if, however, it was left for ten or twenty minutes, reduction of the temperature caused benefit, and usually return of consciousness, but there were almost always marked signs of an impaired nervous system, and in a large proportion of cases death from paralysis. In the New York Hospital, antipyrin was given to the ambulance surgeon, and thus the remedy could be administered at once. He thought that in very warm weather the hospital ambulance should be provided, not only with antipyrin, but also with ice, and no time would be lost, the remedies being applied as the patient was being brought to the hospital. The patient could be half undressed and rubbed with ice, and antipyrin could be used hypodermically.

Very few writers report the time which has elapsed before treatment after the sunstroke; and without such

Digitized by Google

cases quoted in the paper under the initial D, had been in their termination in his care, and they had struck him as bearing upon the question of contagion closer than any he had ever encountered.

DR. POST said that one interesting feature of the tumor upon which he operated was, that altough the morbid growth did not extend into the antrum it had eroded its anterior wall so that he could pass his little finger into the cavity.

DR. SANDS was able to add another case to the list given by Dr. Hall, one in which malignant disease occurred in more than one member of the same family. A young man came to him three years ago on account of a swelling on the right side of the face over the spheno-maxillary and malar regions. It seemed to be due to the development of a tumor which was very deeply situated, and which, besides causing projection of the side of the face, was attended with a protrusion of the eye. He suspected the existence of a polypus of the spheno-maxillary fossa, and with a view to remove it he raised the malar bone, but was disappointed on discovering that, although a tumor was present in the spheno-maxillary fossa, it was not a polypus, but was firmly embedded and could not be removed. The patient was known to be living six months ago, in a state of great misery, the tumor having reached a very large size. About six months ago a brother of this patient was brought, in whom a tumor of large size had developed in the pharynx, within a few months. It filled the pharyngeal cavity and although it was not firm in consistence it was firmly attached. The disease was evidently malignant. The patient's general health had become very much impaired, and Dr. Sands was obliged to decline surgical interference. Probably both patients are now dead. They lived in the same house in Westchester County, and often occupied the same room.

It seemed to him that such cases, although they cannot be accepted as proving the contagiousness of malignant tumors, indicate very clearly the direction in which future inquiries should be made, in the hope of confirming the hypothesis of the parasitic nature of these morbid growths; for, certainly there is no disease not already proved to be parasitic, which seems so likely as cancer to have such a mode of origin.

DR. HALL remarked with reference to the remarkable absence of apparent contagion in literature, that it may be explained by the fact that, if the idea of specific poisons for malignant tumors is accepted, probably all cases recorded as of hereditary origin will fall under the head of infection. In tubercle practically the same thing is occurring now. Formerly all cases were attributed to heredity, whereas now they are very largely attributed to infection. Congenital tuberculosis is extremely rare, and while congenital carcinoma and sarcoma occur, they are also extremely rare.

Adjourned.

CORRESPONDENCE.

ANOTHER RESIGNATION FROM THE CONGRESS.

To the Editor of THE MEDICAL NEWS.

SIR: My attention has been called to the fact, that my name has been twice published in your journal as, so far as is publicly known, not having declined to accept office under the new Committee of the International Medical Congress.

I beg that, as soon as possible, you will make the fact public that, on August 31, 1885, I addressed a letter to Dr. John V. Shoemaker, in which I declined to have anything to do with the Congress under its present organization.

It would be especially gratifying to me if the date of my declination, as well as the fact of it, could be mentioned in your columns. Very respectfully yours,

JOHN G. CURTIS, M.D.

127 EAST THIRTY-FIFTH ST., NEW YORK CITY,
October 23, 1885.

HYDRAMNIOS.

To the Editor of THE MEDICAL NEWS.

SIR: In your issue of August 22d there is an abstract of several cases which have occurred of this most curious condition. A great many theoretical explanations of it have been given, but no one, so far as I can see, has yet drawn attention to the fact that every recorded case, —at least it is certainly true about all the cases that I have seen recorded, and all the cases which have occurred in my own practice—has been in twin pregnancy. Until this remarkable fact is got over, all other explanations may go to the winds. The cases have come to me with a single exception as ovarian tumors of rapid growth, and besides those that I have seen I know of several that have been most unfortunately tapped under the impression that they were ovarian cysts.

I am, sir, yours, etc.,

LAWSON TAIT.

BIRMINGHAM, October 5, 1885.

A METHOD OF MAKING THIN KID FOR TESTING EYE INSTRUMENTS.

To the Editor of THE MEDICAL NEWS.

SIR: On account of the great difficulty at times of obtaining the very thin kid that is used for testing eye instruments, I was led to search for a means of supply more accessible than that which has heretofore been available. After many trials, I devised the following method: As this kid consists principally of the epidermic layers, a piece of kid is chosen that has as thick an epidermis as possible (one that has not been scraped too much), and by means of a knife or finger-nail the epiderm at one of the corners is torn or split from the skin beneath. By great care, and working with the thumb-nails, the whole epiderm can be stripped off in one piece. According to the skill exercised, and the adaptability of the skin, will be the results obtained. The small pieces of true skin which are found adhering to the epiderm can be scraped off with a blunt knife, thus leaving a piece of kid as fine as the best Paris make. I was assured by a professional cutter that the kids used here is made by shaving, as he said he could see the marks left by the tool. I believe the kid we use is obtained from the instrument makers of Paris, and at Charriéres', in Paris, I was assured that they depended for their supply on an old man who only made the rounds at intervals. So you see the source of supply is exceedingly limited. Enclosed please find a sample.

BANDAGE FOR THE FIXATION OF THE HUMERUS AND SHOULDER GIRDLE.

To the Editor of THE MEDICAL NEWS.

SIR: In your issue for August 29, 1885, Dr. Dulle describes "A New Bandage for Fixation of the Humeru and Shoulder Girdle." I can add my testimony tha this method of bandaging is a most excellent one fc many shoulder injuries.

For several years past I have used it at the Massa chusetts General Hospital and in private practice. It essentially a figure of eight around the axilla of the we side and the elbow of the injured side, crossing over th injured shoulder. Its action in bringing pressure upo the top of the shoulder and at the same time driving th humerus strongly up toward the socket, makes it th treatment par excellence for cases of dislocations of th acromial end of the clavicle, for it holds the clavicl down and through the humerus it lifts the scapula unt the acromion can easily be brought on a level with th clavicle.

I have had the opportunity of applying it to thre cases of this rare injury and in all of them the recover was complete without deformity. Yours truly,

A. T. CABOT.

WASHINGTON.

(*From our Special Correspondent.*)

THE INSPECTION SERVICE ON THE CANADIAN FRO TIER, established by the State authorities of Michiga for the prevention of the introduction of smallpox int that State, has, at the request of the Governor of th State, been assumed by the Marine-Hospital Servic The reason for the change is the small fund at the con mand of the Governor, which may be required for oth purposes. The Governor, in notifying the Secretary the State Board of Health of the fact that the servic will not be any longer supported by the State, compl ments the Secretary upon the fact that up to the prese time no case of smallpox originating from Canada ha occurred in the State. Surgeon W. H. Long, of th Marine-Hospital Service, has assumed charge of th inspection service in that State.

The Keeper of the Life-Saving Station at Osweg N. Y., has been informed by the District Superintende that all tugs have been requested to make signal b whistle whenever they have Canadian vessels in to and that upon hearing these signals the surf-boat is be launched and will carry the Inspector of that static to the vessel, and if the vessel is found to be infected will be towed to quarantine, and the usual precautio taken. The Inspector lives at the Life-saving Statio and is ready at all hours to board vessels. A comple system of inspection checks is in use, which obviat the annoyance to passengers caused by reinspection the different stations, each passenger inspected beir furnished with a card giving full particulars of the la inspection.

both written and practical; 6th. The endowment of medical schools so as to secure fixed salaries for the professors, who would then cease to have any pecuniary interest in the size of their classes.

After highly complimenting McGill for having adopted many of these reforms years ago, Provost Pepper went on to say that, although much valuable instruction can be imparted by lectures, they cannot train the hand and eyes of the student in the investigation and recognition of disease. It is by means of the various laboratories of anatomy, chemistry, physiology, and pathology, and later in the wards of the hospital, that this, the most important part of the education of a medical man, is acquired. It is by these means alone that physicians can be produced who are neither routinists nor theorists, but clear-sighted, practical students of nature, as revealed in the myriad forms of morbid action and in the no less numerous agencies for the cure and prevention of disease.

The urgent necessity for more endowments of medical schools was dwelt on, and the establishment of competitive scholarships advocated. The Professor said that, although tens of millions, during the last fifty years, had been given for the support of classical and scientific education, the general movement for the endowment of medical schools is of very recent origin, and the number of large benefactors to such schools can be counted on one finger. The movement has begun, however, and he confidently expects to see it advance till deserving medical schools are fully endowed.

He alluded to the researches of recent years upon the nature and causation of consumption, diphtheria, and of cholera, and said that such investigations must be carried on in such laboratories as are now possessed by McGill University; but, in addition to the laboratories, men are wanted who are willing to devote themselves to those scientific researches; these can only be obtained by the endowment of fellowships tenable for one year or more. It may, he continued, seem extravagant to provide spacious rooms, expensive outfit, and large endowments, merely for the sake of the study of a few of the lowest and most minute forms of organic life; but, if such study leads to the discovery of the true cause of any one of those great diseases, it will be of more value to the world than all the gold fields of California.

In conclusion he said that, although he looked with proud satisfaction on such buildings and laboratories of equipment as those before him, we must not remain contented; the progress of medical science is rapid and unceasing, new fields of investigation are being continually opened up and new methods of research introduced; enlarged facilities will continue to be required from time to time, and ere long other spacious buildings must be erected. We advance with increasing confidence because assured of the coöperation and support of an enlightened public sentiment, and here in Montreal such confidence is not misplaced.

At the conclusion of his address Provost Pepper was loudly cheered.

PROF. OSLER, of Philadelphia, also gave a short address which was rapturously applauded by his old students. He dwelt on the great importance of laboratory work and the necessity for endowed chairs of fellowship, to enable young graduates to do original work. He congratulated the Faculty on the magnificent building they had erected, and contrasted the present condition with that of fifteen years ago when he was a student of McGill. Then the only practical laboratories were those of anatomy and chemistry; now in the new building, laboratories of practical physiology, pharmacy, pathology, and histology, had been added. He concluded by saying, that in the sixty odd years which had passed since the founding of McGill, the labors of those in charge had been extensive, and the work which had been accomplished had been grand, and he prophesied that in the next half century the progress will be equally grand if not grander.

The Hon. Senator Ferrier, Chancellor of the University, Sir William Dawson, Principal, Dr. R. P. Howard, Dean of the Medical Faculty, and others, then addressed the meeting.

DR. HOWARD said that the money taken from the $100,000 endowment fund of the Medical Faculty for the erection of the new building, had been only lent to the University, and that at some future time it would be returned to the Faculty.

After the speeches the guests were escorted over the building by the members of the Faculty, the students meanwhile enlivening matters by singing stirring college songs.

In the evening the Faculty entertained the benefactors, governors, and invited guests, at a banquet given in the Windsor Hotel. It was a brilliant affair and brought out some very fine speeches from prominent men.

The following is a short description of the present medical building, which is situated on the grounds of the University.

The main hall on the first floor is 136 feet long with a room 28 feet long at the end, giving a total length from front to rear of 164 feet. The whole building covers an area of about 14,000 square feet. On the ground floor on the left-hand side of the entrance, is the library, which contains over 10,000 volumes. This department has been enlarged by an addition of a room 30x22 feet. On the opposite side of the hall is the museum, the capacity of which has been almost doubled by the addition of a large room, formerly the practical chemistry laboratory. On the same flat is the new pharmacological laboratory fitted up for demonstrating experimentally the action of drugs as well as for giving courses in practical pharmacy. Opposite this laboratory is the students' reading-room. Going still further along the hall we come to the physiological laboratory (45x21) with the private room of the Professor, adjoining.

We now come to the new chemical laboratory (45x35), which is fitted up to accomodate between 75 and 100 students. The balance room and private rooms of the Professor of Chemistry and his assistants, open off the laboratory. Opposite the chemical and physiological laboratories is the new physiological and chemical lecture-room. The room is hexagonal in shape and 76 feet wide. It is lighted by windows and skylight and is capable of seating 275 students. Beneath the seats of the lecture-room are several small rooms allotted to the professors.

On the second story opposite the main staircase is the dissecting-room (72x31). This room is twenty feet high and well ventilated, is furnished with twenty tables,

THE HYGIENE OF THE ESKIMO, WITH SOME OBSERVATIONS ON THEIR THERMOMETRY TO DETERMINE THEIR PHYSIOLOGICAL NORM.

BY EDWARD H. GREEN, M.D.,

P. A. SURGEON, U. S. N.

DURING the cruise of the United States Steamer "Thetis" while in the Arctic, engaged in the relief of the Lady Franklin Bay Expedition, I made some observations on the general hygienic surroundings of the Eskimo; as to their food supply, their mode of procuring it, and the hygiene of their habitations. I did this as preliminary to making some observations with the clinical thermometer to determine whether or not a continuous existence in low temperatures had any effect in reducing the norm of physiological temperature. These observations were made with difficulty, owing to the non-coöperation of the subject in many instances, and only include some thirty-seven cases, but sufficient to make some deductions therefrom.

Our contact with the natives included those met with in Disco, Greenland, a settlement containing about 225 souls; those in Upernivik, numbering about 300; those in Tessuisak, about 80, and a nomadic tribe off Wostenholme Island, comprising about 25; these latter presented the pure type of Eskimo, without any Danish admixture.

The inhabitants of Disco, Upernivik, and Tessuisak are colonized, and live under Danish influence and laws, and may be termed semi-civilized. Most of them show evidences of Danish blood, being light in color, with a light tinge of hair and blue eyes, mostly short of stature, and well developed physically. Disco is in latitude 69° N.; Upernivik in 70°50', and Tessuisak in 72°. The range of temperature for the year is about the same in the three places. Through the kindness of Gov. Elbong, of Upernivik, I got the monthly mean temperature for 1883, and he said that it represented about the average according to his experience of twenty-five years in the country. In January, the average for the month was —18° F.; for February, —22° F.; for March, —27°; for April, +2° F.; for May, +15°; for June, +22°; for July, +29°; for August, +36°; for September, +28°; for October, —5° F.; for November, —12°; for December, —16°.

These observations were made with a thermometer having the Réaumur scale; the correctness of the instrument and the readings must be taken for granted; it is sufficient to show that the natives live in a temperature with a yearly average closely bordering on zero Fahrenheit. Their food is almost wholly animal, as it is only by forced cultivation and the greatest care that anything vegetable is raised as an article of diet, and this is only done by the Danish officials, in little improvised hothouses, the yield being scarcely sufficient to pay for the labor. In this way lettuce, turnips, and dwarfed potatoes have been cultivated. The different varieties of seal, principally the bearded variety (phoca barbata), called the oog jook, the small seal or floe rat (phoca fœtidus), and the common or Greenland seal; together with the walrus and occasional bear, and several varieties of Arctic birds; together with a species of codfish, constitute the variety of their food that is yielded by the country; in addition to this, the Danish Trading Company sends out every year a sailing ship, which touches at the different trading posts, and leaves a supply of tea, coffee, flour, and sugar, in exchange for the furs, blubber, eider-down, and ivory that may have been collected. The Governor of each place supervises the distribution of these stores.

The Eskimo seem to have a convenient appetite; they can go without food for long periods, or eat five or six times a day, just as they happen to have it. They are improvident of food, and do not begin to lay in their winter supply oftentimes till it is too late, when they suffer from lack of it and appeal to the Governor, who obliges them to give him a tithing, which is left in reserve. It is said that were it not for this supervision, during severe winters the natives would soon become extinct from starvation. I have never seen a native eat more than what I estimated as five pounds of seal meat and blubber at a meal, though I have read of ten to fifteen pounds being a not unusual consumption at one sitting. They eat but twice a day as a regular habit, before going to bed, and almost as soon as they awake. From my limited observation, I would say that an adult consumes about eight pounds of solid food a day, subject to variations according to the amount of exercise and the external temperature, the small quantities of tea, coffee, and flour consumed at a meal scarcely require mention as factors in the food supply.

The natives of the Danish stations have better facilities for procuring their food supply than the wandering tribes farther north; some of the former are provided with rifles, of an ancient pattern it is true, but as they deem it a long distance to shoot at more than twenty or thirty feet, their ingenuity is spent on getting within close range of their game, and they generally secure it, if they fire at all. Besides, they are provided with small skin boats or kyaks, which are very light, but of great strength, and can be transported with great facility over the ice to open water. These boats have the javelin or spear as part of the outfit, and the Eskimo from early youth is trained to manage the kyak and throw the spear, so that they become exceedingly expert, and it is seldom that the hunter goes out in season without returning with his game. The Eskimo, on s

Digitized by Google

a seal come to the surface for air, will, with a few strokes of the paddle, approach his kyak as near as possible; when the seal disappears beneath the surface a few quiet rapid strokes puts the kyak directly over the spot, then with his javelin poised he waits for the seal to reappear; should the head show itself above water within a distance of ten or fifteen feet, their aim is almost unerring. After the seal is struck, the head of the javelin is slipped off, and to it are attached about six fathoms of line, on to which a large bladder float is tied. The line and bladder are immediately cast into the water, and the seal carries them off until he is exhausted, then the line is hauled in and the seal at the end quietly dispatched with a small knife; not always quietly, however, for a large seal when wounded will often show fight, and wreck the kyak. The loss of life attending the hunt is quite considerable, as the frail skin boats are oftentimes cut through by the ice or swamped in rough water; the hands of the hunter are necessarily exposed, and many of them suffer from their being frozen during severe weather. They procure their fish by dexterously using a short line, and attaching a small ivory hook to it. They bob this up and down through a hole in the ice, and the unsuspecting fish that bite are thrown out on the ice; they have no system of netting.

The tribes to the north of the settlements, variously known as the Innuits, and called by Sir John Ross the Arctic Highlanders, are thrown entirely upon their own resources; their food supply is entirely animal in its nature, and their means of procuring it more restricted, as they do not possess either guns or kyaks, but simply a javelin tipped with ivory; they conceal themselves beside a hole in the ice where the seals come, and watch their opportunity of securing the game. Since Sir John Ross first described these people, they have been fast dying off, so that from several tribes numbering hundreds, they now scarcely number a hundred souls. The few seen by us represented men, women, and children, numbering twenty-five; they all wore long black matted hair streaming over their eyes and face, were well built physically, had greasy, shining, smiling faces, and seemed happy and contented; their articles of dress comprised but three garments, made of bear-skin, the rough untanned skin next to their own, a jumper or hood covered the body, short-legged pants from the hips to the knees, and boots made of bear-skin completed the outfit; in most instances the jumper and pants did not meet at the waist, so that an isthmus of naked skin for an inch or two was plainly visible; the same occurred at the meeting between the pants and boots; even though the temperature of the air was at the time +15°F., and sufficiently cold to me to make heavy clothes comfortable, they did not appear in the least distressed, and I have no doubt that exposed in the same way they endure temperatures below zero. In the coldest weather they wear thin under-garments made of the breasts of the eider duck.

The natives of the settlements procure, from the yearly visits of the Danish ship, cotton material with which they make their under-garments, so that the skin clothing does not come next to their bodies. The outer garments of the Eskimo in the settlements are made of the short-haired seal, and consist of but three pieces—hood, pants, and boots, with the cotton under-garments above mentioned.

We have now seen, in a general way, how these people procure their food, the nature of it, and the probable quantity consumed; how they dress, and the nature of the wearing apparel. The next inquiry is, how they live, or the general hygiene of their habitations.

In the settlements the abodes are permanent and fixed; they are constructed for the most part of stone and moss about five feet thick, the most pretentious having some woodwork about them in the shape of a door or a window, but most generally the approach to the interior of a hut is made through a narrow passage about four feet high, three feet broad, and five feet in length; through this one crawls, and at the end is found a hanging curtain of skin, which, on being pushed aside, admits you at once into the living room, which is a general kitchen, sitting-room, and bedroom for the occupants of the dwelling, who may number anywhere from six to twelve. The sleeping quarters are arranged along the sides of the room on raised platforms. The ventilation of the room is secured by the air coming in through the narrow passage and finding its way beyond the curtain, but this passage air is something beyond description in the way of odor, as the dogs generally collect in the passage for purposes of warmth, and the inmates of the household use it as a water-closet until the accumulations get troublesome from their quantity, and impede easy ingress and egress, when they are removed by the women. In many households the urine is collected, as it proves, after the ammoniacal fermentation takes place, an excellent detergent for cleansing the household cooking utensils. There is, fortunately, a hole in the roof of the dwelling, ostensibly to permit the egress of smoke, but as it is kept most sedulously stopped up most of the time it does not carry out its original design.

An ordinary dwelling possesses the following measurements: Height, eight feet, with a sloping oval roof; width, twelve feet; length, ten feet, which gives nearly 1000 cubic feet of air space. Were there no occupants at all in the rooms, the air would be highly objectionable, as there is but little chance for circulation; but with from six to twelve eating, sleeping, and performing other avocations of life; with the room filled with smoke from cooking seal meat and blubber, which also adds a very strong odor; with the smoke from the moss dipped in seal oil as a lamp; with the odor coming from the passage of filthy dogs and animal excreta, you get a combination that in point of impurity would be hard to equal; add to this the facts that they sleep in their clothing just as they have worn it during the day, and that general or even partial ablution is seldom or never indulged in, and the wonder is that they pass through infancy to childhood, to manhood, and in many instances to old age.

During the period of the year when the sun is above the horizon, their life is active and spent mostly outdoors. The men engage in the hunt; the women in preparing and dressing the skins, and making articles of wearing apparel. For the 115 to

Digitized by Google

120 days in winter when darkness prevails, thei lives become sedentary, and the hygienic surround ings, both personal and that of the habitation, ar at their worst.

With the purity of the cold as a germicide, epi demic disease seldom prevails amongst them. Rheu matism, pneumonia, and a species of influenza con tribute most largely to the death-rate. The Gov ernor of each district keeps a list of births and deaths but not much reliance can be placed on their diag nosis as to the cause of death. Scurvy has beer known amongst the natives, but only during winter when the food supply has been very scant.

With these few general preliminary remarks a bearing on the results of the observations, it struck me that it would be of interest to take the tempera ture of as many cases as possible, together with the pulse, and determine whether or not the food supply being hydro-carbonaceous and heat-producing, would counteract the extraneous surroundings of cold and great exposure on people who have passed their whole lives in these high latitudes. It had been my inten tion to pursue a series of thermometric observation on the crew of the ship, had we remained in the Arctic sufficiently long to have experienced very low temperatures, so as to see the results of a tem porary residence, but the shortness of the cruise pre vented that being done.

The following table is made up of the cases ob served, twenty-two at Disco, twelve at Upernivik, and three amongst the tribe that visited the ship off Wos tenholme Island, in latitude 77°. The observation were all made with the same thermometer, which was corrected before leaving the United States They were made in the forecastle house, which wa always kept warm by a large stove. The native were such as visited the ship out of curiosity, or to barter little articles. The thermometer was placed under the tongue and left there for five minutes.

Cases observed at Disco, Lat. 69°. *At Upernı*

21	Male.	25	68	98.2°		
22	Male.	35	66	98°		

From an analysis of the foregoing table it will be seen that the results show but little or no variation from the general physiological temperature. In but three cases was the temperature found to be below

Digitized by Google

our knowledge of liver and kidney disturbances, we know that an alkaline water has its share in producing disturbances of digestion, the result of which is the excessive production of lithic or uric acid, a fact sufficient to explain the frequency of uric acid concretions.

It is necessary to examine the food of these patients, as well as the climate in which they live, after making the statement positively that the water used by them is hard; that the river rushes swiftly through gorges cut in the limestone hills, hence it holds a large quantity of lime in solution, and this lime is not precipitated by boiling the water before using it to make the national drink "tea," but is simply made hot. We must bear in mind that foreigners living in this district for twenty, thirty, or forty years, do not develop the disease, and yet, while not a single case has occurred, they live under climatic conditions, which if they have anything to do with producing the disease, other things being equal, would produce it in them. The food of the foreigner is very different from that of the native, and he uses no water without boiling or filtering it. Not, however, with any idea that the water would produce the disease, but because the mountains from which drinking water is brought are used as burial places, the tillable land being too valuable for cemeteries. The light Bordeaux wines are used largely for drinking purposes by the foreigner, and I have no doubt his fear of drinking the essence of dead men prevents him from taking into his system one of the principal causes of stone through its effect upon the digestion.

The food, then, of the native is rice principally—so far, all right; but the animal food used is fish dried in the sun and salted—dried until it resembles leather, and is as hard as the nether millstone.

Next, vegetables treated in the same manner. Now he could scarcely take a diet more likely to tax his digestive powers to the utmost than this. Our patients are poorly nourished and suffer greatly from liver disease, a condition brought about by drinking hard water and eating such food as I have described, and a condition, according to Fothergill, "favorable to the abnormal formation of uric acid. The abundance of lithates in the urine when the liver is actively engaged in the process of digestion, renders it highly probable that certain peptones instead of undergoing further elaboration are turned aside and broken up prematurely into lithic acid. These lithates do not in any way represent tissue waste, for they have never been tissue. Just so the material which forms the uric acid might have been tissue under more favorable circumstances," but I may add, passing out through the kidneys, and in greater abundance than the urine can carry in solution, are deposited and give us our uric acid stones. So too, Dr. Henry Bennett says: "I have repeatedly alluded to the presence of morbid salts in the urine as a result of imperfect digestion," and in enumerating these salts he places those of uric acid first. Hence we find the drinking of hard water by patients afflicted with liver and kidney disturbances favors the production of stone but not necessarily an alkaline stone, for in these patients the chemical constituents of the food which are not digested, and which consequently do not become tissue, are much more likely to produce a stone, the formation of which will agree with the superabundant acid, generally uric. Now that I have attempted to show why we have uric acid stones when an alkaline water is used as a drink. I may further state that my observations lead me to conclude that the climate in which this hard water is used, and in which this indigestible food is eaten, bears no small share in favoring a condition of the system favorable to the production of stone. The southern part of China, at least the part from which our stone patients come, is an immense marsh. A clay soil produces fogs through its retentiveness of moisture, and marshes abound in exhalations unfavorable to health. These two conditions exist coupled with a warm, moist atmosphere. The north-east monsoon blowing from October to April is accompanied by almost constant rains in February, March, April, which rains continue in May, and the rainfall at Canton for these months, respectively, is on an average, 2.11, 3.43. 5, 3.03, inches. The velocity of the wind is between 4 and 8 miles per hour. The highest reading of the barometer is 30.25, and the lowest reading 29.90; while the thermometer registers 75° and 45°. It must be seen from this that the climate is moist and warm, and that both natives aud foreigners suffer from what we are now in the fashion of calling malaria. Now a malarial district, indigestible food, and hard water each have a share in giving us our sixty or seventy stone patients each year, and I think all observers will agree with me that a prevalence of this disorder in a district with well-defined boundaries where hard water is almost exclusively used, disproves the idea that hard water has no part in producing the disease, because in certain hard water districts no urinary calculi have been found, for in those districts no liver disturbance sufficient to the overproduction of uric acid has been noticed.

To come to that which is practical of vesical calculi—the operation for the removal of the stone. This was performed by me some two hundred times, and it may be of interest to notice our results in this far-off country. The condition of the patient when admitted to the hospital is, if we except his digestion, good. The opium smoking to which many of them are addicted (I do not speak now of opium sots, but of those who use a small quantity of the drug daily) does not seem to influence the results. In fact, I may say here that this habit receives a great deal of condemnation by anti-opium advocates, who, if they posted themselves upon the spot, would withdraw much of what they have said against it.

For the liver disorders of our patients we administer the usual remedy of a blue pill, and when the eye becomes clear, tongue clean, and the functions of the bowels well established, it matters little the condition of the urine—the patient is considered in good condition for operation. In children and young persons we always administer a large dose of santonine, with the result of the patient's passing large numbers of intestinal worms. How different this treatment from that practised by the native physician. The patient is dosed with nauseous compounds, oftentimes half a pint at a time, and, the

Digitized by Google

disease not yielding, the moxa is used, till losing faitl in the doctors of his own country he appplies to th foreign hospital.

Age seems to exercise a great influence upon th result of this operation. In the statistics of m report of the first 138 cases in which I operated find, out of 46, the number of those under 20 year of age, I lost but 2. Referring to these same statis tics, we have 25 between the ages of 20 and 30, witl 3 deaths; 16 between 30 and 40, with no deaths 35 between 40 and 50, with 2 deaths; 5 between 5 and 60, no deaths; and 9 between 60 and 70, with death: a total of 8 deaths in 138 or 1 death in 17¼ operations. This result was largely due to the fac that the Oriental sustains surgical operations muc better than the Anglo-Saxon. This is true of th Chinese, Japanese, and Malays, and in our hospital in the East it is a rare thing that we are called on t treat erysipelas, pyæmia, or tetanus, after operations yet we do not use the antiseptic method of Sir Josep Lister. If we did, perhaps our results might be better still I question if better results are obtained with it It would be simply an impossibility to make th Chinese appreciate such thorough cleanliness as i necessary to carry out this system. There seemed t be no particular season of the year when we obtaine better results than at others.

The hygienic surroundings of our Chinese patient are bad. Each patient brings his own bed and bed ding, and is generally accompanied by some membe of his family to cook for and nurse him. Thi custom was instituted when the hatred of the Chines toward the foreigner was so great as to make it hazardous undertaking to lose a patient in the hos pital, hence a relative was admitted with him to se that he was not disposed of in any irregular manner such, for instance, as killing him to obtain his eye for medicine, a popular belief amongst the Chinese This custom still prevails, although the cause for it n longer exists. This impromptu nurse is carefull watched by the regular nurses of the hospital. Thes latter have had no special training, do not speal English, and allow the patients to live while in th wards very much as when at home, with certain restric tions as to diet. The wards are built after the style o Chinese architecture—one story high, with sliding skylights, a window at one end, and a door at th other, in which we have cut large circular aperture which the patients cannot close. We are thus com pelled to place our ventilating apparatus beyond th reach of the patients, as the Chinaman like our negr has a penchant for closing a room he occupies ver tightly. The walls are of lime and are thoroughl whitewashed every month. I am particular to men tion these apparently insignificant points to show tha hospitals constructed on strictly hygienic principle are not necessary to give us good results where w have Chinese for patients.

These being the surroundings and the patient ir condition we operate by the usual lateral method. have adopted one or two departures in the operatio which, after a considerable experience I am con vinced are of value, and you will pardon me, there fore, if I consume enough of your time to speak o them. I am convinced that a small incision into th

Digitized by Google

which form around it through which the urine escapes, and it will never happen that the clots have to be removed to allow of the free escape of the urine—a thing which often does happen if no tube is used.

I regret that I am unable to give the proportion of those operated on who return for a second operation, another stone having formed, but I think it may safely be put at 1 in 70. Of course, the conditions exist which produced the first, but it is possible that the urethra, having been somewhat dilated by the passage of instruments when sounding for the stone, and the staff used at the time of the operation, may dilate the tube sufficiently to allow of the escape of a new stone when very small, which would have been retained had the urethra not been so dilated. For the performance of the second operation I have always made the incision into the perineum on the side opposite to that of the primary operation, to avoid the cicatrix as well as to cut the prostate in a new place. In this way I get quicker union and shun the adhesions between the rectum and prostate, which have resulted from the first operation.

TREATMENT OF DIABETES MELLITUS WITH CLEMENT'S SOLUTION OF ARSENITE OF BROMINE.

BY S. MAC SMITH, M.D.,
RESIDENT PHYSICIAN GERMANTOWN HOSPITAL, PHILADELPHIA.

JOHN S., aged 32 years, was admitted to the Germantown Hospital October 29, 1884, a pronounced case of diabetes mellitus; was sick six weeks previous to being admitted, at which time his domestic relations were such as to produce profound mental anxiety, which caused him to be delusive for several weeks, and when he applied for admission his spirits still remained much depressed, but he was rational and conversed intelligently; it should also be stated that there was possibly a hereditary predisposition to this disease, as the patient claimed his father suffered from a similar affection.

The patient's urine was examined and found to have a sp. gr. of 1.050, the amount voided in twenty-four hours being one hundred and three ounces, which readily responded to the several tests for sugar; the amount of sugar was not ascertained, but, as the urine contained very little urea, the high sp. gr. indicates a rather large percentage of sugar.

The patient was restricted to a nitrogenous diet, and placed on the several modes of treatment familiar to the profession, but without much, if any, improvement; his urine was frequently examined between October and the following April, and showed the sp. gr. to range from 1.040 to 1.050, the amount voided from eighty-five to one hundred ounces; he also became very much emaciated.

Some time in April we noticed, recommended by Dr. Austin Flint, Jr., the arsenite of bromine, "Clement's solution," for treatment of diabetes mellitus, and as all other agents had proven of no avail, we concluded to give this solution a trial, and report the following results: The drug was first administered in doses of three drops each ter in diem, increasing to five drops. After giving this solution for four days the urine was examined and found to have a sp. gr. of 1.018; amount voided in twenty-four hours, forty-two ounces; three days later the urine was again examined, sp. gr. 1.016, amount voided twenty-three ounces, in which condition it remained until the patient's death, of which a post-mortem showed the immediate cause to be phthisis pulmonalis.

Being encouraged by the above results, and rather predicting that something might be done for such unfortunate cases, we concluded to investigate still further the efficiency of this preparation, and therefore have, up to this present writing, seen nine cases treated in the manner above related with most happy results. Two of these cases were, as the one cited, quite chronic and subsequently died of phthisis pulmonalis, but the remaining seven of more recent development have increased in weight and assumed the responsibilities of life as in former years, and their urine is frequently examined with negative results; perhaps it would be presuming somewhat if we were to speak of these cases as being cured, for they may not have been under our notice long enough, but we can certainly join with Dr. Flint in recommending this preparation for trial at least, and possibly predict for it as being the future treatment of diabetes mellitus.

FRACTURE OF THE STERNAL END OF THE CLAVICLE

BY HAL C. WYMAN, M.D.,
SURGEON, WEST END DISPENSARY, DETROIT, MICH.

FRACTURE of the clavicle is of so common occurrence, that the humblest practitioner is familiar with it. The outer third or acromial end is the part of the bone most frequently broken; the middle third is less frequently the seat of fracture, and a fracture of the sternal end is so rare that I may be excused for describing the following case, which came under my observation through the kindness of Dr. J. E. Clark, of this city.

A robust boy, aged 16 years, was thrown from a wagon and severely injured. A large contused wound was made upon the left side of the head over the parietal eminence, and on the acromial aspect of the shoulder. When examined he complained of severe pain at the root of the neck. Crepitus was heard and felt about an inch from the sternal end of the left clavicle. There was a marked tendency for the sternal fragment of the clavicle to ride upward by the action of the sterno-mastoid muscle, the sharp broken surface pricking into the platysma, and causing spasm of that muscle. Treatment was embarrassed by this fact, and the result of the union was not as good as could have been desired. A very large callus formed because it was impossible to keep the fractured surfaces in apposition.

This callus bears such a relation to the long axis of the clavicle that when the left arm is thrown forward across the chest or backward over the back, a sharp angle of bone swings up and down at the root of the neck, making a very unsightly deformity, and inter-

4. The absolute maximum has been attained in cases of slow reproduction of the red corpuscles, and in which the corpuscles of Bizzozero attained the greatest dimension.

5. In two cases of chlorosis in which the number of red corpuscles was normal, there was absolute and relative increase of the corpuscles of Bizzozero.

6. In two cases of scorbutus these were increased, while the white corpuscles were reduced in number.

7. In two cases of pellagra, they were relatively and absolutely decreased.

8. In a case of extreme puerperal anæmia, two days before death the presence of nucleated red corpuscles was noted in the circulating blood.—*Rivista Internazionale di Medicina e Chirurgia*, September, 1885.

BISMUTH IN SURGICAL DRESSINGS.—MM. GOSSELIN and HÉRET, having experimented with bismuth as a surgical dressing, made a report concerning its efficacy at a recent meeting of the Académie des Sciences.

Subnitrate of bismuth was found useful in diminishing inflammation and arresting post-operative oozing of blood, and in promoting cicatrization without suppuration. The hæmostatic action of the bismuth is explained by the presence of a small quantity of nitric acid set free by the action of the water in which it is suspended.

Experience also shows the salt to possess antiseptic qualities, a fact which explains the absence of suppuration in wounds to which the dressing is applied.

The application of the salt in water in a proportion of 1 to 50 is recommended as preferable to sprinkling the powder directly upon the wound, and the application is made when oozing is not profuse.

MM. Gosselin and Héret call attention to the following practical points:

1. The subnitrate is preferable to the hydrate of bismuth, because the latter does possess the coagulating and constringing qualities due to the presence of the nitric acid in the former.

2. As to the method of application, whether in powder or suspended in water, the first possesses the advantage of more certainly producing the desired effects, but is inconvenient inasmuch as the bismuth is not absorbed but remains as a foreign body in intimate relation with the tissues, though suppuration is not thereby increased. If the salt is applied suspended in water, a proportion of 1 to 50 is preferable to that of 1 to 100.

3. The question whether sutures should be at once introduced, or whether the wound should remain open until the day succeeding the operation, is decided according to circumstances.

If hemorrhage is so profuse as to render probable accumulation of the salt in the wound, sutures should be introduced but the wound allowed to remain open until the following day, it in the meanwhile being covered with a dressing saturated with a mixture of bismuth and water (1 to 100) and compression bandages superimposed. A general rule is to close the wound as soon as drainage can be dispensed with.—*Revue de Thérapeutique*, October 1, 1885.

APOMORPHINE IN CROUP AND BRONCHITIS.—DR. STUTZ, of Neuminster, is loud in his praises of apomorphine, subcutaneously injected in diphtheria complicated with croup, and in primary croup itself. Of ten of these latter cases, he lost only one, and this he attributes to his not having been called in quickly enough. Similar treatment is also very valuable in dyspnœa due to bronchitis. He has also been successful in cases of arsenical poisoning in children; and in one where a woman had such severe pharyngitis that she was quite unable either to swallow or speak. An apomorphine injection quickly emptied the stomach of pus and mucus, and enabled her both to speak and swallow.—*The British Medical Journal*, Oct. 17, 1885.

AN ANTISEPTIC PESSARY.—At the recent meeting of the French Congress for the Advancement of Science, M. HAYHEM presented an antiseptic pessary. The instrument consisted of a Dumontpallier's pessary, mounted upon a hemisphere of caoutchouc and supplied with a tube of the same substance. The hemisphere contains a sponge, and the pessary is so applied that the cervix comes in contact with the sponge, which is saturated with a concentrated antiseptic fluid of boracic acid, or of corrosive sublimate in proportion of 1 to 2000.

The latter fluid was preferred by M. Hayhem as promoting cicatrization, and a rapid reproduction of the epithelium. Cleansing of the parts should be made twice daily, without removing the pessary.—*Revue de Thérapeutique*, October 1, 1885.

UMBILICAL HERNIA; RUPTURE; EXTRUSION OF SEVERAL FEET OF INTESTINE; DEATH.—DR. RENNIE records the following case in the *China Customs Medical Reports*, No. 28: It occurred in a native infant whose mother died of puerperal fever. When first seen on March 3, 1884, the child was 27 days old, and his illness was doubtless due to improper feeding. For some days he had been much troubled with flatulence, and cried a good deal. Since the evening of the 1st of March he had cried almost constantly, and on the following morning an umbilical hernia, about the size of an orange, was noticed. About 4 P. M. the coverings of the hernia burst, and the intestines commenced to pass out at the opening. On the evening of the 3d of March, he was enveloped in quilts, which the attendants said they had applied to keep the intestines warm. On removing the coverings it was found that the greater part of the small intestine had passed out of the abdominal cavity and, deeply congested, distended with gas, and smeared with a loose motion that had recently been passed, lay on the surface of the abdomen. After cleansing the parts with sponge and weak solution of carbolic acid in water, and removing some of the flatus by means of a small aspirator needle, the opening in the abdomen was enlarged (it was found impossible to return the bowel without doing so), the intestines replaced, and the wound stitched up with carbolized silk. Eight hours afterwards the child died.—*Medical Times*, Oct. 17, 1885.

TREATMENT OF HYDATID CYSTS OF THE LIVER BY CAPILLARY ELECTROLYSIS.—M. H. HENROT, at the Congress of Grenoble, discussing the modifications of the treatment of hydatid cysts of the liver which have occurred during the last few years, referred to the methods of simple capillary puncture, puncture and drainage by the large ovariotomy trocar, direct opening by the

Digitized by Google

covered his senses and intelligence, and until the pulse is easily counted.

6. The operation is entirely harmless.

7. Intravenous injection of artificial serum can only be considered as a means of producing reaction, but is without doubt the most powerful of all.

8. It is without effect upon the choleraic infection itself.

9. After its employment, as after that of all other methods to produce reaction, it is necessary to meet all indications as they arise.—*L'Union Médicale*, October 15, 1885.

THE THERAPEUTICS OF LEPROSY.—UNNA, *Monatshefte für prakt. Dermatologie*, from experience with a case of leprosy which he believes to have been cured, holds that:

1. Tubercular leprosy, even when generalized and extending over a period greater than one year, is curable.

2. Cure may be obtained in a relatively short period by energetic local and internal treatment.

3. The agents most useful in the treatment are sulpho-ichthyolate of ammonia, chrysophanic acid, pyrogallic acid, and resorcin.

4. The salts of the sulpho-ichthyolate of ammonia should be employed externally in concentrated solution. Internally, fifteen grains daily are sufficient, their action is efficacious in visceral leprosy. Externally, these preparations are valuable in debilitated patients with a very sensitive skin when more energetic agents cannot be employed, or when these have already irritated the skin.

5. Resorcin in ointment in a strength of twenty per cent., is a valuable remedy in the treatment of the disease.

6. Pyrogallic acid applied to the skin in ointment (five per cent.), or as a plaster, also gives good results.

7. Chrysophanic acid of a strength of ten per cent. is perhaps the best remedy with which to combat the disease. To avoid its introduction into the eyes, application should not be made upon the hands or face.

It may be employed along with other remedies.—*Revue des Sciences Médicales*, October, 1885.

THE FORMULA FOR A SAFE AND PRACTICAL GENERAL ANÆSTHETIC.—DR. B. W. RICHARDSON enumerates the requirements of a safe anæsthetic as follows:

1. It must be a fluid. Gases, however good, are not practicable as agents for general and ready use; and, as at the temperature of the blood they remain as gases, they exert, when dissolved in blood, no action from change of state within the organism. To narcotize with them it is, consequently, necessary to give them in large quantities—it may be even to the exclusion of air altogether. The influence of a gas thus administered is of necessity limited to the briefest interval of time; steady continuance would lead to death from asphyxia.

2. The fluid must possess homogeny and stability. Mixtures of different fluids are unreliable. Fluids which easily decompose under the influence of heat or of light are unreliable.

3. The fluid must be of pleasant odor, and must produce no local irritation when brought into contact with any surface. All the fluids which, like chloroform, amylene, and turpentine, cause redness and irritation of surface, cause also, when introduced through the blood, irritability of muscle and rigidity, together with vomiting.

4. The boiling-point of the fluid should be not less than 110° and not over 130° Fahr. A fluid which should have a boiling-point 20° Fahr. above the body, and other properties equally good to commend it, would be convenient in every respect It could be easily preserved, and as an anæsthetic it would be alike applicable to long and short operations.

5. The density of the vapor of the fluid should be about 40, taking hydrogen as unity.

6. The last, and perhaps almost the essential quality, relates to the solubility of the vapor in the blood. Up to the present time insufficient attention has been paid to this important point. Ether is too soluble, chloroform too insoluble. The mean between these two would be nearest to the requirement.

In brief, the agent wanted is a stable fluid; the oxide of a radical of the methene, ethene, or propene series, or of some similar hydrocarbon base, having a boiling-point of 50° C. (122° Fahr.), a vapor density of 40°, a solubility in blood of one part in fifty, at 37° C. (99° Fahr.), and yielding an unirritating agreeable vapor for inhalation.—*The Asclepiad*, October, 1885.

HÆMOSTATIC PILLS.—HUCHARD recommends the following:

℞.—Ergotine,
Quiniæ sulph. . . . . āā gr. xxx.
Digitalis pulv.,
Ext. hyoscyam. . . . . āā gr. iij.—M.
Ft. pil. No. xx.

S. Five to eight pills daily in the various forms of hemorrhage.—*L'Union Médicale*, October 13, 1885.

THE RELATIONS OF EPILEPSY AND HEMICRANIA.—MÖBIUS, in a discussion of the etiology of hemicrania, refutes the generally received opinion that hemicrania is of sympathetic origin, because of the well-known fact that diseases of this nerve, paralysis or irritation, are never accompanied with pain; and while not considering it as yet established whether the disease is neuralgic or vaso-motor in its origin, he allies it with epilepsy, and bases his conclusions upon the following facts:

1. Both diseases may originate from organic lesions of the brain, from reflex causes, or be presented as neuroses *per se*.

2. Both diseases are for the most part congenital and hereditary.

3. Both explode rapidly at periods widely separated, or the reverse.

4. Both diseases present prodromata of their attack.

5. As the epileptic attack may be typical or present its special features only in part, or be substituted by a complex of foreign symptoms, so in hemicrania at times scotoma only may supervene, while again only its equivalents, such as general malaise, weakness, nausea, may occur.

6. At times the attacks in hemicrania, as in epilepsy, are frequent, while again there is a true *status hemicranius*, analogous to the *status epilepticus*.

7. Both diseases are incurable and epilepsy of reflex

Digitized by Google

origin disappears with the removal of the cause; the same occurs in hemicrania, as is shown by facts lately published.

8. As to the location of the lesion in these diseases, while it is generally accepted that in epilepsy the seat is cortical, Möbius inclines to the opinion that in hemicrania the effects are due to irritation of the descending root of the trigeminus, in the region where the fibres separate to supply the dura mater.—*Rivista Internazionale di Medicina e Chirurgia*, September, 1885.

Peptonuria and the Physiology of the Peptones.—Max Wassermann, *Thèse de Paris*, 1885, finds that:

1. Peptone is found in the urine in certain diseases, most frequently in such as are complicated with suppuration, or in which there are formed collections of some plastic substance.

2. Peptonuria appears to be constant in suppurating osteitis.

3. Peptonuria is caused by the destruction of the leucocytes, and its existence permits the diagnosis of suppuration or the regression of a plastic exudate.

4. Peptones introduced into the economy by other channels than the intestinal tract, are eliminated by the urine.

5. Peptones do not exist in the normal blood and do not traverse the intestinal walls unless converted into albumen.

6. It appears that the peptones are not directly assimilable, and hence the fact of their elimination by the urine after introduction into the blood by any other channel than the intestinal tract, such as by absorption from suppurating foci.—*Revue des Sciences Médicales*, October, 1885.

Treatment of Cardiac Hæmoptysis.—M. Germain Sée, in the treatment of cardiac hæmoptysis, recommends the use of the aqueous extract of ergot, in doses of sixty to seventy-five grains in twenty-four hours, combined with a grain and a half to two and a fourth of opium.

Hypodermic injections of ergotine may also be used when not resulting in abscess. The use of turpentine in syrups or capsules also is advantageous, but most reliance is to be placed upon toning up the heart by the use of digitalis.—*L'Union Médicale*, October 15, 1885.

Infectious Malignant Periostitis.—Dr. Andrea Ceccherelli in a clinical and experimental study of infectious malignant periostitis, after reference to the literature of the condition described under this term, makes the following résumé of the points to be observed in its treatment:

1. In malignant infectious periostitis in view of the serious nature of the disease, deep incisions should at once be made, by which the bone may be preserved when there is doubt whether its substance proper is diseased. Drainage should also be established, and the wound repeatedly washed with sulphocarbolate of zinc, carbolic acid, or chloride of zinc.

2. Trephining should be performed early. In order certainly to reach the track of the suppuration, the trephine, should be applied in several localities. The bone should also be scraped, and in cases of extreme extension of the disease resection should be practised.

3. Amputation should not be resorted to until by reason of the existence of diffuse inflammation and abscess of the bone, as shown by profuse suppuration, the general, together with the local symptoms, are most serious.

4. The use of tonics and antiseptics should be at once instituted, and all complications combated.—*Lo Sperimentale*, August, 1885.

Total Absence of the Vagina; Menstrual Retention During Two Years, Followed by Operation and Cure.—Eastman reports the case of a girl fifteen years of age who for two years experienced periodic pain in the pelvis, which each month increased in violence, finally becoming constant and accompanied with much discomfort during defecation.

The right iliac region was occupied by a tumor, gourd-like in form, and while the external genitals were normal, no trace of a vagina was discoverable.

The patient being anæsthetized, the uterus and Fallopian tubes were found distended with retained menstrual fluid.

Introducing a finger into the rectum and a sound entrusted to an assistant into the bladder, Dr. Eastman made an incision sufficient for the admission of his finger and then, aided by the handle of a bistoury, tore the tissues until the uterus was reached. This organ was then punctured and more than two quarts of retained fluid escaped.

In order to prevent the irrigating fluid from entering the abdominal cavity through the Fallopian tubes, a double canula was used.

Though puncture had been made through the uterine wall, the os uteri was discovered later, and drainage established through it.

A Sims's vaginal dilator was used to prevent closure of the vagina. In the progress of the case toward recovery, nothing abnormal occurred until six weeks subsequent to the operation, when the patient complained of intense pain. It was found that atresia of the cervix had occurred, which on dilatation permitted the escape of more than a quart of pus. From this time on the patient menstruated regularly, and permanent establishment of the menstrual function seems assured.—*Archives de Tocologie*, October, 1885.

Peritomy for Granular Lids.—Mr. Spencer Watson exhibited at a recent meeting of the Ophthalmological Society of the United Kingdom a case of granular lids and rough vascular corneæ treated by peritomy, with partially successful results. The patient was a woman, aged 22. The right eye was operated on in May, and the left in July last. The improvement was but partial in both eyes, the corneæ having become somewhat clearer and less vascular, but the palpebral mucous membrane remained as rough and granular as before the operations.

Mr. Anderson Critchett thought that Mr. Watson had exaggerated the late Mr. G. Critchett's opinion, which was that, in many cases, peritomy sufficed without other treatment; in others, it was necessary to treat the granulations after peritomy. If a considerable power of constitutional repair were present, then the tight cicatrix necessary for the complete cure would be formed, but this frequently failed to occur in strumous

Digitized by Google

subjects. No doubt, in some cases, the treatment by jequirity is sufficient.

MR. NETTLESHIP said that, in his experience, peritomy had, in a certain proportion of cases, given most brilliant results. In one case in which he had freely used jequirity, the subsequent performance of peritomy was followed by a most satisfactory result, the corneæ becoming almost perfectly clear.—*British Med. Journal*, October 24, 1885.

ARSENIC IN THE TREATMENT OF CHOREA.—At a meeting of the Harveian Society, held October 15, 1885, DR. W. B. CHEADLE, speaking from the careful notes, of 160 cases of chorea observed during the period of eight years, stated that the average duration of the disease, under treatment, had been five weeks (the extremes being ten weeks and four days); whereas cases without treatment may extend from eleven to fifty-two weeks, or indefinitely. The author had tried various methods, including rest and expectancy, with results sometimes beneficial, but never completely successful. In arsenic, he had at last found an agent which did succeed. Todd, as long as forty years ago, had recognized its power; so had Babington and Begbie: but dread of the poison had checked their use of the remedy. Dr. Cheadle narrated some striking cases of rapid improvement under the influence of ordinary doses of liquor arsenicalis, with small doses of tincture of perchloride of iron. A comparison of a long series of cases treated without arsenic and with arsenic, respectively, gave for the former an average duration of forty days; for the latter, twenty-nine days; and this difference was increased when the last fifty-eight cases were compared with fifty-eight consecutive cases in the former series, the average duration under arsenic being only twenty-four days. Arsenic was in every case well borne, excepting a remarkable result repeatedly observed by the author, but not hitherto described by others; namely, a bronzing of the skin analogous to that observed in Addison's disease. The staining was most marked in the flexures, did not affect the face, and ultimately disappeared. In one case, however, it had become permanent, but would probably vanish in time. The pigment deposited was not metallic, as in discoloration by silver, but resembled the pigmentation due to chronic congestion. In conclusion, whilst advocating arsenic in chorea, the author did not wish to depreciate the value of other therapeutic agents, which should be employed concurrently.—*British Med. Journal*, October 24, 1885.

DERMATOSES CONSECUTIVE AND ANTECEDENT TO RENAL DISEASE.—DR. GEORGES THIBIERGE, in an exhaustive discussion of the relation of dermatoses with diseases of kidney and with albuminuria, clearly shows that certain forms of nephritis may accompany or follow certain forms of skin disease. Examining the three principal theories by which it is attempted to explain the presence of albumen in the urine under these conditions, namely:

1. That albumen is due to the suppression of the cutaneous functions, especially that of perspiration.

2. That it results from disturbance of the renal circulation, produced by the irritation which the cutaneous lesions excite in the terminal nerve fibres.

3. That it is excited by an infectious nephritis consecutive to the introduction into the blood current of microörganisms originating in the cutaneous lesions;—he dismisses the first theory as inapplicable to human pathology, and while it is admitted that for some cases in which the albuminaria is slight and transient the second theory is sufficient explanation, it is to the third as supported by the great number of cases in which the renal disturbance occurs, and in which it first disappears only when the skin disease is cured, that the author unhesitatingly subscribes.

Dr. Thibierge next considers skin diseases as consecutive upon renal disease.

Various forms of skin disease, among which are pruritus, roseola, purpura, pustular eruptions, etc., are discussed under this head, and the author concludes that although their origin is probably of uræmic nature, this cannot be affirmed without reserve.

The study of Dr. Thibierge is extremely interesting, as showing the complexity of the relations existing between cutaneous disease and nephritis, the author proving that each may follow or precede the other as cause or consequence, and that they mutually may react and aggravate each other.—*Annales de Dermatologie et de Syphiligraphie*, August and September, 1885.

THE ACTION OF THE IODIDES UPON GENERAL NUTRITION, AND THEIR METHOD OF ELIMINATION.—DR. DUCHESNE (Thèse de Paris, 1885), in a study of the action of the various iodides, holds that it is impossible to consider the iodides as a unit, either as accelerators or moderators of nutrition, inasmuch as some, as metallic iodine and the iodide of potassium, hasten the disintegration of nitrogenized matter, while others, as the iodides of sodium and calcium, retard it. There is accordingly no equivalence of action among these different agents, neither as relates to intensity or mode of operation. According to the form in which iodine is introduced into the economy, whether as the metalloid or combined with potassium, effects different both in intensity and nature are obtained.

Further, the general effects of the drug are influenced by the condition of the kidneys and the constitution of the patient.

As a general rule, when it is desired to influence nutrition for the relief of such diseases as gout or chronic rheumatism, metallic iodine is to be preferred.

According to Dr. Duchesne, the iodides of potassium and sodium increase, while the iodide of calcium decreases, nutrition.

The iodides of potassium, sodium, calcium, and ammonium increase the production of uric acid, while the tincture of iodine diminishes it.

The elimination of phosphoric acid is diminished by the iodides of sodium and calcium and increased by the iodide of ammonium and tincture of iodine. Under the action of the iodide of potassium it may be increased or diminished.

The iodides of potassium and calcium decrease the elimination of the chlorides, the iodides of ammonium and the tincture of iodine increase their elimination, while the polyiodides appear indifferent. The rapidity with which iodine is eliminated by the urine is not so great as represented by some authorities.—*Revue Médicale*, September, 1885.

disease are most diverse, depending largely upon the organs affected. When localized in the jaws or neck, there is a reasonable hope of effecting a cure with the knife, but when it is deep seated, and has produced metastasis, treatment is unavailing. The disease occurs extensively among cattle in this country, and two cases have recently been reported from Chicago. Others will doubtless be detected when the attention of surgeons is directed to the subject. The presence of the yellow actinomyces granules in the pus may be taken as pathognomonic of the existence of the disease.

DISTENTION OF THE RECTUM AND SUPRAPUBIC LITHOTOMY.

Since the time when suprapubic lithotomy was first practised, more than three hundred years ago, nothing has contributed so much to the favor with which it is now regarded as the invention of that step in its *technique* which is known as Petersen's method. This method consists, as many of our readers are aware, in forcing the bladder out of the true pelvis, and elevating the fold of peritoneum which usually comes down in front of it, almost, or quite, to the level of the symphysis pubis, by distending the rectum and bladder.

The first suggestion of this plan is usually attributed to Prof. Petersen, of Kiel, who, in a paper read before the Ninth Congress of the Deutsche Gesellschaft für Chirurgie, on April 7, 1880, gave an account of some experiments which he had conducted to demonstrate the effect of such a practice, and of two operations in which he had resorted to it with entire success, on the strength of which he urged its adoption as a general method. The originality of this idea of Prof. Petersen was not questioned at that time, and the few surgeons who discussed his paper seemed to think that neither it nor the suprapubic operation was worthy of adoption. Yet, only two years before, the very same body had listened to a communication from Prof. Braune, of Leipzig, who reported the results of some experiments which had been made, under his direction, by Dr. Garson, of Edinburgh, at that time studying with him, the object of which was to determine the effect upon the contents of the pelvis of the distention caused by introducing the hand into the rectum for the purpose of exploration, as suggested and practised by Simon.

The bearing of these experiments on the subject of suprapubic lithotomy seems not to have been observed by Prof. Braune, or by his hearers—unless Prof. Petersen was among them. But it was not overlooked in the paper giving an account of them which Dr. Garson himself published in the *Edinburgh Medical Journal*, in October, 1878; for here it is distinctly stated: "It is evident that in performing the suprapubic operation for lithotomy or puncture of the bladder that viscus can be as easily raised above the symphysis by distending the rectum as by injecting the bladder, and that in cases where it is not advisable to distend the bladder to a large size, distention of the rectum is all that is required to make the parts suitable for the operation." Nevertheless, although this sounds like the plan of Petersen, it will be noticed that it is not identical with it. Dr. Garson, while he learned from his experiments that it is solely by the distention of the rectum that the peritoneum is carried up from the symphysis pubis, suggests this procedure only as a substitute for distention of the bladder, with the sole object of raising the bladder, and not the peritoneum, above the pubes, and this only in cases in which it is not advisable to distend the viscus to a large size. Petersen, on the contrary, proposed his method as an essential part of every operation of suprapubic lithotomy, and for the distinct purpose of raising the peritoneum, after becoming convinced of its value by direct experimentation, and also by the result of two operations conducted in this way. Hence, it is clear that whatever merit attaches to this method belongs of right to Prof. Petersen; for, although he did not appreciate as justly as did Dr. Garson the relative parts played by the distention of the rectum and that of the bladder in this method, yet, his practical application of it, meeting with success at his own hands, has been imitated almost wherever the suprapubic lithotomy has been performed since 1880, and Petersen's method is now usually regarded as an integral part of the operation.

The most recent contribution to the literature of this subject is a valuable paper by DR. FEHLEISEN, of Berlin, "Ueber die Verschiebung der Harnblase bei der Tamponnade des Rectum," which appeared in Langenbeck's *Archiv für klinische Chirurgie*, Bd. xxxii. Heft 3, and in which can be found all that is needed to complete our understanding of the mechanism of this method, and to indicate what is the best way of carrying it out. Dr. Fehleisen's paper is illustrated by four large colored lithographs, each of which represents vertical sections of a body frozen after various injections of the rectum and bladder had been practised.

One of the plates shows the bladder distended with about 9½ ounces of fluid. Here the bladder is round, and, while it presents a surface several centimetres long above the level of the pubes, it is still covered in front by the peritoneum. The next plate shows the effect of distention of the bladder with only about 6 ounces, combined with distention of the rectum with about 15 ounces. Here the section of the bladder is more or less pentagonal—a shape which is due chiefly to the forcing forwards of its posterior wall by the distention of the rectum behind it—and the peritoneum has been pressed up so that it leaves

Digitized by Google

a clear space above the pubes about one inch and a half long. A third plate shows the result of an experiment intended to determine what share in the displacement of the peritoneum is to be attributed to the filling of the rectum—a point which Dr. Garson had previously investigated. The bladder was injected with as much fluid as both it and the rectum contained in the preceding experiment. Here we find, again, an almost round bladder, with the peritoneum descending in front of it, to within four-fifths of an inch of the pubes. The last plate shows the effect of filling both bladder and rectum with considerable quantities of fluid. Here the bladder contains about 13 ounces, and the rectum about 16 ounces, and the peritoneum is removed from the symphysis pubis to a distance of about 3¼ inches.

The demonstration of these experiments is complete, and there can be little doubt that Dr. Fehleisen suggests in his paper the best way to carry out the suggestions of Dr. Garson and Prof. Petersen, in recommending that, as preliminary to the cutting part of the operation of suprapubic lithotomy, the rectum of an adult shall be distended with from 14 to 16 ounces of fluid, and then the bladder injected with from 8 to 10 ounces, or exceptionally with 13½ ounces of fluid. The essential point in this way of conducting the distention, it will be seen, is that the rectum shall contain more fluid than the bladder. An incidental advantage of this method consists in the pressing forward of the fundus of the bladder, which facilitates examination of it, or operation upon it, in cases of tumor of the viscus.

But one thing remains to be mentioned in connection with this paper, and that is, that the writer suggests, instead of the use of a colpeurynter introduced into the rectum, that the distention be effected by introducing an œsophageal tube, over the end of which a condom has been slipped, and attached to the tube at a distance of three to four inches from the point. This is to be distended by injecting water through the tube, after it has been passed all the way up the promontory of the sacrum. The injection of the bladder can be effected through a catheter previously introduced.

The great merit of Petersen's method is that it removes what has always been a source of anxiety to those who are not very familiar with the history and statistics of suprapubic lithotomy. The fact is, that these precautions are not essential to a successful performance of the operation, and that wounding the peritoneum has been a very rare occurrence, even when the operation was done in the simplest and most informal manner. Dr. Dulles, who has made this operation the subject of continued study during the ten years which have elapsed since he published an analysis of 480 cases in *The American Journal of the Medical Sciences*, July, 1875, states that he has now collated about 750 cases, and that out of nearly 650 operations practised before Petersen's method was suggested, in only 19 was the peritoneum cut or burst, 1 of these cuttings being intentional, and that of the 19 patients, 11 recovered. It appears, indeed, from a study of a very large number of cases, that it is not difficult to avoid the peritoneum if due care be exercised. Nevertheless, we would recommend the adoption of the method of distending the rectum suggested by Garson and Petersen, and improved upon by Fehleisen, as encouraging those who are less sure than we are that it is not essential to safety. With it, and with after-treatment by drainage, or by suturing the bladder, where this can be properly done, as indicated in our issue of September 12, last, the suprapubic operation offers a fine field for the enterprise of American, as well as of other surgeons.

THE MASSACHUSETTS EMERGENCY AND HYGIENE ASSOCIATION.

THERE is no more wholesome indication abroad in the realm of public hygiene than the wide and practical interest taken in this all-important subject by the non-professional public. Individuals have, for a long time, been noted for their self-sacrificing labors in this direction; but of late, influential associations have been formed for the prosecution of the work on a broader basis than that of personal effort and for compelling a hearing, as can be done by an earnest body of prominent citizens so much better than when a single voice is crying in the wilderness. The excellent work done by the Manchester and Salford Society in England, and by the lectures on emergencies and nursing in New York and in this city under the auspices of the charity organizations, the county medical, and similar societies, is proof of the recognition of the need of the hour, and of the value of united effort. No effort of theirs, however, is more comprehensive and far-reaching than that of the Association, the name of which heads this article.

In 1883 the Women's Educational Society, a voluntary body of active, unselfish women, began courses of lectures, seven of which were free, and three to paying classes. The next year the number went up with a leap to twenty-five. It was then seen that the work was becoming so large and important, that the old Society gave way to a new and broader one—The Massachusetts Emergency and Hygiene Association. This Society has planned a splendidly useful work on a broad scale. It proposes to form branches throughout the State; to give instruction to those who can pay a fee; to give free lectures to railroad employés, mill operatives, stevedores, and the like; to the police, the militia, and the fire department; to missions and public institutions, and to teachers and the more advanced pupils in normal schools,

Digitized by Google

and such others as may be interested in the public health. It speaks well for the intelligence of the community, for the unselfishness of the promoters of the schemes, and for the generosity of the instructors, that such a broad purpose should be entertained, and has been successfully initiated.

Their first publication, as we judge it to be, consists of *Six Lectures upon School Hygiene*, forming a book of 200 pages, the contents of which are most agreeable and instructive reading. As a book it is valuable, but far beyond this value is the interest it has already awakened among the very class it is intended to reach. As lectures delivered to teachers, the addresses must have carried weight and given an impetus to school hygiene, that no mere book issued to an absorbed and inattentive public could possibly do.

Dr. Frank Wells, Vice-President of the Association, opens the book in an address on the general subject of school hygiene, and later gives another on drainage. Dr. F. W. Draper's lecture is on heating and ventilation; Dr. C. H. Williams's on the use and care of the eyes; Dr. G. B. Shattuck's on epidemics and disinfection; and Dr. C. F. Folsom's on the relation of the public schools to disorders of the nervous system.

The book should be read by every school-teacher in the land, for it will not only give information, but will stimulate every such reader to a higher and better aim as a teacher to develop and care for both mind and body—the body as a necessary factor in mental growth. Dr. Folsom, we think, has been especially happy in a nice discrimination as to the question of over-work, particularly in girls, balancing with judicial skill the assertions on both sides of this much vexed question.

Other cities than Boston may well imitate such powerful voluntary associations, and convert what is now useful but desultory work into a systematized effort of the greatest value and power.

IMPERFORATION, AND SUBSEQUENT GREAT DISTENSIBILITY OF THE HYMEN.

IN the *Revue Medicale* for October 10th, an interesting case of congenital atresia of the hymen, with subsequent great dilatability of this membrane, is given.

The subject was twenty-four years of age, married, but childless. When fourteen years of age the manifestations of the change from girlhood to womanhood occurred, except that the monthly flow failed, though there was at regular periods a decided menstrual molimen. A hypogastric tumor was manifest, increasing somewhat at each menstrual effort, but diminishing slightly in the intervals. The symptoms continued until she was twenty-one years old, when the abdominal tumor had increased until it equalled in size that of pregnancy at term. A puncture was made in the hymen, and the blood accumulated in the uterus and vagina was discharged, with entire disappearance of the abdominal tumor.

It is worthy of remark that there was a notable tolerance of accumulated menstrual fluid shown in this case. It is not unusual, as pointed out by Bernutz, for a fatal result to occur in the second or in the third year after the beginning of the menstrual efforts. This fatal result is caused by a general peritonitis excited by a portion of the collected fluid passing through the oviducts into the peritoneal cavity. Nevertheless, though in this case menstrual collection continued for seven years without this very dangerous accident occurring, Hervez de Chégoin, according to Bernutz, has reported one in which ten years elapsed. But such long delay as occurred even in the first case is not to be expected, and hence a temporizing practice is utterly forbidden.

Another interesting fact in connection with the case is the safe result from a simple puncture of the hymeneal membrane. While some advocate such puncture, with gradual evacuation of the menstrual accumulation, others, foremost among whom is Emmet, advise free incision with thorough washing out of the uterine cavity; it is important, therefore, to know the result of one or of the other method of operating, that when a sufficient number of facts is collected we may adopt that practice which has been proved the safer.

Shortly after the operation above stated the subject married, but was childless. As there was no obstacle to coition, as digital examination was readily made, and as a speculum could be easily introduced, it seemed improbable that the sterility which was found to exist was due to any mechanical obstacle. But vaginal examination with the finger was unsatisfactory in this, that the cervix could not be directly touched, for there seemed to be a thin membrane intervening between it and the finger. This membrane proved to be the hymen, which furnished a complete covering to the finger as it was pressed toward the vaginal vault. Doubtless such remarkable stretching of the hymen had been rendered possible by continued copulation, the result having been gradually attained. Excision of the hymen was followed by fecundity.

REVIEWS.

HOW TO DRAIN A HOUSE. PRACTICAL INFORMATION FOR HOUSEHOLDERS. By DR. GEORGE E. WARING, JR., M. Inst. C. E., Consulting Engineer for Sanitary Drainage. 12mo. pp. 222. New York: Henry Holt & Co., 1885.

THE author of this timely little book commences his preface with the statement that drains in modern houses are probably the most serious enemies with which struggling humanity has to contend, but that they are never

cases of clubfoot are the result of infantile palsy. Deformities of the upper extremities are rare; this disease differing in this respect from cerebral palsies. The exact causes of infantile palsy are unknown. Overfatigue often precedes an attack; sudden chilling is considered by Seguin to be a frequent cause.

The *prognosis* as to perfect recovery is only moderately good. In many cases the most faithful treatment fails to restore the paralyzed muscles, but in almost every case we can expect more or less improvement.

In the early stages of the paralysis after the subsidence of the fever, the treatment should consist of mild stimulation to the spine; ergot and small doses of bromide of potassium should be given internally. Later in the disease, iodide of potassium should be given instead of the bromide. When the palsy is established, electricity and massage are the means to be depended upon. They must be persisted in for months or even for years. Internal treatment is of little or no value, unless there is some failure in the general health of the child.

Spasmodic paralysis, as seen in children, is of two varieties: when of primary spinal origin, or when there is a descending degeneration of the cord from a primary cerebral lesion. Sometimes there seems to be a congenital defect in the motor tracts of both brain and cord. In the spinal variety, there is often seen, soon after birth, rigidity of the limbs, at first this is only occasional, but, as the child gets older, every effort to move a limb causes muscular rigidity in it. The child does not attempt to walk until three or four years of age. Then, when it is supported under the arms and it tries to stand or to walk, the movements are very peculiar and characteristic. The feet are extended and inverted, so that the child rests on the toes. The knees are strongly adducted and lock together, so that the legs become entangled. By degrees the child becomes able to walk with the aid of apparatus or some form of crutch. The hands and arms are often affected, and every effort causes muscular rigidity to come on. The mind is unaffected in these cases and the speech may be distinct although it is often very defective. Sensation is unimpaired, and the patella reflex and ankle clonus are exaggerated. There is no wasting of the muscles. By these symptoms we infer that the disease is localized in the lateral columns; but exactly what is the nature of the lesions we do not know, for no post-mortem examinations have been made in these cases. The cause is unknown. Hamilton found three of seven cases which he had collected were premature births, Adherent and contracted prepuce have been thought by some to be caused by reflex influence of the spasmodic paralysis, but operation has not given relief. The treatment should consist of massage, galvanism to the spine, ergot, and cod-liver oil. Fluid extract of conium may be given to allay spasm. In some cases great improvement follows this treatment.

Even when we can do no positive good to the limbs, very much can be effected by the aid of apparatus. Properly adjusted braces to the legs will enable the child to walk on crutches or in a Darrach wheel-crutch.

There is a form of spasmodic spinal paralysis in which the child is imbecile. In these cases there has probably been congenital defect in cerebral development. The head is small and there is no evidence of intellect, often nystagmus is present.

Paralysis from Pott's Disease.—Paralysis of the lower extremities may result from caries of the spine. The lesion may be either a meningitis or a myelitis. If meningitis alone, there are considerable pain and contraction of the legs. Generally there is a transverse myelitis. The symptoms are numbness and pricking of the legs with loss of sensation, gradually increasing loss of power with wasting of the muscles, incontinence of feces with retention or incontinence of urine. Sometimes there are ulcers over the sacrum or on the limbs.

The indications for treatment are evident. An apparatus which will take the weight of the body from the spine is necessary, and is sometimes sufficient of itself. Frequently, however, the application of the actual cautery over the spine brings improvement in the symptoms when apparatus has done no good. Massage and electricity should be used to restore the atrophied muscles.

Paralysis from rachitis and diphtheria is seldom complete. The former is often spoken of as the pseudo palsy of rickets. Negro children, who are very subject to rachitis in cities, often have rachitic paralysis. The child at three or four years is unable to walk or stand. Sometimes it has not sufficient muscular development to sit upright. It can move every limb and has no loss of sensation, but has no power. Cod-liver oil and massage bring about the most satisfactory results in these cases.

Diphtheritic paralysis usually begins in the muscles of the soft palate and pharynx, and extends to the extremities. It is generally bilateral and incomplete, but I have seen a case in which it was hemiplegic. It is considered peripheral in character and is believed by some to be connected with the altered condition of the blood consequent on the original attack. Diphtheritic paralysis is rarely fatal and lasts in most cases only a few weeks, although it may continue for months. Strychnia and electricity are the means to be employed, and the case usually responds promptly to these remedies.

Pseudo-hypertrophic paralysis is a rare affection, but is of much interest. The disease belongs almost exclusively to infancy. It is characterized by muscular paralysis with great increase in the bulk of the muscles. This enlargement is due to fatty deposits, while the muscular tissue proper is atrophied. The affection begins with weakness of the legs, a peculiar balancing of the trunk and separation of the legs in walking. The shoulders are thrown far back in standing and walking. There is great difficulty in getting from the sitting to a standing position. Later in the disease the muscles become wasted and shrunken, and the general health begins to suffer. Death results from implication of the respiratory muscles. The skin is mottled like a piece of castile soap. The tendon reflexes are abolished and electro-muscular contractility is impaired. There is often a greater or less amount of mental weakness. There is no loss of power over the bladder and rectum, and sensation is not affected. Heredity influences the disease, which is slow in its progress, but the course is steadily downward.

Friedreich's disease is still more rare than the pre-

Digitized by Google

ceding. It is practically locomotor ataxia in childhood. There is evidenced here also a hereditary predisposition, and the female children seem most liable.

Cerebral Palsies.—Hemiplegia may result from some injury at the time of birth, either from the forceps or from the pressure of a prolonged labor. A child may be born hemiplegic after a perfectly natural and easy labor. Under these circumstances we must regard the paralysis as the result of imperfect cerebral development. Hemiplegia under these circumstances is generally permanent. The side affected grows less rapidly than the other. The flexors of the arm and hand are usually contracted. The leg becomes rigid in the act of walking.

Convulsion is almost always associated with cerebral paralysis, either immediately preceding the attack or occurring soon after. The convulsive movements are most violent on the side which is subsequently paralyzed. The child will have an idiotic expression and speak indistinctly, but its friends think it intelligent. The convulsions are liable to return when the child is older, and then assume an epileptic form. The walk is peculiar and is called the *spastic* gait. The patient plods along looking as if he were about to pitch forward. The affected limbs are smaller and shorter, the growth of both bone and muscle being affected. In the choreic variety, where the arm is in constant motion, the muscles may become hypertrophied, but the bone remains short.

Prognosis.—As a rule, the prospect of recovery is bad. Even if the patient gets well, the hemiplegic side remains awkward.

Treatment.—Cod-liver oil and massage, which always relaxes the contracted muscles. The affected limbs should be used as much as possible.

DR. HARRIS inquired whether Dr. Sinkler had ever observed any hereditary disposition to convulsions and cerebral paralysis.

DR. SINKLER replied that the hereditary influence was decided even when no convulsions occurred.

DR. R. P. HARRIS read a report of the autopsy upon Mrs. Reybold, from whom two living children had been removed by

CÆSAREAN SECTION

by Professor Gibson, of the University of Pennsylvania. The superior strait was reniform; conjugate diameter, one and three-quarter inches; transverse diameter, five and a quarter inches. The malformation was due to rachitis and injury from a fall in her second year. A full report of the history of the patient, the operations, and the autopsy, is to be found in the *The American Journal of the Medical Sciences*, October, 1885, p. 422.

DR. E. E. MONTGOMERY reported the following case of

OÖPHORECTOMY:

Mrs. L., of Columbia, Pa., æt. 36 years; married ten years; pregnant five times, the last four years ago; was brought to my notice by Dr. A. F. Chase. Her health has been bad since her last confinement. First menstruation at twelve and a half years, regular and very free for one and a half years, when she fell, producing pelvic distress; after which, for seven years, the flow was very scanty, lasting but one or two days, and accompanied by excruciating pain. She improved somewhat after marriage. Her first conception was followed by so much nausea, vomiting, and anæmia that her physician advised and induced an abortion. She is now regular as to time, but irregular as to quantity; it is preceded by an excruciating pain for two days, which continues until the flow disappears; she also has severe pain in the head. She is very nervous at all times, but this is much intensified during the period. Pain is more marked in the left inguinal region and down the corresponding limb. Coition and vaginal examination are very painful. The uterus is enlarged and painful, tender on pressure over both ovaries. Local uterine treatment had been kept up during the entire four years, with no relief. Trachelorrhaphy had been performed. Ovariotomy was advised. September 19, 1885, she entered my private hospital, and, assisted by Drs. W. H. and C. B. Warder and E. Eshleman, the uterine appendages were removed. The left ovary was composed of a number of cysts, the largest of which ruptured while adhesions were being separated. The right ovary was not enlarged, but it was removed to insure relief. The wound was closed with silk-gut, and dressed with sublimated gauze and absorbent cotton. There was no shock. The highest temperature reached was 101.6°, at midnight of the 20th, and it became normal on the 22d. Sutures were removed on the eighth day, and the wound redressed for the first time. It had united throughout, and there was no irritation from the sutures. The effect upon her general health remains to be determined.

DR. MONTGOMERY also reported the following case of

SUPRAVAGINAL REMOVAL OF THE UTERUS AND BOTH OVARIES FOR FIBROID TUMOR.

Ann U., æt. 27, was brought to me by Dr. F. H. Boysen, of Egg Harbor City, with the following history: Her menses from the beginning occurred every three weeks and were free an entire week. During the last four years they have occurred every two weeks and are attended with pain in the pelvis and down the limbs, and severe pressure on the bladder, causing frequent urination and several times necessitating the use of the catheter. Dr. B. had diagnosticated fibroid tumor, which my subsequent examination confirmed. The tumor was the size of a child's head, filling up the pelvis and apparently arising from the anterior wall. The examination led me to believe that the bladder was adherent over the anterior surface and would render the removal of the tumor unsafe. I suggested the removal of the ovaries. She entered my private hospital September 15, 1885, for that purpose. Drs. W. H. Warder, Boysen, and Martin assisted; Drs. C. B. Warder and Stultweather were present. An incision three inches long was made, and finding the tumor free from the bladder, with cervix sufficiently long to serve for a pedicle, the incision was extended to within an inch of the umbilicus above and symphysis below, and the tumor with some difficulty withdrawn. In the absence of a Tait's clamp, which had been ordered some days before, the pedicle was constricted by a wire-écraseur and the tumor with the ovaries removed. The pedicle was then transfixed with two steel pins and tied in three sections with strong silk thread. The peritoneum was

Digitized by Google

fastened to the pedicle below the ligatures, and the wound closed with silk-gut sutures, the pins holding the stump outside. The wound was dressed with sublimated gauze and absorbent cotton. The operation was followed by some shock (temperature 97.4°, pulse 104), from which she soon rallied. She complained greatly of pain. A half grain of morphia had been given by suppository, and three hypodermic injections of morphia, one-quarter grain each, were given during the afternoon, before the pain was relieved.

At 3 A. M. of the 24th I was called by the nurse, who reported bleeding from the stump. Three ounces of blood had been lost. By aid of Dr. Warder, a Wells's clamp was applied below the pins, apparently controlling the hemorrhage; but it recurred later in the day from the angles and from beneath the clamp. By this time the Tait's clamp had arrived, and the patient was etherized, the lower three sutures removed, the pedicle drawn up, the clamp applied so as to control it completely, and the wound again closed. The wound had united throughout. Temperature had reached 100.6° at 9.30 P. M. The highest, subsequently, 101.6°, was in the afternoon of the 25th, and it became normal on the 28th. Upon removing the dressings, on the 27th, some pus welled up about the pedicle. As the skin was irritated, the dead pedicle was cut away, until the clamp slipped off. There resulted, of course, considerable retraction of the stump, but the sloughed tissue is now nearly cleared away. The patient suffers no pain or discomfort; temperature normal. The tumor was situated in the anterior wall and fundus of the uterus, and projected into the uterine cavity.

DR. PARISH remarked that removal of the ovaries had given such good results in cases of uterine fibroids, and was comparatively so free from danger, that he would like to hear from Dr. Montgomery his reason for his choice of operation.

DR. MONTGOMERY replied that the tumor filled the pelvis and pressed upon the bladder and rectum, causing great and constant distress. As diminution of the size of the fibroid tumor is not a certain result of oöphorectomy, and as all the circumstances were in favor of the major operation, he decided upon it as the best one.

MONTREAL MEDICO-CHIRURGICAL SOCIETY.

Stated Meeting, October 23, 1885.

THE PRESIDENT, THOMAS G. RODDICK, M.D., IN THE CHAIR.

DR. WM. GARDNER exhibited the following pathological specimens:

(1) A UTERUS SEPTUS WITH ATRESIA AND HÆMATOMETRA OF THE LEFT CHAMBER.

This specimen was exhibited at the meeting of the Canada Medical Association, at Chatham, Ont., and the description of it has already appeared in THE MEDICAL NEWS.

(2) A DERMOID OVARIAN CYST,

removed 15 days previously from a woman 47 years of age, some years past the menopause, and the mother of several children. The tumor was about the size of a large adult head and contained a grayish-yellow ochre-colored fluid, a bunch of hair, one tooth, and a plate of bone in the cyst wall. It had been of slow growth, causing very little in the way of symptoms, and was removed because such patients are in constant danger of peritonitis, bursting or suppuration of the cyst, and of axial rotation with consequent gangrene and hemorrhage within the cyst. Axial rotation of the tumor, Dr. Gardner remarked, is an accident to which dermoid cysts are especially prone. The patient made a good recovery.

(3) A SMALL SOLID OVARIAN TUMOR OF THE LEFT SIDE,

removed a week previously from a married woman, æt. 56, the mother of several children and five years past the menopause. The tumor measured 3 by 2½ inches, and was very hard and heavy. It contained a cyst as large as a small hen's egg, which was accidentally ruptured during the operation. The cut surface of the tumor was very firm, not markedly fibrous, and of a pale yellow color. The disease was limited to the ovary. The pedicle was slender, easily ligatured.

There was general enlargement of the fundus of the uterus, which also presented a nodulated projection. De. Wyatt Johnston had examined the tumor microscopically and found in the growth two different structures: the outer portion, which formed the bulk of the tumor, consisted of epithelial cells arranged regularly in circles and embedded in a matrix of fibrous tissue. The cells are uniform in size and do not infiltrate surrounding parts.

The central portion of the tumor had the same non-infiltrating epithelial cells, but the matrix consisted entirely of embryonic connective tissue, with abundant young spindle cells and nuclei. Dr. Johnston regards the tumor as non-malignant, for from its general appearance it looked as if the younger portion might be maturing into the old rather than that the more mature was having sarcomatous tissue added to it.

Dr. Gardner went on to say, that solid ovarian tumors are exceptionally interesting because of their rarity and frequent malignant nature; whatever this nature, if there be no evidence of infiltration of surrounding tissue, they ought to be removed. The propriety of this can only be determined by abdominal section. There is ample evidence, from the experience of Sir Spencer Wells and others, that unmistakably sarcomatous tumors of the ovary may be removed without recurrence for many years or indefinitely.

EXTIRPATION OF THE KIDNEY.

DR. HINGSTON exhibited a kidney which he had removed last August from a young girl aged 18. She had for some time complained of severe pain in the region of the left kidney and came to Dr. Hingston for relief. On examination the kidney was found enlarged and freely movable. Removal was decided on and the operation was performed. The lumbar incision was employed. No difficulty was experienced in the operation, there was no hemorrhage and the organ was easily enucleated. The girl made a rapid recovery. On examining the removed kidney it was found to be sacculated and filled with creamy fluid. The pelvis was filled with fibrous tissue and the ureter was occluded, being merely a fibrous cord. No vessels could be seen entering the hilus. It was probably a case of disorgani-

Digitized by Google

zation of the kidney due to congenital occlusion of the ureter.

EXTIRPATION OF KIDNEY FOR CALCULOUS PYELITIS.

DR. FRANCIS J. SHEPHERD showed a kidney which he had removed from a woman some five weeks before. The history of the case is as follows:

Eliza T., æt. 24, married, was admitted into the general hospital under Dr. Wilkins, on the 10th of August, 1885, suffering from emaciation, general weakness, and a painful swelling on the left side of the abdomen. Family history threw no light on the case, no consumption. Had herself always been healthy up to nine months before entrance into the hospital; at that time she began to lose flesh and to have pains in left side of abdomen which occasionally extended down to the thigh, but these were never severe. Has had four children and after birth of last child, five months ago, first noticed a tender swelling or rather fulness on left side of abdomen; at this time she noticed her urine was milky and that a deposit was thrown down when it was left standing for a short time. Had never passed any blood or had attacks of renal colic, nor had she ever had chills or sweatings.

When admitted into the hospital she was in a condition of extreme emaciation and very weak, pulse was 140 and temp. 100° F. She had no cough and her lungs were probably healthy. She had, however, frequent and painful micturition and the urine contained large quantities of pus; some days, however, it would be quite clear. On examining the abdomen the superficial abdominal veins were found much enlarged and a distinct fulness was seen in the left lumbar and iliac regions. Palpation revealed a large tumor which extended across the abdomen to within one inch of the umbilicus, above it reached as high as the spleen, and below could be felt reaching down as far as the brim of the true pelvis. By bimanual palpation the tumor could be grasped between the hands and moved slightly, no fluctuation could be distinctly made out. The tumor was very tender on pressure.

Towards the latter end of August, Dr. Wilkins transferred the case to the surgical wards under Dr. Shepherd. At that time her condition was better than on entrance and she had gained flesh. The tumor had not increased in size since she had been under observation, but her pulse continued rapid and her temperature ranged from 99° to 101.5° and other symptoms were much the same.

After a consultation with his colleagues Dr. Shepherd decided to explore the kidney, and to perform either nephrotomy or nephrectomy, as would be determined by the condition of affairs.

On September 17th, the patient having been etherized, the right kidney was first examined by palpation and made out easily to be normal in size and apparently healthy; it was freely movable. An incision was then made, as for colotomy, in left lumbar region, between the last rib and crest of the ilium, commencing at the outer edge of the erector spinæ muscle, and extending outwards for some five inches, the kidney tumor was soon reached and found to be freely fluctuating; it was aspirated and some stinking pus withdrawn; a needle was passed in and soon came in contact with a calculus. The tumor, which was somewhat larger than a child's head, was now freely incised and a large quantity of foul-smelling pus evacuated through the opening thus made. The finger was introduced and the pelvis was found filled with a large calculus; owing to the disorganized state of the kidney and the bad general condition of the patient it was decided immediately to extirpate the kidney—the upper end was first freed without difficulty, and then the lower end and posterior portion. These latter portions were freed with some difficulty, especially the lower end, which reached far down towards the true pelvis. To enable the hand to get in freely, the original incision was enlarged by incisions above and below at right angles, and several more incisions made into some of the pus-filled saccules. Now, the kidney was easily delivered through the wound and the vessels entering the hilus tied with silk and divided. The ureter, into which a portion of the calculus extended, was then ligatured and divided, and after cutting some strands of cellular tissue with scissors the kidney came away. Whilst freeing the kidney there was considerable venous hemorrhage from the torn vessels at upper and posterior part, which, owing to the presence of the tumor, was much engorged. This was stopped by sponge pressure.

The large cavity caused by the removal of the kidney was quickly filled up by the intestines pushing forward the peritoneum. The cavity was washed out with bichloride 1 to 2000, and a large drainage tube introduced. The wound was brought together with catgut sutures and dressed with iodoform powder and sublimate jute pads.

The patient, although suffering considerably from shock, recovered well from the operation. She had some vomiting, which was controlled by champagne, and for the first twenty-four hours had brandy and beef-tea per rectum.

During the first night there was considerable oozing, and the dressings had to be changed the second day. At this dressing the drainage tube was much shortened. More than thirty ounces of urine were passed the day after operation. Her pulse, which after the operation was very weak and 160, soon fell to 120, and temperature after first day never reached 100° F. The woman rapidly recovered, and the wound with these dressings healed by first intention, except at the point where drainage tube had been. At the end of the third week she was able to wheel herself about the ward in a chair, and during the past week has been walking about. Her appetite is good and she is rapidly regaining flesh. The daily amount of urine excreted is from thirty-five to forty ounces.

The kidney was now exhibited and was seen to be of large size and composed of a number of saccules which had contained pus; the pyramidal portion had all disappeared, and the cortex was about quarter of an inch thick. The pelvis was filled with a large oxalate of lime calculus which extended down into the ureter, almost completely blocking it up. In one of the saccules at the lower end of the kidney was a small round calculus the size of a marble. Dr. Shepherd said about a pint of pus had been removed from the kidney.

DR. FENWICK congratulated Dr. Shepherd on the success of his case, and said that it had never been his fortune to remove a kidney, although he had many times seen it whilst performing colotomy, and had occa-

Digitized by Google

sionally cut down on it for abscesses in its neighborhood. He had always thought that there was not much difficulty in the operation, and that if the patient survived the shock the prognosis as to recovery was good.

DR. HINGSTON asked why Dr. Shepherd did not remove the stone and leave the kidney, and why he cut the quadratus lumborum muscle.

THE CHAIRMAN said he had been present at the operation, and thought that Dr. Shepherd had acted properly in removing the kidney, as the woman's condition was such that she could not have stood the drain which must have still gone on had the stone merely been removed; besides, removal of the stone could not have been effected without further serious injury to the organ. He was pleased to find how much more room was obtained by making incisions at right angles to the first one, and how easily the kidney was delivered when this was done. He himself had never performed nephrectomy, though some two years ago he had performed nephrotomy in a case of scrofulous pyelitis; the patient was relieved by the operation, but subsequently died of phthisis.

DR. SHEPHERD, in reply, said that he did not think removal of the stone could have been easily accomplished without so much injuring the kidney as to render it useless; as it was, the kidney was so disorganized that he did not think it worth preserving, and the woman's condition before operation was so bad that he thought complete removal of the source of disease was by far the best procedure. He had cut the quadratus lumborum muscle so as to get more room posteriorly. He always did so when performing colotomy, and it never interfered with good result of the operation. Dr. Shepherd considered the operation more dangerous than difficult.

DR. TRENHOLME reported that the two cases of

EXCISION OF THE UTERUS

he had brought before the Society some weeks ago were doing well (one excision having been for uterine fibroid, and the other for cancerous disease).

CORRESPONDENCE.

BANDAGE FOR THE FIXATION OF THE HUMERUS AND SHOULDER GIRDLE.

To the Editor of THE MEDICAL NEWS.

SIR: Dr. Cabot's note in your issue of October 31st, on the bandage for fixation of the humerus and shoulder girdle, described by Dr. Dallas, leads me to say that in my experience the object of the bandage, so far as it relates to making "pressure upon the top of the shoulder and at the same time driving the humerus strongly up toward the socket," can be very effectually and, I think, more conveniently attained by a strip of adhesive plaster passing from a point between the shoulder blades, over the top of the shoulder, down the front of the arm, under the elbow, up the back of the arm, and over the shoulder again, to the chest in front. I have used this dressing in dislocations of the acromial end of the clavicle, fracture of the clavicle close to that joint, and in fracture of the humerus high up without displacement, and have been entirely satisfied with its action. A case of the first-named injury successfully treated in this manner was presented to the New York Surgical Society about two years ago.

Very truly yours,

LEWIS A. STIMSON,

NEW YORK, 34 EAST THIRTY-THIRD ST.,
November 2, 1885.

THE CARE OF THE PERINEUM DURING LABOR.

To the Editor of THE MEDICAL NEWS.

SIR: In your report of the proceedings of the late meeting of the American Gynecological Society (issue of October 3) Dr. T. A. Reamy, of Cincinnati, contributed a paper upon the care of the perineum during labor, in which he proposes to protect it by a "towel or bandage ten inches wide and forty or fifty inches long, carried around the buttock of the patient and over the hemisphere produced by the bulging perineum, with the upper edge on a level with the fourchette, and the ends given to assistants, who are instructed to make traction during the pain, in the manner the accoucheur may direct."

This procedure is referred to as being wholly new, and certainly it has not been described in any text-book or journal that I have been able to consult, but in the address in Obstetrics at the meeting of the Medical Society of the State of Pennsylvania, May, 1884, I referred to a method of protecting the perineum during labor, based upon precisely the same principles, though differing slightly in detail.

I quote from the address as published in the *Transactions:*

"To carry out the points made by Playfair and Goodell, viz., to relax the tissues of the perineum, I have recently used a towel about four feet long, folded lengthwise to a width of six or eight inches, passed in front of the pubes and over the trochanter, the free ends secured by two strong safety pins, over a firm pad resting against the os coccygis and anal orifice. The effect of this is to crowd the surrounding tissues in the direction of the vulvar outlet, securing all the relaxation that is possible, at the same time keeping the head pressed towards the pubic arch. The action of this pad and band is pleasant to the patient and effectually protects the coccyx from injury, which, as is well known, is often the cause of that most serious malady, coccygodynia. At the moment of greatest distention, the action of the band should be aided with the left hand of the accoucheur, while the other resists the too rapid advance of the head, by direct and firm pressure."

I am not surprised that my views had not met the eye of Dr. Reamy and others who participated in the discussion, for papers once in the *Transactions* are securely entombed. Yet, as a matter of history, I think it right to call the attention of your readers to the views advanced in that address.

Respectfully,

JACOB PRICE.

WESTCHESTER, PA., October 21, 1885.

TYPHO-MALARIAL FEVER.

To the Editor of THE MEDICAL NEWS.

SIR: In THE MEDICAL NEWS of September 13, 1884, Dr. R. Bartholow had an article upon typho-malarial fever. It was my intention at that time to reply to Dr. Bartholow and treat the subject fully, but various causes combined to prevent the consummation of my desire, and only a preliminary note is here presented. As bearing upon the question so positively settled in the closing sentence of that communication, I wish to present for consideration some facts concerning the malarial fevers of the far West, intermittent and continued, as they exist along the slopes of the backbone of the continent—*i. e.*, the Rocky Mountain Range, its spurs and table lands.

Dr. Bartholow lays down the following propositions, which I alter somewhat from their arrangement in his article: "Typhoid is the fever of old, of cultivated countries and dense populations; malarial, of new countries and sparse populations.

"Typical typhoid is capable of many modifications and clinical variations, under climatic and other conditions, but its morbid anatomy *never* varies. There is no special type of fever entitled to the name typho-malarial."

In reply to these assertions, I will state that the continued form of the so-called "mountain fever" is a continued remittent fever, resembling typical typhoid in its clinical history; but wanting the typical and clinical course of pure typhoid; each period not corresponding to a certain degree of fever, therefore the diagnosis cannot always be made from the fever course. Its duration is from two to five weeks, occasionally longer. It is a fever of *new* and *sparsely populated* countries; its habitat, aptly expressed by its popular name, is in the mountains and mountain valleys, at varying altitudes, where the soil is dry and rocky, with no subsoil water, and where it is utterly impossible that there should have been any contamination of the surface ground by typhoid germs, within the memory of the races now peopling this continent. It prevails simultaneously with the intermittents, and apparently is contracted under the same conditions. It attacks, chiefly, those persons outside of large settlements, such as wood-choppers, prospectors, teamsters, ranchmen, etc. It is also occasionally found in the towns, but those whom it there attacks have usually passed through a period of extra-mural exposure.

The morbid anatomy of "mountain" fever *never varies*, and microscopically is that of pure typhoid, *i. e.*, infiltrated mesenteric glands, enlarged spleen, with ulceration of Peyer's patches. This disease first came under my professional observation in 1877, and in that year I made my first autopsy of a case of mountain fever. Since that time exceptional opportunities have been accorded me for observing and treating the disease, and I have made thirty post-mortem examinations of the viscera of patients dead of this malady.

If Dr. Bartholow is correct in his statement that typhoid fever "is the fever of old, of cultivated countries and dense populations; unchangeable in its morbid anatomy, and that this morbid anatomy is an infallible proof of this disease;" then, as a resultant of my own experience, having, in the last five years alone, treated nearly four hundred cases of mountain fever both in hospital and private practice, invariably finding the same post-mortem lesions as exist in the "pure typhoid of old settlements," I am forced to the conclusion that either typhoid fever is *not* essentially the disease of old communities and dense populations, and does not always originate there; or, that there is a disease, in many of its clinical manifestations, closely resembling typhoid, presenting identically the same pathological appearances, which has its origin and home far from towns and settlements. The doctrine of descent and development is as applicable to the microörganisms causing disease, or to disease considered as an entity, as to any part of the animal or vegetable kingdoms.

May not this frontier fever, this continued malarial "mountain" fever, be the uncivilized progenitor of the typhoid of civilization?

In the course of the ensuing year I hope to be able to publish a more extended account of this disease with clinical history of cases, etc.

Respectfully yours,

G. E. GOODFELLOW, M.D.

TOMBSTONE, A. T., October 9, 1885.

NEW INVENTIONS.

A NEW BINAURAL STETHOSCOPE.

BY WILLIAM A. EDWARDS, M.D.,

FIRST ASSISTANT DEMONSTRATOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA, MEDICAL REGISTRAR PHILADELPHIA HOSPITAL.

THAT binaural stethoscopes have not received from American physicians the attention that they demand is in part due, I think, to the lack of efficient and handy instruments. The majority of practitioners will not use an instrument that is bulky, inconvenient for ready carriage from patient to patient, or is awkward in its application.

Professor William Osler has had constructed a binaural stethoscope by Hawksley, of London, of which the accompanying cut is almost an exact counterpart, excepting two essential changes in the mechanics of the instrument, which have been added by Mr. Yarnall, the instrument maker.

The instrument (Fig. 1) is constructed in two separate parts; two fixed converging nickel tubes, and two flexible rubber tubes. The bone buttons on the nickel tubes are to be placed in the external auditory meatus; the buttons

FIG. 1.

are removable, and are constructed of various sizes, in order to fit each individual ear, which, I consider, is an essential point for the successful use of the instrument.

At the lower converging ends of the fixed nickel tubes is placed a rubber band, in order to hold the instrument firmly in the ear when in use.

Two cloth-covered rubber tubes, converging to a com-

Digitized by Google

mon bell-shaped, hard-rubber cap, which is to be placed on the patient's chest, complete the instrument; and, as such, Professor Osler and myself are in the habit of recommending it to the consideration of the students in the University.

I would formulate the points in favor of the instrument about as follows:

1. Its lack of "bulkiness," so common in all other binaural stethoscopes.

2. Its property of disarticulation, rendering the instrument just about the size of a single or monaural stethoscope (Fig. 2).

FIG. 2.

3. The facility with which it can be applied to the chest, not necessitating the practitioner's assuming constrained or uncomfortable attitudes.

4. The fact that this instrument allows the physical diagnostician to observe the locality that he is studying during the operation, and also enables him to avoid undue pressure.

5. The clearness with which it conducts sounds to the ear, and its great utility in the study of indistinct valvular disorders and hæmic murmurs.

The instrument is made in Philadelphia, at 115 South Tenth Street, by Mr. E. A. Yarnall, who calls it the "University Stethoscope."

300 SOUTH THIRTEENTH ST., PHILADELPHIA.

AN IMPROVED FORM OF REFRACTION OPHTHALMOSCOPE.

BY EDWARD JACKSON, M.D.,
CHIEF OF THE EYE CLINIC IN THE PHILADELPHIA POLYCLINIC.

THIS is an improvement, over earlier forms of refraction ophthalmoscope, in the arrangement of the lenses. The generally used Rekoss disk is discarded; and the lenses arranged in two narrow straight slides, which move immediately behind a rectangular tilting mirror of the usual focal length. The slides extend downward within the stem of the instrument; and at the lower extremity are furnished with milled projections, by which they are moved. The accompanying representation of the instrument renders a more minute description superfluous.

The lenses are selected and placed, five in each slide, so as to give single glasses or combinations of the following refractive powers:

Convex 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5, 6, 7, 8, 9, 10, and 11 dioptrics.

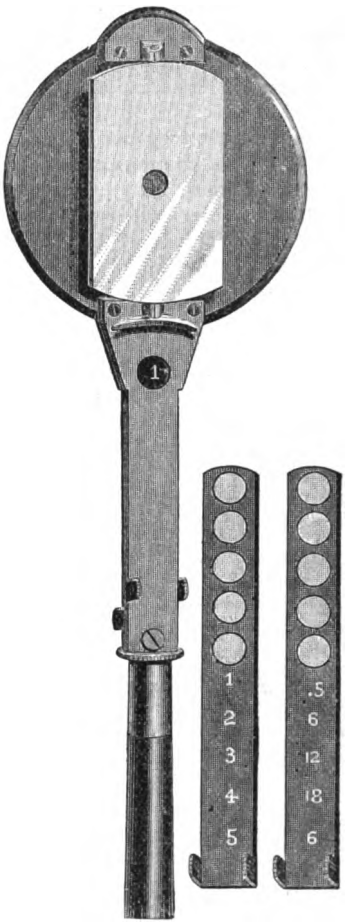
Concave 0.5, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, and 18 dioptrics.

The instrument is believed to possess these advantages:

1. It is the lightest, thinnest, simplest refraction ophthalmoscope yet devised.

2. The whole of this most valuable refractive series is obtained by a slight movement of the forefinger, without ever taking the instrument from the eye.

3. The hand holding the instrument can be further from the patient's face than is possible when the Rekoss disk is employed, unless recourse is had to some more complicated mechanism such as the toothed wheel of Fox's and Juler's ophthalmoscopes.



To the makers, Messrs. Queen & Co., of Philadelphia, I am indebted for important suggestions, and the mechanical working out of the instrument.

A LARYNGEAL APPLICATOR.

BY ALEXANDER W. MAC COY, M.D.,
OF PHILADELPHIA.

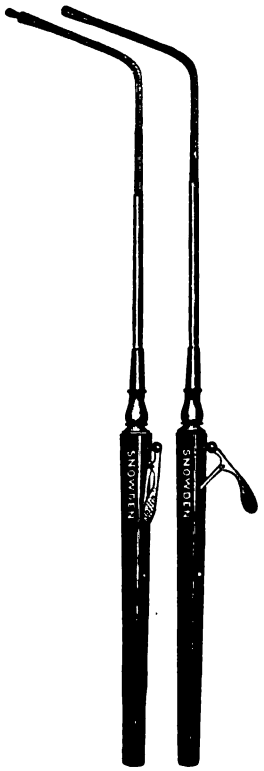
THE accompanying figure represents a laryngeal applicator, for applying certain caustics, after fusing them on the roughened aluminium point.

The features of superiority claimed for the instrument are the following:

1. A double-acting lever movement.

2. Uncovering of the stylet by drawing the tube backwards instead of *pushing out* the concealed stylet (the usual method), and thereby avoiding the aberration at the point.

Digitized by Google



3. Flexibility of the stylet and tube, allowing a variety of positions, and diversity of uses.

4. Self-recovery of the tube by a spring in the handle.

NEWS ITEMS.

THE NEW YORK POLYCLINIC. — The necessity for post-graduate instruction seems increasingly felt, as this institution opens this year with a larger class of practitioners on its roll of students than ever before, and since its opening three years ago, over 600 physicians have registered in the various classes.

PUBLIC OPINION ON THE CONGRESS ORGANIZATION.—Discussion, so far, has done little to stay the ruinous course pursued by the malcontents of the New Orleans meeting in regard to the International Congress. The new combinations of the Chicago and New York Committee meetings have only made a bad matter worse.

When we look back upon the whole affair from this standpoint, we cannot help feeling that those gentlemen who represented the International Medical Congress made a very unwise move in asking the American Medical Association to take any part in the construction of the forthcoming meeting. These gentlemen would have done far better by taking the whole responsibility upon themselves, and this course would have been satisfactory to the members of the last Congress, the evidence of which we have in Sir James Paget's letter to Dr. Hays.

The discourtesy of the American Medical Association towards the original committee seems not to occur to the reconstruction committee, and there can be but one interpretation of the whole matter—the new committee intends to organize a Congress upon a basis so objectionable that it has already divided the profession into two parties. If the gentlemen composing this new organization are willing to undertake it, they cannot be prevented, but it would be well if they could be, both for the success of the Congress and the unity of the profession.—*North Carolina Medical Journal.*

The belligerent members of the American Medical Association claimed and exercised the right to revise, amend, and alter the work of the original committee on the International Congress, and they did alter it with a vengeance by virtually kicking the old committee out of office and starting over again. Now the new committee do not propose to have any one criticise, revise, amend, or alter their work, and consequently have resolved "That the actions of this Executive Committee are final, not being subject to revision, amendment, or alteration, either by the Committee of Arrangements or the American Medical Association." We do not believe this resolution, however, unanimously adopted by the committee, will save them from a general overhauling at the St. Louis meeting in May, 1886.—*Peoria Medical Monthly.*

The unhappy Committee on Organization, like Sisyphus, is still at its work, which falls down as fast as it builds it up. No committee has ever labored under such difficulties. It was unfortunate in its origin, and has been unlucky ever since. It inaugurated at Chicago a narrow and illiberal policy, which very soon resulted in disaster. Resignations began to decimate the rank and file of the various sub-committees and sections, and has continued ever since. Many new appointments have been made, but the process of disintegration exceeds the work of repair. The result, at this rate, is inevitable.—*The New Orleans Medical and Surgical Journal.*

PRECAUTIONS AGAINST SMALLPOX.—The Wisconsin State Board of Health has just issued a circular from which the following extract is made:

It is matter of common knowledge that smallpox in virulent form has for some time past been prevailing in Canada, from which it has been hoped to protect the United States by the rigid inspection of all persons passing from that country into this. Notwithstanding this precaution, smallpox has very recently appeared in this State in a family direct from Montreal, and before the existence of the disease was known, many persons had been exposed to the contagion. It is hoped that in this case, as in a previous recent outbreak of this disease (also brought from Montreal), vigorous measures may prevent an epidemic, but these occurrences, and the fact that smallpox has lately appeared in several other States, should be accepted by all health authorities, and by the public, as a sufficient warning that this is a time of special danger, and that smallpox may at any time be brought to any community.

The State Board of Health earnestly advises all persons who have not been successfully vaccinated within five years, promptly to secure, both for their own sakes and as a duty they owe to the public, the protection from smallpox which a recent successful vaccination confers.

Throughout the State, local boards of health are advised to watch carefully for a period of two or three

Digitized by Google

weeks from the date of their arrival, all newcomers within the territory under their supervision, and, especially, those coming from an infected district, making sure if any sickness occurs in such persons or families, that its character be known. It is especially advised that in all places where lumbering operations are carried on, or in which large bodies of men are employed in any capacity, every effort should be made to secure their general vaccination, and it would, in many places, be both wise and economical to have this done at public expense.

THE FAC SIMILE OF HARVEY'S MS. LECTURES.—As our readers have been informed, Harvey's MS. Lectures will soon be published in fac simile of the author's handwriting, accompanied by an interleaved transcript in ordinary printer's type. We learn from the *Medical Times and Gazette*, that the work is making good progress, and that Messrs. Churchill have every expectation of issuing it to the subscribers early next year. The photographic reproduction has been very successful, so that many of the MS. passages come out more legibly than in the faded and time-worn original, a result which has not a little facilitated the labors of the transcriber.

THE ROMAN SANITARY CONFERENCE.—The question of the reassembling of the International Sanitary Conference at Rome is, according to *The Lancet*, still unsettled. It will be remembered that as soon as the Technical Commission had presented the result of its labors to the full Conference, that body was adjourned until November 16th. According to the *Popolo Romano*, some of the States which were represented at the Conference in May last have not yet sent in their adhesion to the proposal for its reconvocation.

DECLINE OF THE CHOLERA IN FRANCE.—U. S. Consul, Frank H. Mason, at Marseilles, France, writes to the Department of State under date of October 1, 1885, as follows:

Since the last sanitary report from this Consulate, September 9th, the cholera, which had at that time spread throughout a large part of this district, has gradually subsided, and the epidemic may now be said to have reached its final stage. There are now recorded from three to five choleraic deaths per day in Marseilles, but they are nearly all among the fugitives who have returned to their homes without due precautions in respect to ventilation and disinfection, and have been imprudent in their diet or habits.

The record of deaths from Asiatic cholera in this city from the commencement of the epidemic to the last day of September inclusive, is as follows:

Month of July	44
Month of August	956
Month of September	230
Total	1230

These are the figures officially given by the sanitary authorities. It is certain, however, that for the period from the 30th of July until the 21st of August, at which date the city journals began publishing the death list, they are understated, and that the real number of deaths from cholera during August was 1174 instead of 956. The difference between these two totals records the choleraic deaths registered simply as "children," and the numerous persons who died from complications of cholera and other diseases, under such conditions that the attending physician felt justified in reporting the death as one which would not preclude an ordinary funeral.

The total deaths from all causes for August and September numbered as follows:

For August.

From cholera	956
" typhoid fever	100
" typhus fever	4
" measles	10
" whooping-cough	11
" scarlatina	5
" smallpox	34
" diphtheria	22
" pulmonary consumption	131
" convulsions	87
" apoplexy	44
" diarrhœa	24
" gastroenteritis	88
" stillborn	75
" accidental	8
" meningitis	120
" cerebral congestion	42
" pneumonia	48
" enteritis	124
" uterine cancer	12
" suicides	10
" all other causes	346
Total	2301

The large mortality ascribed in these tables to "convulsions," "cerebral congestion," and "apoplexy" may be, in a great measure, ascribed to cholera, those sudden and violent maladies being used as euphemisms for the Asiatic malady under the circumstances above described.

The details of the mortality for September are not accessible. The record kept at this Consulate shows a total list of 1082 deaths, of which 230 were due to cholera. On the basis of these official statistics, the epidemic of 1885 has claimed, therefore, down to the present date, 1230 victims, or two-thirds of the whole number that perished from cholera during the scourge of 1884. This is an unusually fatal record for a second year's visitation at Marseilles, the mortality of these secondary outbreaks having been uniformly less than half that of the preceding summer.

At Toulon, the course and subsidence of the malady have been precisely similar to that in Marseilles, except that it began a month later, and was relatively more fatal during the worst period of the epidemic. The most fatal day at Toulon was the 27th of August, on which date there were recorded in that city 42 deaths from cholera.

At Marseilles, the scourge reached its highest mortality on the 21st of the same month, with a record of 69.

Digitized by Google

On the 11th of September the cholera death-rate at Toulon had declined to six per day, and since then it has fluctuated from one or two, and some days more, up to seven or eight daily. These sudden and temporary recrudescences have been ascribed wholly to the return of fugitive families to their homes, which had remained closed or badly ventilated during their absence, and they enforce anew the importance of those precautions which have been described in previous reports of this series as imperative under such circumstances. As a principle, a person having once left an infected city, should remain away until the last trace of the epidemic has disappeared, and then return only to lodgings thoroughly renovated and prepared.

At Cette, where the cholera was announced in these dispatches as having appeared on the 6th of September, the disease was promptly suppressed, but as it has continued to prevail to some extent at various points in the Department of Herault and Garde—in the former of which Cette is located—I have thought it prudent to require the Consular Agent at that port to employ a Medical Inspector, and continue the careful examination of all vessels clearing from that port for ports in the United States.

It is a pleasure to be able to close the record of this epidemic without including among its victims the name of any citizen of the United States. This is the more gratifying in that the malady was, particularly in its earlier stages, peculiarly fatal to foreigners, notably English and Scandinavians.

The few American families who reside here are mostly in circumstances which enable them to spend the hot months away from the city. Such as remained here have, as usual, taken all wise precautions, and have avoided the carelessness and excesses which are in so many cases fatal to other foreigners.

Two American vessels were in port during the early and most fatal stage of the epidemic. Upon depositing their papers at the office, their captains were informed of the actual sanitary condition of the port, and urged to see carefully to the food of their men, keep them on board at night, and prohibit drinking and all other excesses. They were also provided with the formula of a remedy to be used immediately in all cases of diarrhœa or choleraic attack.

Both vessels, after discharging cargoes here, went to Hières, a small port near Toulon, where they loaded with salt for Boston and New York. While here and at Hières, there were in all, on both vessels, nine cases, including both captains, of acute choleraic diarrhœa. One of these masters was seized during the night while his vessel was moored in the worst part of the old port, with profuse vomiting and dejections, cramps and chills, all the symptoms of Asiatic cholera which then prevailed among the shipping and on shore in his immediate neighborhood. He used the remedy, called no physician, and two days afterwards his vessel cleared for Hières. All the nine cases on board both ships were similarly treated, and all survived, though it was afterwards found necessary to return one of the sailors to a hospital in Marseilles, where he ultimately recovered.

The usual result of experience is to inculcate extreme diffidence with reference to the many alleged specifics for cholera. There are circumstances under which all remedies seem alike powerless and ineffective. But if the experience of the past summer can add any therapeutic suggestion to what has been said in previous reports of this series, it would be to recommend the remedy which was used in the cases of the American captains and their crews. It is the prescription of the lamented Dr. Valentine Mott, of New York, one of the foremost physicians of our country. It embodies the results of his experience in three successive epidemics of cholera, and was used by his own son during the pestilence of 1884 at Toulon and Signes, with extraordinary results. Its formula is:

Tincture of rhubarb	10 parts.
Extract capsicum	2 "
Laudanum, Sydenham . . .	4 "
Camphor	℥ "
Syrup of ether	50 "
Syrup bitter orange peel . . .	50 "

Sig. One teaspoonful in a little water, and repeat until symptoms cease.

It cannot be said that the epidemic of this year has been fertile in scientific results. Little, comparatively, has been done either here or at Toulon in the direction of experimental or scientific inquiry. The verdict of last year's investigation was, "We have shown what cholera is *not*, but we cannot tell what it is." With that result and the generally accepted overthrow of Dr. Koch's theory, the medical men of this region, while awaiting the probably similar collapse of the Ferrán inoculation process in Spain, have been content to treat the epidemic of this year not as an opportunity, but as an affliction, to be fought down as quickly and quietly as possible.

It is doubtful whether the final statistics will show that any substantial progress has been made in treating the most malignant forms of the disease, or that the proportion of deaths to cases has been reduced so much as one per cent. by all the experience of those two sombre years. The one effective treatment for Asiatic cholera is to avoid it. The remedies are intelligence, temperance, correct living—that individual religion of the body which is an essential part of human civilization—supplemented by the improved drainage, ventilation, and municipal cleanliness which are the basis of modern sanitary science. France, Italy, and Spain, the Latin nations of the Mediterranean, have suffered as examples to other and less exposed countries, of the negligence which becomes perilous in the presence of cholera; and it will be unpardonable if the lesson is not thoroughly learned and practically utilized.

PASTEUR'S DISCOVERIES IN INOCULATION FOR HYDROPHOBIA.—A recent cablegram to the *New York Herald* states that Dr. Louis Pasteur's experiments have resulted in a most brilliant success. At perhaps the most important sitting held by the Academy of Sciences, Dr. Pasteur thus described the process of cure by means of a rabbit inoculated with the fragment of a tissue taken from the spine of a rabid dog. The inoculation of the poison occupied fifteen days. As soon as the first rabbit inoculated was dead, a portion from its spinal marrow was, in turn, inoculated into a second rabbit, and so on until sixty rabbits had been inoculated. At each successive inoculation the virus increased in potency, and the last period of incubation did not occupy more than seven days.

Digitized by Google

Having ascertained that exposure to dried air diminished the virus, and consequently reduced its force, Dr. Pasteur supplied himself with a series of bottles of dried air. In these bottles he placed portions of inoculated spinal marrow at successive dates, the oldest being the least virulent and the latest the most so. For an operation, Dr. Pasteur begins by inoculating his subject with the oldest tissue, and finishes by the injection of a piece of tissue whose bottling dates back only two days, and whose period of incubation would not exceed one week. The subject is then found to be absolutely proof against the disease.

A boy, 12 years of age, named Meister, who had been bitten fourteen times, came from Alsace with his mother to see Dr. Pasteur. The autopsy of the dog which had bitten the boy left no doubt as to its having suffered from hydrophobia. Dr. Pasteur took the celebrated Dr. Vulpian and a Professor of the School of Medicine to see the boy Meister. These two doctors came to the conclusion that the boy was doomed to a painful death and might be experimented upon. In thirteen days inoculations were made upon Meister with pieces of spinal marrow containing virus of constantly increasing strength, the last being from the spine of a rabbit that died only the day before. Now a hundred days have passed since Meister underwent the last inoculation. The treatment has been thoroughly successful, and the boy is in perfect health. He had been bitten sixteen hours, and had travelled from Alsace to Paris before the first inoculation was performed.

A shepherd boy named Judith, aged 15, was bitten by a mad dog a fortnight ago and has now been a week under treatment. Dr. Pasteur is confident of curing him.

Dr. Pasteur said that it was now necessary to provide an establishment where rabbits might always be kept inoculated with the disease. In this way a constant supply of spinal tissues of old and recent inoculation would always be ready. Before the sitting was adjourned, Dr. Pasteur received an enthusiastic ovation, from both the Academy itself and the public who were present. Among those present I noticed the Grand Duke Alexis, who is a great dog fancier, and M. de Lesseps, who went to hear Dr. Pasteur's report endorsed by Dr. Vulpian.

One of the leading doctors present remarked that the question was whether a man, cured of hydrophobia, could suffer from a second bite—in other words, whether the inoculation of virus was a guarantee against hydrophobia. In answer, Dr. Pasteur states that the malady is transmissible only by bite. If, therefore, by a general compulsory inoculation for several generations, dogs had been made incapable of hydrophobia, the malady would have disappeared, and there would be no occasion to ask whether inoculation had a permanent effect or not. As to the origin of hydrophobia, Dr. Pasteur says nobody in the world can explain its primal causes. As he remarked—perhaps out of politeness—his theory will require study by the profession in order to make it practical, but he emphatically stated that the cure for hydrophobia had been found.

THE GRAEFE MEDAL AND PRIZE.—It was determined by the Heidelberg Ophthalmological Society, soon after the death of Albrecht Von Graefe, to found, in honor of his memory, a gold medal to be awarded every ten years, for the most distinguished work done in ophthalmology. The first medal has just been unanimously decreed by the Society to Professor Helmholtz, of the Berlin University.

After Graefe's death, a prize was also founded by the late Professor Welz, of Würzburg, to be awarded every third year for articles appearing in the *Archiv für Ophthalmologie*, founded by Graefe, which the Ophthalmological Society deemed most deserving of it. The fifth award has been made to Dr. Samuelson, of Cologne, the former prizes having been presented to Professor Leber, of Göttingen, to Dr. R. Weber, of Darmstadt, to Dr. Knies, of Zurich, and to Dr. von Güdden, of Munich.—*Medical Times and Gazette*, October 24, 1885.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM OCTOBER 27 TO NOVEMBER 2, 1885.

MCELDERRY, HENRY, *Major and Surgeon.*—Granted leave of absence for four months from November 1, 1885.—*S. O. 246, A. G. O.*, October 26, 1885.

PATZKI, J. H., *Captain and Assistant Surgeon.*—Appointed member of Board to meet at Forts Jackson and St. Philip, La., on November 5, 1875, to select a site for the new quarters for the advance sergeants at those posts.—*S. O. 230, Department of the East*, October 28, 1885.

TOMEY, G. H., *Captain and Assistant Surgeon.*—Granted leave of absence for two months, to take effect after the return from leave of absence of J. C. Baily, Major and Surgeon.—*S. O. 87, Division of the Atlantic*, October 24, 1885.

EWING, C. B., *First Lieutenant and Assistant Surgeon* (Fort Leavenworth, Kansas.)—To accompany Congressional Committee of which Hon. W. S. Holman is Chairman, in its visit and inspection through Indian Territory.—*S. O. 160, Department of Missouri*, October 21, 1885.

IVES, F. J., *First Lieutenant and Assistant Surgeon.*—Relieved from temporary duty at Fort Laramie, Wyoming Territory, and ordered to Fort D. A. Russel, Wyoming Territory.—*S. O. 106, Department of the Platte*, October 22, 1885.

MORRIS, E. R., *First Lieutenant and Assistant Surgeon* (recently appointed).—Assigned to duty at Fort Bayard, New Mexico. He will continue on detached service under orders of District Commander.—*S. O. 160, Department of Missouri*, October 23, 1885.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING OCTOBER 31, 1885.

AUSTIN, H. W., *Surgeon.*—To proceed to Portland, Maine, on special duty, October 31, 1885.

CARTER, H. R., *Passed Assistant Surgeon.*—When relieved, to proceed to New Orleans, Louisiana, and assume charge of the Service, October 27, 1885.

BATTLE, K. P., *Assistant Surgeon.*—Granted leave of absence for thirty days, October 27, 1885.

WILLIAMS, L. L., *Assistant Surgeon.*—To proceed to Chicago, Illinois, for temporary duty, October 28, 1885.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL ARTICLES.

THREE CASES OF ACUTE ENDOCARDITIS; EVIDENCES OF DYNAMIC MITRAL STENOSIS.

BY JOHN GUITÉRAS M.D.,

PASSED ASSISTANT SURGEON, U. S. MARINE-HOSPITAL SERVICE, FORMERLY PHYSICIAN TO THE PHILADELPHIA HOSPITAL.

CASE I.—Lizzie H., æt. 11 years, colored, was admitted to the Charleston City Hospital, on September 15, 1885, suffering with acute rheumatism. On admission it was said that the joint trouble had subsided considerably, but the patient complained of pain in the præcordia, between the shoulders and in the head, and also of some soreness of the extremities. On percussion there was dulness over the entire left thorax. Nothing could be made out by auscultation of the heart, except that its action was irregular.

The temperature ran as follows according to the Fahrenheit scale:

September	15TH.		16TH.		17TH.		18TH.	
	M.	E.	M.	E.	M.	E.	M.	E.
Temperature ...	103°		102.8°	103.6°	102.8°	104°	102.8°	died.

On post-mortem examination the left lung was found adherent to the chest walls, and was the seat of acute pneumonia.

The above notes have been kindly furnished by the Resident Physician, Dr. Eleazer. I saw the heart many hours after the autopsy, and found that the aortic valves were fringed with grayish, soft vegetations which projected into the aorta in the shape of a large cauliflower excrescence. The rest of the heart was, to the naked eye, healthy.

CASE II.—C. W., a seaman, 55 years old, was admitted to the Marine Ward, in the Charleston City Hospital, on September 16, 1885. The following is taken from the notes of my Resident Physician, Dr. Caldwell. The patient has had measles, scarlatina, variola, yellow fever, and malaria. He never had rheumatism, and there are doubts concerning syphilis. He was taken sick in Brunswick, Georgia, a malarious locality, about six weeks ago. His symptoms were fever, dyspnœa, and weakness. Of the former, he states that it came on at nights, and was followed by very profuse perspiration.

I may add that, on inquiry from the wife of the patient, I failed to elicit any history of chronic cardiac trouble. He had had, in fact, no sickness except malaria, for many years. It is interesting also to note that on the day of admission the patient walked considerably about the city, and came twice up two flights of stairs to my office, though, of course, with great difficulty.

Dr. Caldwell adds that on inspection he found a well-marked epigastric impulse, and a faint apex beat in the sixth interspace, one inch outside of the line of the nipple. The pulse was 128. There was moderate general anasarca, more marked in the lower extremities. These had swelled more during the day, causing him some pain. There was a continued murmur heard about the apex. The vesicular murmur was good throughout the chest. The patient was not emaciated, but very pale. His lips were bluish, and the hands quite cold. The urine contained no albumen.

Sept. 17.—I confirmed the above observations, and added the following: There is orthopnœa. The pulse is regular, frequent, of medium size, but gaseous. There is some pulsation at the base of the neck. The heart is beating rapidly, yet the following physical signs can be made out with sufficient accuracy: A continued soft roaring murmur (such as is produced in a shell), with a presystolic accentuation, is heard over the body of the heart. The diastolic portion of this murmur, which is the longest and most prominent portion, loses rapidly in intensity above the third interspace, and is lost at the second right costal cartilage. Downwards the murmur holds its own to the apex, and one inch to the left of it, and disappears rapidly beyond this point. It is heard with equal intensity along the left border of the left ventricle, at the apex, and up along the lower portion of the right border of the heart. The murmur is undulatory, and leads up to a distinct (more distinct, in fact, than anything else about the cardiac cycle) presystolic accentuation, which terminates with a feeble first sound. The latter is accompanied by a murmur similar in character to the diastolic, except that its pitch is a little higher, and that it is heard as distinctly over the body of the heart as at the aortic cartilage. The second sound is not accentuated, but is louder than the first. No murmur is heard at the back.

These signs were taken to indicate, as far as they went, the existence of mitral obstruction, and to leave in doubt the opinion between aortic obstruction and mitral regurgitation.

20th.—Patient growing worse, though he showed every morning a marked remission of the symptoms. By percussion I found that the cardiac dulness was quite distinct at the third left interspace. On the 22d the patient died suddenly of cardiac failure. The dyspnœa had gradually increased, but there was no pulmonary œdema; the pulse, however, had been steadily failing. At the base of the thorax, posteriorly, evidences had been found of some pleuritic effusion.

There were no chills, and no cerebral or other

Digitized by Google

embolic symptoms. The following is the record of the temperature, pulse, and respiration.

September	16TH.		17TH.		18TH.		19TH.		20TH.		21ST.		22D.	
	M.	E.	M.	E.	M.	E.	M.	E.	M.	E.	M.	E.	M.	E.
Temperature	. . .	101.2°	98.2°	99.5°	97.6°	99.7	98.5°	101.6°	98.2	100.6	97.8°	. . .	94°	
Pulse	. . .	120	110	108	108	120	114	120	114	140	116	. . .	102	
Respiration	. . .	32	35	44	32	40	42	36	40	44	40	. . .	45	died.

Post-mortem made fourteen hours after death. *Thorax:* Both pleural cavities contained some passive effusion. There was very little congestion of the lungs. *Heart:* There was a slight increase of pericardial fluid. The heart weighed sixteen ounces and a half. The increase of volume affected almost exclusively the left side, both auricle and ventricle. The muscle was of good color, but flabby. The right ventricle contained a large buff-colored clot which extended into the auricle and pulmonary artery. The tricuspid and pulmonary valves were healthy, and the right ventricle was but little dilated, if any. Its wall measured nearly one-quarter of an inch in thickness. The left ventricle contained a similar clot, smaller in size, and, in some places, still blood-colored; it extended into the auricle, the aorta, and coronary arteries, but was not unusually adherent. The left ventricle was dilated, and its wall measured five-eighths of an inch in thickness. The anterior leaflet of the mitral valve was somewhat thickened at the base, but its border was apparently healthy. The border of the posterior flaps was slightly thickened, and the valve did not appear sufficient to close the enlarged auriculo-ventricular opening in the dead heart, but was probably competent during the systole.

The aortic valve was the seat of the principal lesion —an extensive ulcerative endocarditis.[1] The left flap had its internal or right half completely destroyed, so that the external half hung from the outer portion of its line of insertion only. The right flap hung loose at both ends—that is, both extremities of the leaflet were destroyed, and what little was left of the border was thickened, ragged, and soft. The ulcerative process which destroyed the line of union of the right and left leaflets, extended on to the wall of the aorta, involving the inner half of the left sinus of Valsalva up to the mouth of the corresponding coronary artery. The right sinus was free from ulceration, but its valve, as stated above, was the one most seriously involved. A shred of this valve, still holding by its base, lay over, and was slightly adherent to the posterior or intercoronary leaflet. The latter was the most complete of the three, but was perforated near its right extremity, and almost, if not completely so, about the middle near the border. All the torn and ulcerated surfaces were very ragged, and the tissues concerned were quite soft. These surfaces had a reddish-gray color, with here and there a dark spot, apparently of clotted blood, especially in the last-named leaflet. The ulcers were not covered with distinct vegetations. On the ventricular aspect of the semilunar valves, and on the anterior wall of the left ventricle, for a short distance down from the aortic ring, a few warty vegetations, not larger than a pin's head, were found firmly attached to an otherwise apparently healthy endocardium. The arch of the aorta was slightly thickened, and some whitish mottling of atheroma was discoverable through the endothelium. The *spleen* was double the normal size. Its consistency was increased, and the capsule was thickened. The color was rather light and grayish. The trabeculæ were prominent. There were no embolic infarctions. The *liver* was of normal size, but its surface, especially towards the anterior border, was marbled by depressed and grayish contracting acini. The capsule of the *kidney* was slightly adherent, and the glandular structure somewhat indurated. Each kidney contained two urinary cysts, but no embolic infarctions.

This case was supposed to be one of chronic valvular disease with malarial cachexia, and rapid breaking down of the compensatory hypertrophies. It turned out to be one of acute malignant endocarditis, superinduced by malaria in the course of a chronic valvulitis. In the paper of Dr. Osler,[1] these two, malaria and chronic valvulitis, are considered amongst the etiological factors of malignant endocarditis, and they were both present in my case. As to the chronic valvulitis, the autopsy gives unmistakable evidence of its existence. There is no doubt that the man had aortic incompetency for some time previous to this attack; that the train of changes attendant upon this lesion was gradually developing; and that the absence of subjective symptoms, previous to this attack, was due to the compensatory hypertrophy and dilatation of the left ventricle.

In regard to the acute process which thus brought to a speedy and fatal termination the other more chronic changes, our knowledge is far from complete. A certain number of cases are being separated by pathologists from the group of acute endocarditis, and a subsection is being built up, which is designated malignant endocarditis; but the line of demarcation is not yet quite clear. I do not know that it has been determined whether the group is to stand on etiological or anatomical grounds. The etiological question involves the study of certain microörganisms which have been found in connection with the endocardial lesions. Anatomically the lesions of acute endocarditis are divided into ulcerative, vegetative, suppurative, and sclerotic. It is true

[1] In describing the aortic flaps I shall follow that nomenclature which designates two of them, anterior, one of which belongs to the right sinus from which the right coronary artery springs, and is called the right flap; the other belongs to the left sinus, from which the left coronary artery springs, and is designated the left flap. The third is termed posterior, or, better still, intercoronary, because its sinus gives origin to no coronary artery, and lies, of course, between the other two. By adopting this nomenclature, I do not mean to accept it as the most accurate, but it appears to me to be the most convenient for clinical purposes. As to its anatomical accuracy, it may be said of it, that it has the support of the older anatomists, and of Henle, and others, amongst the the moderns. The opposite view is ably defended by Sibson in Reynolds's *System of Medicine*. It is to be hoped that one or the other will be definitely adopted, to avoid confusion.

[1] Gulstonian Lectures on Malignant Endocarditis, by William Osler, M.D., THE MEDICAL NEWS, March 21, 1885.

Digitized by Google

that the latter is a chronic form, but there may be peculiarities in the acute process which lay the foundation for sclerotic changes subsequently. The specimens from my two cases illustrate the vegetative and the ulcerative forms.

I proceed now to analyze the physical signs of Case II. They demonstrate the existence of a dynamic auricular systolic murmur.

I shall dismiss, first, a consideration of the second sound, which was evidently produced in the pulmonary valve; and, secondly, I shall dismiss the feeble ventricular systolic murmur by stating that there was nothing found in the necropsy to warrant the opinion that the murmur was mitral regurgitant; I conclude, therefore, that it was aortic systolic.

The diastolic murmur deserves more study. I have just mentioned the feeble ventricular systolic murmur. Now, if the ventricle was capable of producing only a feeble murmur when driving a large volume of blood forwards over the inequalities of the aortic opening, we should not be surprised to find that the arterial systole would fail to produce any murmur when driving only a portion of that blood back into the ventricle. And that it did fail to produce any audible bruit, is shown by the physical signs, for I believe it will be admitted that there was no aortic regurgitant murmur. The reason for this may be further enlarged upon thus: The communication backwards and forwards between ventricle and artery was so free, the difference of blood pressure between the two localities was so little, that the velocity of the backward current towards a ventricle which never emptied itself completely, was not sufficient to produce a murmur. The murmur was then, as indicated by the physical signs, an auricular systolic murmur, occupying the whole of the diastole, and presenting a presystolic accentuation at the end. How was this murmur produced? Let us consider the position of the mitral valve during the diastole in this particular case. The breakwater of the aortic valve had been removed, and the mitral valve was shut down by the recoil of the arterial pressure. The bicuspid, in other words, did the work of the semilunar valves, and kept the reflux of blood from rushing back from the efferent to the afferent cavities of the heart. The mitral valve was closed, therefore, and the blood driven through its long chink by the hypertrophied auricle, produced the diastolic presystolic murmur. This murmur was heard along the ventricular borders, because the sonorous current was not directed straight against the apex as in organic stenosis, but was driven between the chordæ tendineæ, in a direction radiating towards the borders of the ventricle.

It is stated in the notes that the murmur was undulatory. My recollection on this point is not quite clear, and, indeed, I suppose that at the bedside it would have been difficult to determine whether the phenomenon belonged to the whole cycle—that is, whether it was produced by the different elements of the continuous murmur described, or whether it belonged to the diastolic presystolic only. However, it occurs to me, that if the heart were beating slowly this undulatory character should be noticeable in all mitral direct murmurs produced in the manner I have described. This attribute would be an expression of the oscillatory movements of the arterial pressure.

I find in Dr. Flint's treatise[1] the only distinct recognition of the existence of this mitral functional stenosis with which I have met. The same mechanism is evidently referred to in the account of Case 112, in Hayden's treatise on the *Diseases of the Heart*. But it seems to me that its importance must have been overlooked, and I take it that it should be recognized as an important element of prognosis in cases of aortic insufficiency. I believe the murmur in question is frequently present in cases of the latter disease, and that it accounts to a great extent for the transmission downwards of aortic regurgitant murmurs. It is a soft murmur without marked individuality as to quality, and often does not appear as a distinct murmur, but becomes consonant with the aortic regurgitant, intensifies it, and makes it more clearly audible at the apex, and ensiform cartilage than it would be otherwise.

Dr. Balthazar Foster, it appears, has demonstrated that when the posterior or intercoronary leaflet of the aortic valve is defective, then the aortic regurgitant murmur is transmitted towards the apex, because the recoil current, in such cases, trends that way. But I believe the fact to be that in such cases the regurgitant murmur is more apt to press directly upon and close the mitral valve, thereby giving rise to the auricular systolic murmur, which, as I have said, contributes greatly to the extension downwards of aortic murmurs. Whatever the explanation, the point as to diagnosis seems to be well taken; but not so as to prognosis. For Dr. Foster further maintains, that in such cases the prognosis should be more favorable, because that leaflet is affected which is not concerned directly in aiding the coronary circulation. In other words, he argues that the cardiac nutrition is better kept up than when the right or left leaflet is affected; these latter being instrumental in directing the stream of blood into the corresponding coronaries. But I hold with Dr. C. Hilton Fagge,[2] that the prognosis is rather more unfavorable in cases in which the murmur is transmitted towards the apex; and one of the reasons it appears to me now, is that the functional mitral stenosis is apt to develop earlier in these cases; and this functional mitral obstruction is the first halt or backward step of the blood current, from the ventricular or arterial side to the auricular or venous side, the first step leading down the steep to venous stasis, asystole, and death.

Let us not say then with Fothergill: "The day of the prominence given to the presystolic murmur will ere long be over," but on the contrary let us be watchful and studious of its import as seen in this new light.

Let us not make light of dynamic murmurs. Walsh leads us astray when he states that they differ from organic murmurs, in that the latter are attended with

[1] A practical treatise on Diseases of the Heart, by Austin Flint, M.D., page 207, second edition. Consult also an article on Cardiac Murmurs, in The Amer. Jour. of Med. Sciences for June, 1862, by the same author.

[2] Article on diseases of the valves of the heart, in Reynolds's System of Medicine, vol. iv. page 645.

Digitized by Google

other symptoms of cardiac disturbance, and alterations in size of the heart. This is incorrect. Many dynamic murmurs are accompanied with such concomitant alterations, due, it is true, to disease elsewhere in cardiac mechanism; but the murmurs are, nevertheless, indicative of conditions which aggravate the coexisting lesions.

Together with the auricular systolic murmur that I have been describing, we should have dilatation and hypertrophy of the left side of the heart, accentuation of the second pulmonary sound, and a feeble first sound. A complete absence of the first sound has been observed in some cases of aortic incompetency, in which the mitral valve was subsequently found healthy. These cases have been used as arguments against the valvular theory of the first sound. But if we consider that, under the circumstances in question, the ventricular systole finds the mitral valve already stretched by the arterial reflux, we can understand how their further closure at the moment of the systole may be noiseless, so far as the left ventricle is concerned: a feeble systole of the right ventricle will account for the absence of the tricuspid element.

It is easy also to conceive how this premature tension of the mitral valve may give rise to more than one form of reduplication of the heart sounds.

I have stated that this functional stenosis is a backward step; that it may be the first step towards cardiac impotency; but I must add that, like all other retrograde movements of the heart's cycle in disease, this one also comes under the following law of cardiac pathology, namely: That there is no step tending to cardiac impotency, which may not be at some time, or within certain limits, compensatory and salutary. The functional obstruction at the mitral valve, for instance, stands as a sentinel, keeping the amount of blood that comes from the auricle within the limits of the capacity of the over-distended ventricle.

Since writing the above report I have met with the following case of simple primary endocarditis. Such has been my diagnosis, and I present, without comments, the facts in the case. As a matter of interest concerning the etiology of these cases, I should mention that there has been an epidemic of mild scarlatina prevailing in this city since the end of July.

CASE III.—Joe R., 20 years of age, a sailor, born in Germany. His father is a robust sailor, but is occasionally troubled with stiff joints and subacute rheumatic pains. The mother died of acute pneumonia. He has six brothers and sisters, all healthy. He had the Asiatic cholera when one year old, and an attack of pleurisy at the age of eleven. This disease did not last over a week. To all other questions which may suggest themselves to the reader concerning the previous health of the patient, his invariable answer is that he has always been healthy. He is not subject to colds, and has rarely had epistaxis. He is temperate, and has never had any venereal disease. He is a well-developed, intelligent young German, with a florid complexion, and a slight excess of fat. He has good teeth, and large bones in the extremities. The chest shows some transverse constriction, with depression of lower portion of the sternum.

He has been employed for some time on steamboats and in stores about Jacksonville, Florida. About four weeks before taking sick he had returned from a short visit to Germany. About the first of this October he began to work in cleaning up the building of a German Club. His feet were wet nearly all day, and he slept in a damp basement room. He was taken sick on the 13th with severe headache. This persisted, and was accompanied with pain across the epigastrium, some nausea, loss of appetite, and slight aching of the limbs. He continued his work until the morning of the 16th, when he had a severe chill. After this he went out to get a dose of oil, which he took, and, on his return, went to bed with high fever.

October 17. Evening.—He was first seen by Dr. J. J. Edwards. The bowels were loose, the abdomen was tender, the tongue quite coated, the fever high, and suspicions of typhoid fever were entertained. Pulse 112; respirations 30; temp. 103.8° F.

18th. Morning.—I was asked to see the case with Dr. Edwards. I was struck, first, by the anxious expression, the slight icteric hue of the pale skin, and the excited action of the heart, which was observable over the shirt. The apex beat was found in the fifth interspace, just inside of the line of the nipple. The impulse was vigorous, sustained, slightly tremulous, and its area was wider than normal. There was a soft diastolic murmur, which was best heard about the middle of the sternum, and which was undoubtedly an aortic regurgitant murmur. The first sound was also murmurish, but this I attributed to the excited action of the heart.

The patient's mind was clear. His face flushed some as he spoke. He complained of no pain, except that across the upper segment of the abdomen. It was not a severe pain, but more a feeling of distress. The abdominal walls were sensitive, especially towards the iliac fossa. There was no pain in the limbs, no cough, no sore throat, no abnormal respiratory sounds. The skin was dry, and its papillæ were very prominent. He had vomited once. The stool passed in the morning was liquid, and light colored. The tongue was covered with a thick grayish coating; pulse 120, respirations 25, temp. 105.4°. He was sent to the Marine Ward in the City Hospital. I ordered him gtt. xv of tincture of the chloride of iron every two hours. In the evening his condition was the same, except that the temperature had commenced to fall. He was given gtt. xx of tincture of digitalis at seven o'clock P. M., and at midnight. The iron was continued, and orders given to substitute quinine for it if the temperature fell below 102°. Pulse 122, temp. 104.4°.

19th.—The temperature at two o'clock A. M. was 99.8°, and he was given gr. x of quinine at two, at three, and at four A. M. The temperature at four was 99.6°; at six it was 99°, and the pulse 86; at eight, pulse 86, respiration 15, temp. 99.2°. He has slept none; feels better; still complains of distress across the epigastrium. He had some headache. The face is somewhat flushed; the eyes are watery, and the lids puffy. With the heart beating 87, and the patient in the recumbent posture, the following physical signs are observed: The tremulous

Digitized by Google

character of the impulse, which yesterday amounted almost to a thrill, is better described to-day as a lingering of the heart in its position against the chest-walls. The position of the apex is the same. The area of cardiac dulness commences at the fourth left rib, and is in other respects also normal. The second sound is quite feeble on both sides of the sternum, and is accompanied and followed by a soft murmur, which is better heard at the third left space than at the second right, and still better over the sternum in an oblique line between those two points. It loses in intensity when it is followed down the sternum, and is lost; but it seems to increase when followed towards the apex, where (and even before reaching it) the murmur changes completely in character, and becomes rougher and longer, filling up the whole of the period of silence, and showing a presystolic accentuation. The first period is quite loud, and free from murmur. The pulse is rather small, easily compressed, and rapidly collapsing—a pulse of aortic regurgitation, without hypertrophy. The urine contains no albumen. The iron to be continued. Evening: No change in his general condition. Pulse 86; temp. 100.5°.

20th.—Has taken this morning gr. v of quinine at six, seven, eight, and nine o'clock. The iron continued. Pulse 90; temp. 100.8°. The epigastric distress was much relieved after vomiting some greenish fluid this morning. The tongue is thickly coated in the back and centre. Near the edges there is a belt with a sharp outline of a much lighter coating. The face is less flushed. The pulse is larger and more jerking, but still receding. The icteric hue is very faint. The pulse of the carotids and subclavians is visible. Has had two liquid stools in the twenty-four hours. The two murmurs are to-day more easily separable, and I am convinced of the existence of the two lesions, aortic insufficiency and mitral stenosis. In the evening complains of headache and restlessness. Pulse 82; temp. 102°. He is ordered gtt. xx of tincture of digitalis at eight P. M. and at two A. M. Is to take also gr. x of quinine at four, six, and eight A. M. to-morrow.

21st.—The quinine has been taken, and the iron is continued. Pulse 86; temp. 101.4°. Very little sleep, but feels much better. The tongue is cleaner. The bowels have not been moved. The urine is decidedly acid, and of a light orange color. It has a specific gravity of 1.023. It contains no albumen, and presents nothing abnormal on microscopic examination. The cardiac area of impaired resonance commences at the third rib. The second sound is more pronounced at the left than the right border of the sternum. The murmur of the second sound is very soft, and is rapidly lost in all directions from the left half of the sternum, at the level of the third interspace. The presystolic murmur is becoming rougher. Evening: Pulse 70; temp. 100°.

22d.—Pulse 64; temp. 98.2°; xx gr. of quinine in the morning, and the iron continued every two hours. Evening: Pulse 62; temp. 98.2°.

23d.—Morning: Pulse 60; temp. 97.5°. Evening: Pulse 58; temp. 98°.

24th.—Morning: Pulse 50; temp. 97°. Evening: Pulse 56; temp. 97.5°.

For the use of the tincture of iron I have no better reason to give than this: I use it with success in cases of erysipelas and diphtheria; and I thought that, perhaps, it would tend to consolidate the coagula, and thereby prevent embolism. This suggestion I received some years ago from Dr. J. L. Ludlow, of Philadelphia, as appropriate to the treatment of embolism in general, rather than that treatment which aims at dissolving the coagula.

27th.—The favorable condition continues. The quinine has been discontinued. The treatment now consists of rest in the horizontal position, and iron three times a day. I shall watch the development of the cardiac hypertrophy.

CHARLESTON, October 27, 1885.

AN UNUSUAL CASE OF PHARYNGEAL FISTULA.

BY HOBART A. HARE, M.D.,
PHYSICIAN TO THE CHILDREN'S DISPENSARY OF THE UNIVERSITY HOSPITAL.

THROUGH the kindness of Dr. W. E. Hughes, I am able to report this case, which is a curious one for several reasons, which will become apparent when the following history is read.

CASE.—A. E., æt. 5 years. Boy. Came to the dispensary of the Children's Hospital with the history that he had fallen on his head from a chair about two years ago, and that this accident was soon followed by disease of the cervical vertebræ, which at present has resulted in fixation of the head to a great extent. Four months ago he was taken to the orthopædic dispensary of the University Hospital for this fixation, which seems to have caused the mother considerable alarm. Soon after this the mother noticed a slight puffiness on the right side of the neck near the sterno-mastoid muscle, and within a few days there was a sudden discharge of pus from the mouth. The swelling at the side of the neck increased in size, and finally opened of itself with a considerable escape of pus.

No sooner had the pus begun to stop than the mother noticed that a portion of the food which he swallowed frequently escaped through this opening in the neck. She states that this escape of food is not constant, but occurs only at varied intervals, and from a series of cross-questions it seems probable that the fistulous tract is at least partially closed on certain days by granulations, which at other times are destroyed by some motion of the head, thereby making the tract again patulous.

At the time that I examined the boy the mother stated that no food had escaped through the fistula for several days, and a drink of water taken at my direction passed safely down without any part of it appearing at the external opening. A rough examination of the larynx with the aid of an ordinary tongue-depressor, the only instrument I had at hand, revealed nothing, probably because the internal opening was too low down to be seen without instrumental aid. At my request, she promised to take the child to the dispensary for the diseases of the throat and nose at the University Hospital on the next day, in order that a thorough examination might be made. Unfortunately, the next day was stormy and she did not appear. I was also unfortunate enough to mis-

Digitized by Google

lay her address, so that I am unable to give a more thorough description of this unique case.

Although many standard works on diseases of this portion of the body were consulted, the writer was unable to find any account of a similar condition to the one before us. Many of these works mentioned congenital and traumatic fistulous openings of the pharynx or œsophagus, while others mentioned the formation and subsequent rupture into the pharynx of abscesses associated with disease of the cervical vertebræ, but none of them had any record of pharyngeal or œsophageal fistula following cervical caries.

This case seems to the writer to be of interest for the following reasons:

First. Its origin from cervical disease, produced by a fall.

Second. The entire absence of any sign of congenital fistula, generally known as bronchial fistula.

Third. The almost simultaneous rupture of the abscess into the pharynx or œsophagus, and on the side of the neck.

Fourth. The unusual position of the external opening, viz., under the sterno-mastoid muscle, instead of near the thyroid cartilage, which is the common region for the external opening in these fistules.

Last, but not least, it is an interesting point that the pus should have escaped into the pharynx while the child was awake, since the presence of an abscess in that region was not thought of, and no precautions against suffocation during sleep were taken.

The position of the external opening, only about one and one-half inches below the angle of the jaw, seems to me to point to the abscess being post-pharyngeal, rather than post-œsophageal, since the food would hardly pass outwards and *upwards*, even if propelled by considerable movement of the muscles of the neck, which, in this case, is very unlikely owing to the fixation of the head on the trunk by the cervical disease. The opinion that the internal opening is pharyngeal gains strength when the fact is remembered that the escape of food is almost simultaneous with the act of digestion, which would be an impossible occurrence if any muscular movement was required to force the food upwards.

NOTE.—Since writing the above, Dr. Reeves informs me that the patient was eventually taken to him at the University as requested, and that a very thorough examination of the pharynx with the laryngoscope failed to discover any internal opening in that region. As *all* the former symptoms continue, and as the child is failing fast owing to septic poisoning, and the disorder of digestion consequent on swallowing large quantities of pus, the writer believes with Dr. Reeves that the internal opening must be in the œsophagus.

GANGRENE OF THE SCROTUM FOLLOWING EXCISION OF THE INGUINAL GLANDS; AN ACUTE REFLEX TROPHIC LESION.

BY W. B. PLATT, F.R.C.S. (ENG.),
OF BALTIMORE.

I WISH to call attention to the occurrence of localized gangrene of the scrotum after the excision or scraping out of enlarged inguinal glands, and to express my belief that when this takes place it is due to a definite lesion of trophic nerves.

Two cases of gangrene of the bottom of the scrotum following excision of the inguinal glands, have come under my immediate observation, and Dr. Tiffany kindly gives me notes of his own case in which this occurred, making three altogether.

CASE I.—While House Surgeon in the Boston City Hospital in September, 1879, an Irishman, æt. about 40, was admitted, suffering with chronically indurated inguinal glands in the left groin of two years' standing. They had never suppurated, and caused inconvenience only by their size and occasional pain felt in them. There was no evidence of secondary syphilis, and no history of a skin eruption. The patient said he had a sore (probably a chancroid) a short time previous to the glandular swelling. At the time of the operation he had, however, a small indurated lump on the preputial margin, as large as half a peanut-kernel. This had existed but a short time. The man was tremulous, suffering from chronic alcoholism. In the left inguinal region was felt a hard, oval, immovable mass, about two and a half inches in its long diameter. The skin was slightly reddened over it. The patient being etherized, Dr. Geo. Gay made an incision in the long axis of the swelling, parallel to Poupart's ligament, and removed two connected lumps the size of pigeon's eggs. On section these were seen to be gray, with numerous yellow foci, the size of canary seeds, scattered throughout their substance. The wound was brought together by sutures, a drainage-tube left in, and carbolic gauze dressings applied.

The entire operation was done under strict antiseptic precautions. Elastic webbing was applied over all to retain the dressings in place. The wound itself healed with little redness, swelling, or discharge.

The only noteworthy fact in this connection is that the bottom of the scrotum on the left side became swollen and red on the second day; on the third and fourth days an oval, sharply defined dark patch, one and a half to two inches long, was to be seen at this place. This eventually sloughed away with considerable discharge of pus, and the resulting gap healed rapidly by granulation. The erythema of the scrotum extended to the antiseptic dressings, but not under them.

CASE II.—Patient was a young white male, at Bayview Hospital, Baltimore. When I came on duty the patient had been operated on, two weeks previously, by my predecessor, who had scraped out his inguinal glands on the left side, and had slit up the meatus urethræ. Within a few days after the operation on the glands, the bottom of the scrotum became red, swollen, and tender. Two sharply defined dark patches appeared, one of which extended across the median line of the bottom of the scrotum. The sloughs were separated by a bridge of skin on the surface, although connected beneath. In removing them I withdrew a large part of *both* sloughs, by drawing upon one of them. The resulting gap healed well by granulation. In this case no attempt had been made to use antiseptics. The testicles were not exposed in either case.

CASE III.—Dr. Tiffany (to whom I mentioned my views last April) informs me that in the spring of

Digitized by Google

1884 he spooned out the enlarged inguinal glands in the right groin of a young male patient at Bayview Hospital, Baltimore. Several days later the scrotum at its lower portion became thickened, red, and painful, a large patch of the swollen tissues, four inches in diameter, speedily presented the appearance of gangrene, which extended somewhat beyond the median line. The slough soon separated, and the wound healed by granulation.

The only elements these three cases have in common are, the operation upon the inguinal glands, and the resulting gangrene of the bottom of the scrotum, with the usual attendants upon the process of repair.

In supposing such a relation as that of cause and effect, between excision (or scraping out) of the inguinal glands and gangrene of the scrotum, we may consider.

1. Phlegmonous erysipelas.

2. Gravitation of septic fluids, or direct extension of inflammation from the groin to the scrotum.

3. Interference with the circulation, by obstructing the free flow of blood to or from the part.

4. An acute reflex gangrene from intense irritation of trophic nerves.

1. Phlegmonous erysipelas is a loose term frequently applied to several other diseases. Simple cellulitis has often been so denominated.

I especially noted at the time of the first operation, that the redness did not begin at the *wound* but at the scrotum, as the healing of the wound in the inguinal region was quite normal in every way. The erythema did not even extend beneath the gauze dressings. The gangrene could not be attributed to the carbolic spray, since that was not employed in the two other parallel cases. The snipping of the meatus probably had no connection with the gangrene, since that was done only in Case II.

If by erysipelas we may understand inflammation, gangrene, or sloughing, then we agree to the term; there was no erysipelas elsewhere in the wards in Case I., and no other patients were affected, although dressed with the same instruments, and by the same persons as in the case in question; there was not a scratch on the spot of the scrotum where the lesion began in every case. In the other two cases there may have been erysipelas somewhere in the wards, since it is far from uncommon at Bayview, although I do not know of any. But in none of these cases did the erythema begin at the wound, but at the bottom of the scrotum; if this was erysipelas, why did the *wound* escape? why did the penis escape? where was the vesication so often seen in erysipelas, but in none of these cases? why did the inflammation remain so generally restricted to one side of the scrotum instead of invading it all? Mr. Liston[1] is quoted by Holmes, in his *System of Surgery*, as saying that "erysipelas of the scrotum may follow sores or eruptions, situated in the groins, genitals, or inside of the thighs, or in cases of fistulæ." In the latter it might follow by extension from them. The first examples can, however, be explained upon the same anatomical grounds as can our cases, if were are willing to call erythema, or dermatitis what Mr. Liston calls erysipelas.

2. Gravitation of septic fluids from the groin into the scrotal tissues, or extension of inflammation from the wound to the scrotum. The first of these suppositions assumes that there are septic fluids generated in the wound. Of this there was no evidence in any case, or that having them that they could gravitate in this way, or that having gravitated they would cause gangrene.

The ordinary inflammation of lymphatics is not prone to travel away from, but rather toward the trunk. We know that in extravasation of urine the fluid rises upon the penis, or upon the abdomen, but the groins are not invaded by the urine under the superficial fascia. We also know that quite extensive inflammation may occur in the scrotum from injury or from various causes without a resulting gangrene, although this last does occur at times apparently without sufficient cause being apparent. Why, therefore, should an operation four inches away cause gangrene when no direct connection between the wound and the gangrene, for inflammation or septic products, has been proved.

3. The inconsistency of some eminent authors, as well as the force of tradition, is well shown by Humphrey (Cambridge, Eng.), who states:[1] "The tissues of this region have no great degree of vitality, the arterial branches to it are long and delicate, and . . . . are thus easily strangulated;" while a little further we read, "The remarkable power of repair which the scrotal tissues possess . . . . is well known." The first part of the first quotation is pure assumption, while the second quotation is a fact we all admit. As a matter of anatomy, the scrotum is abundantly supplied with both vessels and nerves. The fact that the tissues are loose is absolutely no reason why they should be especially subject to gangrene. That some other tissues are dense and firm, has been advanced with more reason as a cause of the quick necrosis they undergo from strangulation of their bloodvessels.

4. An acute reflex trophic lesion due to irritation of the branches of the ilio-inguinal nerve of the groin and reflected to the terminal filaments in the scrotal tissues. It is well known that local reflex alterations of nutrition do occur from irritation of peripheral nerves—certain skin eruptions, as herpes. Some cases of acne and pemphigus clearly have this origin. Reflex œdema has been frequently observed, clinically, as well as produced in the physiological laboratory. Cases of gangrene due to reflected nervous influence have been observed by Sir William Ferguson,[2] Gubler,[3] and Grainger Stewart,[4] according to Brown-Séquard, who also states[5] that he has often seen gangrene of the ear produced by a mere prick of the medulla. He proceeds to say, "those persons who know that even gangrene may be caused by an influence of the nervous system, as rendered so probable by Dr. Ray-

Digitized by Google

naud,[1] will not be reluctant to admit that it may be the result of a reflex influence from irritated nerves."

We know that the region of the groin and the scrotal[2] tissues is supplied by branches of the same nerve-trunk, viz., the ilio-inguinal, and that a motor reflex connection exists between the skin branches of the genito-crural nerve and the cremaster muscle. We have no good evidence that the gangrene of the scrotum is produced by the other known causes of gangrene. These two nerves are complementary to each other. Knowing that a reflex gangrene has been observed elsewhere, a reasoning by exclusion and by analogy will lead us to believe it quite probable that gangrene of the scrotum, following excision, etc., of inguinal glands, is an acute reflex trophic lesion.

MEDICAL PROGRESS.

A CASE OF SUDDEN PULMONARY CONGESTION RELIEVED BY ASPIRATION OF THE AORTA.—DR. J. DACRE, in *The Bristol Medico-Chirurgical Journal* for September, 1885, reports a case of sudden pulmonary congestion, in which aspiration of the aorta, accidentally performed, instead of aspiration of the right auricle, as intended, was followed by immediate relief.

The patient had been suddenly seized with dyspnœa, and when first seen was gasping for breath, each inspiration rattling the mucus collected in the throat and larynx, and which he was too feeble to expel.

All efforts made to relieve his condition being without effect, and he being now *in extremis*, it was determined to aspirate the right auricle. With this intention, a medium-sized needle and canula was inserted in the fourth intercostal space on the right side, close to the edge of the sternum, passed straight through the intercostal tissue until it was felt to be in the chest, and pushed in that direction for about an inch and a half. On removing the needle blood jetted out of the canula, and in about five minutes thirty ounces of blood were withdrawn.

The needle was then removed, and no hemorrhage occurring through the puncture, it was at once sealed with collodion.

The condition of the patient at once improved, consciousness returned, he breathed more readily, and was able to speak.

The improvement was, however, only temporary, and the operation was again performed for the patient's relief, this time unsuccessfully, death occurring in about forty minutes.

Post-mortem examination showed that the aspirating needle had passed immediately above the right auricular appendix and had pierced the anterior surface of the aorta about one-quarter of an inch above one of the semilunar valves.

In reference to the best locality for puncture of the auricle, Dr. Dacre thinks the fourth interspace close to the sternum preferable, as in this position by experiments on the dead body, he has found that a needle passed directly backwards, almost invariably pierces the auricle.

[1] De l'Asphyxie Locale ou Gangrene Symétrique des Extrémités, Paris, 1862.

[2] The scrotum is supplied by the two external pudics, the superficial perineal and the cremasteric arteries, and by branches of the ilio-inguinal, pudic, and inferior pudendal nerves.

THE TREATMENT OF CHRONIC BLEPHARITIS.—PANAS recommends the following preparation in the treatment of chronic blepharitis:

℞.—Hydrargyri binoxidi. . . .	gr. ½.
Vaseline	℥ijss.
Liquor plumbi subacetatis . .	gtt. v.
Ft. unguent.	

S. Apply to the eyelids morning and evening, and during the day bathe the parts frequently with an aromatic astringent.—*L'Union Médicale*, October 17, 1885.

UTERUS DIDELPHYS OR DUPLEX (?), WITH A DOUBLE VAGINA.—LITSCHKUS, *Vratsch*, 1885, No. 26, reports the case of a woman, aged twenty-nine, who first menstruated at the age of eighteen; sometimes at intervals of two or three weeks, at others, after periods of a week. Some years previous to her coming under observation she had aborted.

Examination showed the external genitals to be normal. The vagina was divided by a partition wall into a right and a left space, the right being the larger, communication between which existed at the *os uteri* by a perforation in the partition. The right-sided portion of the vagina was free, while the left, besides being shorter, was adherent above and behind, so that only with difficulty could a speculum be introduced into it.

Both vaginal divisions could be recognized by rectal examination, and also through the abdominal wall; the furrow between the two horns of the uterus could be recognized. The sound, both on the right and the left side, entered the uterus to a depth of three and four-fifths inches. The menstrual flux appeared to escape from the right side only, the os uteri of which was smoother and softer than that of the left organ, which probably was without function.

Dr. Litschkus remarks on the rarity of the cases in which diagnosis of the condition is made during life, and refers to diversity of opinion in a case reported previously by Kubasov, as to whether the condition was that of uterus didelphys, or uterus duplex.—*Centralblatt für Gynakologie*, October 17, 1885

INDICATIONS FOR CHOLECYSTOTOMY.—DR. AUGUSTUS C. BERNAYS, after a discussion of cholecystotomy, appends the following conclusions in reference to the indications under which the operation should be performed.

1. The causes which indicate an operative interference with the system of gall vessels are: *a*, jaundice; *b*, paroxysmal pain or a tumor in the right hypochondriac region; *c*, suppuration; *d*, peritonitis; these conditions to be either severally or singly recognizable, the presumable origin being biliary calculi; *e*, malignant disease.

2. Explorative laparotomy must be preferred to acupuncture or aspiration as a diagnostic measure.

3. The incision in the linea alba is preferable when there is much doubt regarding the seat of obstruction, because the large ducts can be reached much better from this incision than from the incision parallel to the free border of the ribs.

Digitized by Google

4. The escape of bile through an abdominal fistula is not injurious to the process of normal digestion. The bile is an excretion, and probably of no more use in the intestinal canal than the urine in the bladder.

5. Jaundice, when caused by an obstruction of the common duct is no contraindication to natural cholecystotomy. We may often save life by its early performance.

6. Cholecystotomy, natural and ideal, and cholecystectomy are the three operations at our service; cholecystenterostomy may be useful, but it has not yet earned a place among approved surgical procedures.

7. Ideal cholecystotomy is indicated when the bladder is normal in structure and when the gall-ducts have been cleared of obstructing calculi.

8. Natural cholecystotomy is indicated when the bladder is ulcerated or suppurating, or when there are permanent obstructions beyond reach at the time of operation.

9. Cholecystectomy should be limited to cases of otherwise incurable or malignant disease of the gall-bladder.—*The Weekly Medical Review*, Oct. 31, 1885.

A CASE OF RIGHT-SIDED CHYLOTHORAX DUE TO TEARING OF THE THORACIC DUCT.—DR. KRABBEL reports the case of a youth, 16 years of age, in whom rupture of the thoracic duct was caused by his being run over by a wagon, and was followed by chylothorax. The patient was first seen by Dr. Krabbel the morning after the accident, and appeared not seriously injured, breathing without difficulty, and complaining only of pain in the region of the sternum, and on both sides of the thorax. The external wounds were extremely insignificant, and no ribs were broken; no emphysema. The patient, though with difficulty, was able to raise himself in bed.

Percussion on the right side revealed nothing abnormal, while on the left a dull zone two inches wide existed below the scapula, and in this region the vesicular murmur was absent. Temperature 97.3° F. Respiration 76. Diagnosis was made of contusion of the thorax, and right-sided hæmothorax, due to wounding of a vessel.

The condition of the patient remained favorable, with but little variation in his symptoms, until September 3d, when, though not so well, the patient, contrary to orders, left his bed to go to stool. The nights of September 4th and 5th the symptoms became urgent, and the patient suffered from thirst and coldness of the extremities, and breathing was difficult.

Examination, made the following morning, showed percussion dulness over the entire left lung, absence of respiratory murmur, and pectoral fremitus. The percussion râle in the right half of the thorax, before as well as behind, was plainly tympanitic. The symptoms gradually increasing in severity, the patient died, apparently of suffocation.

Post-mortem examination showed all the thoracic organs to be normal, but, strange to say, the ninth thoracic vertebra was found fractured diagonally, and in this location the thoracic duct was also cut through, but little difficulty being experienced in introducing a sound into the upper and lower fragments. The œsophagus, aorta, and vena azygos were entirely normal. The most singular fact of all is, that neither the dura mater nor the spinal cord itself presented the least sign of injury, neither had there been any symptoms of paralysis manifested.—*Centralblatt für Chirurgie*, October 17, 1885.

PHYSIOLOGICAL AND THERAPEUTIC EFFECTS OF PYRIDINE IN ASTHMA AND CARDIAC DISEASE.—M. GERMAIN SÉE, in a discussion of the therapeusis of asthma, gives the following review of the general effects of pyridine—reference to which has already been made in these columns.

The best method of administration is to pour sixty or seventy-five grains of pyridine in a saucer, placed in a small chamber containing about twenty-five cubic metres, the patient being seated in a corner of the room, and thus breathing air mingled with the vapor of the drug. The *séance* should last about twenty minutes, and be repeated three times daily. The absorption is immediate, the pyridine appearing almost at once in the urine.

a. The oppression diminishes considerably, respiration becomes free, desire for air less imperious, while the heart becomes calm and regular, and the pulse preserves its rhythm and force.

b. Toward the close or after the *séance* patients experience an irresistible tendency to sleep.

During slumber, there is a marked diminution of the reflexes with conservation of contractile power; which, however, is diminished. Neither paralysis nor convulsions are produced, neither is there evidence of tremor.

c. The action of pyridine should not be compared with that of chloroform or ether. It possesses the special property of diminishing bulbar and medullary reflex excitability; and in this connection it is remarkable that such effect is not found in like degree in nicotine and atropine, both of which contain pyridine.

d. The effect of pyridine upon respiration continues for some time, and the tendency to nocturnal oppression disappears as the result of inhalations practised during the day. Patients sleep well and desire the inhalations.

e. After two or three *séances* expectoration becomes more abundant and fluid, and loses its purulent and fetid character. Mucous râles alone are heard, and these finally disappear and respiration almost regains its normal sounds. The use of the drug is attended with no inconveniences, save perhaps a slight tendency to nausea and vertigo. In some cases attacks of suffocation disappear completely; in others the effect of the drug diminishes after eight or ten days, and it then becomes necessary to combine it with the iodides.—*Bulletin Général de Therapeutique*, October 15, 1885.

DISLOCATION OF BOTH HUMERI.—GÜTERBOCK (*Berliner klin. Wochenschrift*, No. 22, 1885) reports a case of double dislocation of the humerus, which, by reason of its rarity, is of extreme interest.

The patient, an old woman, aged 86, by a fall from bed dislocated both humeri, the head of the left being more internal to the coracoid process than that of the right, which, however, was replaced with more difficulty and only after anæsthesia.

Four weeks after the accident the patient died, and post-mortem examination showed complete cicatrization of the tear in the articular capsule on each side, the only signs of the injury being a reddish cicatrix and a thickening at the seat of the injury.—*Centralblatt für Chirurgie*, October 17, 1885.

LEPROSY: ITS NON-CONTAGIOUSNESS.—The following summary of the views of physicians in Japan—as ascertained by PROF. VIRCHOW—in relation to the contagion of leprosy, is of much interest.

1. The hereditary tendency of the disease should be considered as proven; sometimes a generation escapes.

2. Infection does not occur either by marriage or by sexual intercourse.

3. No instance of a well-established case of direct contagion is known.

4. In Japan, there are no leper communities, no hospitals, further than hygienic proscriptions or ordinances relating to lepers.—*Gazette Hebdomadaire*, Oct. 16, 1885.

EPILEPSY AND HEMICRANIA.—B. SILVA (*Giornale di Neuropatologia*, Fasc. 1 and 2, 1885), in discussing the relations of epilepsy and hemicrania, while recognizing the frequency of heredity in both, calls attention to the following points of difference between the two diseases:

1. While hemicrania in the great majority of cases begins about the period of puberty, epilepsy most frequently begins at the end of childhood.

2. The attacks of hemicrania become less frequent and less intense with advancing age, and in old age often cease entirely—while, on the contrary, epileptics commonly terminate life insane.

3. That occasional causes—menstruation, mental excitement, etc., exert a greater influence in the production of hemicrania than of epilepsy. Silva's views agree essentially with those of Wagner and Struempell, who are among those who deny the essential relation between the two diseases, for the reason that the attacks in the two diseases are not similar.—*Rivista Internazionale di Medicina e Chirurgia*, September, 1885.

THE USE OF IODOL IN SURGICAL OPERATIONS.—DR. GÆTANO MAZZONI calls attention to a new chemical preparation, called Iodol. The substance is a powder of a yellow or grayish-brown color, nearly odorless and perfectly tasteless, and has an action very similar to that of iodoform.

The observations made upon its effects already exceed two hundred, and the results have been extremely favorable.

The remedy may be used in powder, suspended in glycerine as an ointment, or in dilute solution of alcohol and glycerine, the substance being entirely insoluble in water.

In venereal disease its effects have been excellent, as also in periadenitis.

In abscesses, in which necrobiosis is extensive, the beneficial effect of iodol is manifested in the disappearance of all odor and the rapid disappearance of swelling and accompanying healthy granulations.

In indolent ulcers a similar beneficial influence was noted.

On the other hand, the remedy is found useless and indeed harmful in gangrene.

Further, it is found to possess the power in a high degree of promoting healthy granulations, as is shown by its use in various forms of lupus and in chronic fungoid inflammation of the joints. The chemical formula of the preparation is not announced in the article calling attention to its merits.—*Berliner klin. Wochenschrift.* October 26, 1885.

SPINAL TUMORS IN CHILDREN.—At the recent meeting of the German Society of Scientists and Physicians, held at Strassburg, HERR KOHTS reported four cases in which tumors of the spinal cord had occurred in children under his observation.

The first case was that of a boy fifteen years old, who for a long time suffered severe pain in the right arm, together with loss of sensibility (and strength) in the member, finally progressing to complete paraplegia and terminating in death.

Post-mortem examination revealed the presence of a very soft sarcoma in the cervical portion of the spinal cord.

The second case was that of a little girl one and a half years of age, of extremely tuberculous parents, who developed in the course of a basilar tubercular meningitis a special sensibility of the vertebræ and a monoplegic paralysis of the left lower extremity. Post-mortem examination in this case showed the presence of tubercle in the thoracic portion of the cord.

In the third case an attack of intermittent fever supervened upon scarlatina. No paralysis occurred, but death followed, with symptoms of meningitis, and tubercle was found in the lower thoracic portion of the cord.

In the fourth case was manifested paralysis of the lower extremities, together with greatly exaggerated reflex excitability, and fistulæ were established proceeding from the vertebræ.

Autopsy showed the presence of caseous foci in the spinal cord.—*Berliner klin. Wochenschrift*, October 26, 1885.

INJURIES OF THE MAIN BLOODVESSELS IN THE AXILLA CAUSED BY EFFORTS TO REDUCE DISLOCATIONS OF THE SHOULDER.—DR. LEWIS A. STIMSON, in a discussion of the injury of the axillar vessels in efforts to reduce dislocation, says: An important question arises in connection with the treatment of dislocation of the shoulder: How far does the possibility of the occurrence of this accident affect the choice of a method of reduction? and also concerning the propriety of attempting reduction in cases that are not recent.

In the reduction of recent dislocations, these accidents show that abduction of the arm especially should be avoided, as also circumduction, violent traction, and rough pressure in the axilla. Kocher's method by manipulation appears well adapted to avoid the danger. It is also to be remembered that the injury to the vessel may be caused by the dislocation itself, and its symptoms may be masked by the swelling commonly present during the first few days.

In old dislocations the probability of the occurrence of the accident is increased by the more forcible measures usually necessary to break up the adhesions that bind the bones in their new relations; and, while it may be proper in many cases to make the attempt to restore the limb to usefulness, this possibility creates another reason for abstention when the patient is old, the duration of the dislocation long, and the adhesion firm. Even a dislocated arm may be very useful, and the fatality of this accident—more than 70 per cent. of deaths, may well cause the surgeon to hesitate to incur the risk merely for the sake of ameliorating a condition which does not endanger life and is quite compatible with activity and usefulness.—*Annals of Surgery*, Nov. 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, NOVEMBER 14, 1885.

COMPRESSION OF THE BRAIN.

MORE than a hundred years ago Saucerotte, while studying the theory of *contre-coup*, was so much impressed with the idea that the brain must be incompressible, as to announce, as one of the modes of fracture by counter-stroke, that a blow on one side of the head might drive forward against its opposite side a column of brain-mass, which would act like a solid body. On the other hand, Adamkiewicz has recently asserted that the brain is compressible, his opinion resting upon the observation that the introduction of a laminaria tent within the skull causes depressions on the surface of the brain. This view, however, is diametrically opposed to the commonly accepted theory in regard to the *rationale* of the symptoms of compression of the brain; and its publication has given rise to a recent paper by VON BERGMANN, in the *Archiv f. klin. Chir.*, Bd. xxxii. Heft 3, in which he comes to the rescue of the theory which he had before advocated in his work on injuries of the head. This theory, it will be remembered, refers the symptoms of compression of the brain to irritation and paralysis of the centres for the pneumogastric and vaso-motor nerves, due to anæmia, caused by pressure upon the capillaries, transmitted from a distant part of the cranium.

This theory rests upon the fact that the brain is incompressible, and that pressure upon any part of it will be conveyed through it. so that its effects will extend to every part, while the predominance of the symptoms of irritation in the centres of the vagus and vaso-motor nerves depends solely upon their relative sensitiveness. The practical importance of the theory is indicated by the fact that WIESMANN, in a paper published in the *Deutsche Zeitscrift f. Chir.*, 1884, Bd. xxi., has collected twenty-two cases, in which reliance upon it has led to trephining, to the removal of a clot, and, in twenty of the cases, to recovery of the patient. In view of these statistics, it is no wonder that Bergmann reiterates the correctness of his theory, and expresses great surprise that Adamkiewicz should have mistaken the phenomenon of mere displacement of the fluid contained in the brain for an evidence of its compressibility. Nor can we see how he could have confounded the effect of the enlargement of a laminaria tent by a slow imbibition of fluid drawn from the succulent tissues nearest to it with that produced by blood escaping rapidly from the vessels, and driven on by the muscular force of the heart and arteries. The fact is, that the juices of the brain may, with tolerable ease, be drawn out, or driven out, of it; but the brain is not compressible in the true sense of this term. It may not be quite so incompressible as Bergmann thinks, who says it must stand between water, which is compressible only forty-six parts in a million, and glass, which is compressible only one part in a million. But that it is incompressible, except by a slow process of displacement of its fluid parts, and acts like an incompressible fluid under certain circumstances, is shown by recent experiments in Germany, in which the skull has been burst by the sudden rise of intracranial hydrostatic pressure, caused by the impact of a projectile travelling with great velocity.

And here we touch the keynote of von Bergmann's article. It is, that increase of intracranial pressure will cause anæmia of the brain, by compressing the capillaries, a very slight reduction in the size of which results in cutting off a large proportion of the blood-current. In 1880 Bergmann directed a series of experiments by Bastgen, in which an artificial anæmia was produced by injecting an emulsion of oil into the distal end of the carotid artery. The effect was typical, as shown, first, by slowing of the pulse, due to irritation of the vagi, and by increase of the blood-pressure, due to irritation of the vasomotor centre; and, secondly, by a reversal of these conditions, due to the succeeding paralysis of both of these centres.

Von Bergmann's interpretation of these experiments seems to be confirmed by the investigations of Naunyn and Schreiber, who found that symptoms of compression of the brain are produced by less elevation of the intracranial pressure, if the blood-current has been previously diminished by compression of the carotid arteries; while it requires a much greater elevation of the intracranial pressure to produce similiar symptoms if the blood pressure in the cranium has been increased by compression of the abdominal aorta. Usually the pressure in the subarachnoid

Digitized by Google

space in the spinal cord and brain is nearly the same as that in the capillaries, as has been demonstrated by the experiments of Landerer, and confirmed by those of von Bergmann. This, and the effect of raising the intracranial pressure, the latter surgeon has recently exhibited in a child fifteen months old, from whom he removed a meningocele larger than a man's fist. In this case he produced restlessness, cries, turning up of the eyeballs, drowsiness, and Cheyne-Stokes respiration by pressure upon the tumor. It seems clear that the pressure upon the tumor increased the intracranial pressure, from the fact that pressure upon the open fontanelle raised the pressure in the tumor itself. All this furnishes strong support to the theory of compression of the brain which we have stated above.

This theory receives further confirmation from the results of certain experiments of von Schultén, made in studying the same subject, from the standpoint of the changes in the bloodvessels of the fundus of the eye. These experiments are described, and the author's deductions from them are given in a series of valuable articles published in Langenbeck's *Archiv* of this year, the last of which has not yet appeared. We regret that we have not space to more than allude to them, and to the interesting observation which they confirm, that an increase of intracranial pressure is accompanied by an increase of pressure within the sheath of the optic nerve. The result of this is a diminution in the calibre of the arteries of the retina, and an engorgement of the veins, as evinced by the choked disk. An interesting case in which this phenomenon has been observed is now in a hospital in this city. The patient is believed to have an effusion of blood within the skull, due to a fall or blow, and his eye ground shows the very phenomena which von Schultén describes. A systematic examination of the fundus of the eye in cases of injury of the head would furnish, we believe, a valuable complement to the experimental researches which we have mentioned. This is a matter which we would commend to the attention of surgeons who see a large number of such injuries.

PASTEUR ON HYDROPHOBIA.

SINCE the Copenhagen Congress, we have not heard any confirmatory evidence for the statements then made by PASTEUR that he had discovered a cure for hydrophobia, but at a recent meeting of the Paris Academy of Medicine a further, and most important communication was made by him, which, if substantiated, will prove one of the most valuable discoveries of the century. On this occasion he announced that he had, by a series of successful inoculations, cured a case of human rabies.

Briefly stated, the facts are these: He had previously, by vaccinations, rendered dogs insusceptible to the poison, and obtained the modified virus in the following way: A rabbit was inoculated with a portion of the tissue of the spinal cord of a rabid dog, and became affected in about fifteen days. When it was dead, a second rabbit was inoculated with a bit of its cord, and the procedure was followed through a series of sixty animals. With successive cultivations in the rabbits, the virus gets more and more intense, and finally the period of incubation in an animal inoculated is not more than seven days. By keeping portions of the spinal cords in perfectly dry tubes, the virus gradually diminishes in intensity; and the longer it is kept, the more attenuated does it become.

Having thus obtained a proper supply, a suitable subject was forthcoming in an Alsatian lad who, in the beginning of July, was severely bitten in many places by a dog which was undoubtedly rabid. Sixty hours after the bites the first vaccinations were made with very attenuated virus, and were repeated twice a day for a fortnight with virus of successively increasing strength, the last injection being from a rabbit which had died the day before, and in which the poison was intensely virulent. The previous inoculations with weakened virus had rendered him insusceptible to the strongest poison which would render rabid in a short time an unprotected dog or rabbit. One hundred days had elapsed since the last vaccination, and the young man remained well. A second case is undergoing similar treatment.

The strong point in this remarkable record is the fact that dogs subjected to similar inoculations are insusceptible, and do not take the disease even when injected with the strongest virus. The weak point is the short space of time which has intervened since the bites and since the last vacination with strong virus. It is well known that the period of inoculation of rabies may be many months, or even three or four years, though the average period is within one hundred days. Time alone will tell whether the two patients are actually protected. They have been doubly exposed to infection through the original bite and by the intense virus of the final vaccination; but we may reasonably hope that in them, as in the dogs, an immunity has been secured.

The nature of the virus has not yet been determined, but Pasteur supposes it to be a microbe, and the nervous system appears to be the chief seat of its development.

THE MIDWIFE IN PLATO.

IT has been suggested that the Egyptian Isis, the Greek Diana, or Artemis, and the Roman Lucina were simply celebrated midwives, who were given celestial honors because of their kind and successful

Digitized by Google

care of women in childbirth. Is reverence gone from among men that any should thus ruthlessly destroy myths once consecrated by common belief? Then, too, what sacrifice of poetic beauty is made when these fables are cast in the dust! Think, for example, of the beautiful Diana, the chaste virgin, who transformed Daphne into a laurel to save her from cruel pursuit, who caused Actæon to be devoured by his own dogs because he had seen her bathing, the beneficent being who clothed the meadows with verdure and flowers, and made the fields laugh with bounteous harvests, and who was honored with festal song and solemn sacrifice, especially by virgins and children, having once been, as was Phanærete, the mother of Socrates, "a big, burly midwife!" Nevertheless, many an old faith is cast aside with the progress of the race as a useless encumbrance, a sort of *impedimentum* as the Romans would call it, or as a garment that the wearer has outgrown. Time is as merciless to myths as avarice was to mummies. Of the latter, Sir Thomas Browne thus spoke more than two centuries ago: "The Egyptian mummies, which Cambyses or time hath spared, avarice now consumeth. Mummy is become merchandise, Mizraim cures wounds, and Pharaoh is sold for balsams."

But if the goddesses whom a past age adored are to be dragged from their thrones, and proved to be of common clay, at least there will always remain the opportunity of studying the characteristics of the midwives of old times from whose ranks these divinities, as it is alleged, came.

Probably we have in the Theætetus of Plato one of the best of ancient descriptions of the qualifications and duties of the midwife, and possibly a brief reference to that description may not be uninteresting. "No woman," says Socrates, he being represented as one of the speakers in the dialogue, "as you are probably aware, who is still able to conceive and bear, attends other women, but only those who are past bearing." The reason given for this restriction is, that "human nature cannot know the mystery of an art without experience." This rule, it is quite plain, not only excludes the young, but also the sterile. Similarly, Dionis, writing in the early part of the last century, states that the sage-femme must be married, saying that it would be bad for an unmarried woman to undertake an accouchement when "she was ignorant of all the circumstances necessary *pour faire un enfant.*" Obviously, too, the rule forever excludes male practitioners of midwifery, until the wishes that are occasionally expressed in the lying-in room, often jocularly, sometimes half seriously, to the effect that childbearing should be equally divided between the sexes, are realized.

Readers of George Eliot will remember that she has one of her characters assert that childbearing is done by women in "a poor, miserable, makeshift sort of a way," and that it would have been better if they had left it to the men. But to this judgment of a mysogenist Scotch bachelor, few men would joyfully respond amen.

Socrates next refers to the diagnosis of pregnancy, stating that midwives know better than others who are pregnant. Then their power, by means of potions and incantations, to rouse the pangs of labor and to soothe them at will, is referred to.

Socrates says that "midwives know best what unions are likely to produce a brave brood; if you reflect, you will see that the same art which cultivates and gathers in the fruits of the earth, will be most likely to know in what soils the several plants or seeds should be deposited." He further states that the "true midwife is, also, the true and only matchmaker." It seems that the familiar observation, probably made oftener at the beginning than at the close of married life, matches are made in heaven, is an error, or, as Byron would say, it is truth in masquerade, and that the potent agents in this work are midwives. We sometimes fear that the work of midwives in this regard is often badly done, or else domestic discord would be less frequent, and divorce courts have more rest.

The most important of the qualifications which Plato believed the midwife should have was experience. The same rule is urged in his "Republic" as to physicians: "Now skilful physicians are those who, from their youth upwards, have combined with the knowledge of their art the greatest experience of disease; they had better not be robust in health, and should have had all manner of diseases in their own person." Be merciful, O wisest of all Greeks! Life is too short for any one mortal to endure the hundreds of diseases to which flesh is heir. Life is too weak to bear such a burden. Let midwives continue to make matches, though the conflagrations that some of the latter kindle are most serious, but do not demand of the physician that he should have had all manner of diseases before he attempts to heal the maladies of others.

JAPANESE RAGS IN THE CITY OF PHILADELPHIA.

ON or about the 14th of October last, a cargo of Japanese rags, on board the ship "Lucy A. Nickles," was refused admission to the port of New York by the Health Officer, unless the rags were disinfected by a process approved by him. The consignees claimed that this processs is expensive, as well as destructive to the rags, and they refused to comply with the conditions.

The process referred to consists in submitting the

Digitized by Google

bales to disinfection by superheated steam applied by means of hollow screws or augurs (perforated with numerous holes) penetrating the bales, through which the steam is forced, and escapes only after permeating every part of the bale. The charges are said to be about five dollars per bale.

As entry was refused at New York, the rags (some 4910 bales) were transferred to schooners, and a portion brought to the port of Philadelphia, where entrance was sought, and the remainder is to follow in a few days. Timely notification of the above facts was given to the Board of Health of Philadelphia, before the arrival of the first schooner-load, and the matter was brought up for consideration at its meeting on the 27th of October. After a prolonged discussion, the whole subject was referred to the Lazaretto Committee, to report at the next meeting. On the following Tuesday, November 3d, the Committee, or a majority of it, reported against admitting the rags unless first disinfected. This report the Board sustained, after due deliberation and much discussion; but two days later, a special meeting of the Board was called, and a resolution was then adopted, by a vote of eight to three, allowing the rags to be landed and stored within the city limits, and without previous disinfection of any kind. In lieu of disinfection a bond was required of the consignees, in the sum of $5000, not to remove the rags from the warehouse without previous notification to the Board, and within the next ten days it is expected that the remainder of the cargo will be landed in this city.

Now, these rags purport to have come from Hiogo, Japan, but in what province of Japan they were gathered, and when, is an open question; and it is well known that cholera has existed in Japan for the past twelve months, and that smallpox is always there —indeed, during the first six months of the present year nearly 5000 cases and over 1000 deaths have been reported. With the knowledge of these facts before them, as well as the sad experience of a few years ago in this city, to say nothing of the knowledge of the results of the fearful scourge now prostrating Montreal, it is criminally imprudent to admit into the country foreign rags from an infected locality without previous disinfection. It is, moreover, a very dangerous precedent, and at once invites rag merchants everywhere to a haven they have long sought.

If rags from one country well known to be infected with two of the most dangerous diseases that assume an epidemic form, can obtain admission to Philadelphia without undergoing disinfection, there is no reason why they should not be admitted from any country, regardless of its sanitary condition. We wish here to enter our most emphatic protest against this utter disregard of the dictates of common prudence and this rash endangerment of the lives of our citizens.

DEATH OF DR. WILLIAM B. CARPENTER.

NOWHERE is it so dangerous as in England for a medical man to acquire a reputation in any department of literature or science that does not bear directly upon tongues and pulses, and yet in no country has the medical profession so many scientific workers of the first rank. From the time of John Hunter, the reputation of the British school of biologists and comparative anatomists has rested largely upon the labors of physicians and surgeons in these departments, and a glance through the files of proceedings of the scientific societies will show what a prominent part they continue to take in the work. The members of the profession who have influenced their generation most widely in this direction in England are Professor Owen, Professor Huxley, and Dr. Carpenter. All three began life as practitioners, but soon relinquished the cares of practice for more congenial pursuits, retaining at the same time very close connections with the profession—Owen as Conservator of the Hunterian Museum, Carpenter as author of the largest and, for years, the best text-book on physiology, and Huxley as author of several works extensively used by medical students.

Dr. Carpenter was very widely known in this country through his *Human Physiology*, which was a favorite text-book for many years, and passed through eight editions. His works on *Comparative Physiology*, and on the *Microscope*, were also republished, and had large sales. As the successor of Forbes in the editorship of the *British and Foreign Medico-Chirurgical Review*, and as Professor of Medical Jurisprudence at University College, he retained very intimate relations with the profession for many years after his removal from Bristol to London, in 1844.

Dr. Carpenter's reputation as a physiologist rested chiefly on his text-books, and he had experienced in this department a foretaste of that oblivion which certainly awaits the author of such works. He will be long remembered by his later investigations upon human automatism, and the work on *Mental Physiology* will outlive many of his other better known books. But his permanent scientific position depends upon the careful researches which he made upon the Foraminifera and other low forms of life, and his investigations in connection with the deep sea dredging expeditions. Throughout a long professional career of fifty years, he was always to be found on the side of progress and humanity, and the profession and the race have been made better by his life.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 5, 1885.

THE PRESIDENT, A. JACOBI, M.D., IN THE CHAIR.

REPORT OF THE SECTION IN OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN.

DR. A. S. HUNTER, Chairman, reported that at the last stated meeting of the Section, held October 22, Dr. Howard Pinckney presented a *Hydrocephalic Head of a Colt*, the face of which bore a remarkable resemblance to that of a bull-dog. On account of the large head the dam died in labor; though Dr. Pinckney thought her life might have been saved if craniotomy had been performed. During her pregnancy a large bull-dog was in the stable where the mare was kept.

Dr. Malcolm McLean afterwards read a paper on the *Management of Unfavorable Cephalic Presentations at the Superior Strait*, especially the occipito-posterior positions. In posterior positions of the vertex, when the head cannot be satisfactorily rotated anteriorly by the hand of the accoucheur, or where it will not remain in the anterior position, he advocated podalic version, accomplished by the combined method, in preference to the use of the forceps, the method usually adopted.

DR. D. B. ST. JOHN ROOSA read a

SKETCH OF THE LIFE OF JAMES LAWRENCE LITTLE, M.D., AND OF THE TWENTY-FIVE YEARS IN WHICH HE PRACTISED SURGERY IN NEW YORK.

In April, 1860, Dr. Little began his duties at the New York Hospital as a junior walker, and in April, 1885, he died; so that it may be truly said that a quarter of a century bounded his professional career. In the hospital, Dr. Roosa said, he gave promise of his future career. He was assiduous and faithful as an assistant, and suggestive and enthusiastic as a house surgeon. It was while in the hospital that he devised his method of making and applying plaster-of-Paris splints, and he thought it is not too much to say that chiefly, if not entirely, through Little's efforts plaster-of-Paris splints became a practical application. His best qualities as a surgeon, a teacher, and an executive officer, were seen after his appointment to the Chair of Surgery in the University of Vermont, in 1875. In Burlington, as in New York, "Little's bench" became proverbial, for his operations were preëminently successful.

In reference to his surgical ability, Dr. Roosa said: "Of Dr. Little's surgical achievements in detail, I am not competent to speak, nor is it necessary that I should do so. They are indelibly recorded in surgical literature—at least in part, for of late years Dr. Little was somewhat regardless, from lack of time, perhaps, from his large and exacting public and private practice, to write as much as his friends might have wished. But I may say that he was the first American surgeon to puncture the bladder with the aspirator for the relief of retention of urine. He simultaneously ligated the subclavian and carotid arteries of the right side for aneurism of the first part of the subclavian. The operation for stone by various methods he had performed seventy-seven times, with a fatal result in but two cases; in hare-lip and strangulated hernia he also had a large and successful experience."

DR. PAUL F. MUNDÉ read a paper on

ELECTRICITY AS A THERAPEUTIC AGENT IN GYNECOLOGY.

Before commencing it he announced that, in consequence of the shortness of the time at his disposal, he would necessarily be obliged to omit certain portions of it. After a brief reference to the literature of the subject, he spoke of the obstacles which stand in the way of the adoption of electricity in general obstetric practice, and went on to say that these do not apply to that of gynecology, in which the patient is usually seen by the physician at his office, where she can be treated deliberately, and where the necessary appliances can always be kept ready for use. No special precautions are required in the application of this agent, and, indeed, the patient is often entirely relieved by it of the pain from which she was suffering when she came to the consulting-room.

The range of its applicability is quite large. The faradic current is especially indicated in malnutrition of the sexual organs, amenorrhœa, irregular menstruation, subinvolution, etc., and the galvanic in such troubles as pelvic neuralgia, fibroids, hyperplasia uteri, etc. The use of the galvanocautery was not considered within the scope of the paper, as in this the heat produced is the essential therapeutic factor. The routine use of electricity, he said, is certainly very uncommon in gynecological practice, and yet he himself, although by no means an expert in the use of this agent, had obtained some very excellent results with it during the last ten or twelve years, employing it in various affections with more or less benefit.

There are certain cardinal points to be remembered, enumeration of which is necessary before proceeding to speak in detail of his experience in special forms of disease.

First. The galvanic current is far more generally useful than the faradic, which, as a rule, has a stimulating effect. The galvanic, on the other hand, acts as a sedative.

Second. A mild, steady galvanic current will answer every purpose, and is in every way preferable to a powerful, interrupted one. The faradic current, however, is useful in proportion to its strength.

Third. Whenever the constant current causes pain, it is doing harm.

Fourth. Personally, he could never decide which pole, the negative or the positive, should preferably be placed within the body, provided care was taken that the current should not be too strong. The effect is apparently the same, whichever pole is used internally. There is, however, one prominent exception. In cases where there is circumscribed pain, the positive pole is the one to be placed near the painful point. In using the faradic current, it is of no consequence which pole is employed internally or externally.

These remarks, Dr. Mundé said, he wished to be distinctly understood as applying exclusively to the use of electricity in connection with the pelvic organs, and not to its effects in other portions of the body, such as the principal nervous centres, for instance.

Digitized by Google

Fifth. He had always found it safe to begin with a mild current and gradually increase it to the required strength.

Sixth. When internal electrolization is to be employed, it is always best to introduce the internal pole before closing the connection, on account of the sensitiveness of the external parts. Dr. Mundé said he employed an electrode covered with leather for introduction into the vagina, but that he had been recently informed by an electrologist that this in reality afforded no protection to the parts.

Seventh. To be of any service, the treatment must be frequently repeated, and must be continued for a considerable length of time. As a rule, it is useless to make applications less frequently than twice a week, and in many cases they should be made every other day. A course of treatment by localized galvanization should last from three to six months.

Eighth. The results of faradization in chronic affections are less favorable than those of galvanism. But, while relief from pain and an amelioration of the general condition are very often obtained by this means, a complete cure is not to be looked for in many of the affections which come under the gynecologist's notice.

Among the pathological conditions referred to in which treatment by electricity is applicable, were the following:

Deficient Development of the Uterus and Ovaries. If the organs are merely rudimentary, nothing is to be hoped from this or any other treatment; but if the uterus is of the normal shape, though small (such as is seen in the *uterus infantilis*), and there is any tendency whatever to a molimen shown, there is a fair prospect of good results. Here the faradic current is to be employed, aided by the use of sponge-tents and appropriate constitutional measures. Such amenorrhœa is often associated with stunted growth, mental hebetude, etc., and the faradization should be applied every other day for a series of months. For a week before the time of the expected period, the current should be employed with increased strength and for a long time at each sitting. When the molimen is entirely absent, little is to be hoped for. Dr. Mundé did not think a galvanic stem allowed to remain in the uterus is of any special value, believing that whatever benefit is derived from such a contrivance is due simply to the fact that it is a foreign body, and thus has more or less irritative effect upon the uterus.

Chlorosis and amenorrhœa (including deferred and irregular menstruation) are often relieved by electricity, but it is by no means proper that very young girls suffering from such troubles should be subjected to a course of treatment by this agent. The cases are to be carefully selected, and the application of electricity is to be combined with judicious constitutional measures, as well as other local treatment. Perseverance is also essential to secure any good result.

Of course, the possibility of a physiological cause for the absence of the menses is not to be overlooked. In married women electricity will be called for in the treatment of amenorrhœa much more frequently than in unmarried, and it is often of great service when the circulation is sluggish and the energies of the system are directed rather to the formation of adipose tissue than towards the pelvic organs. The same is true as regards some unmarried women, and it is not infrequently found that when the flesh has been reduced the amenorrhœa disappears. No reliance, Dr. Mundé thought, is to be placed on the emmenagogues of the books. Better results are to be obtained, however, with permanganate of potassium; though no other agent is to be compared with electricity in value.

Subinvolution and Menorrhagia. Here the faradic current is indicated, at least in recent cases. In others of longer standing the constant current is of most service; though the electrode is not to be introduced within the uterus. In hyperplasia uteri galvanization is often of very great benefit, both for the relief of reflex neurosis which it affords and its utility in the removal by absorption of abnormal tissue. In this condition the long and frequent application of the current is called for, and intrauterine medication is to be employed in addition. In the rare condition of superinvolution Dr. Mundé had had no experience, but he said he would advise the same treatment for it as for amenorrhœa.

Chronic Oöphoritis and Pachysalpingitis. These affections are extremely painful and annoying, and he thought that the condition of the ovaries is quite analogous to that of the tonsils after repeated tonsillitis. The successive attacks result in a permanent increase of hyperplastic tissue. In enlarged tonsils there is no cure except removal, and a cure is not to be expected in the ovaries. The same is true in regard to chronic catarrh of the Fallopian tubes, and on account of the hyperplasia of the walls of the latter, he had ventured to apply the term pachysalpingitis. In connection with this trouble there is also peri-oöphoritis, or localized perineal inflammation, and the sufferings incident to the whole condition usually rendered life a burden. The only cure is salpingo-oöphorectomy, and in Lawson Tait's hands it has proved an operation comparatively free from risk, but it must be remembered that no other operator has met with the same extraordinary success. In addition to the danger under ordinary circumstances, there is a grave objection to subjecting young married women to an operation which deprives them of all hope of offspring, especially as a number of instances are on record in which conception and pregnancy have occurred in women in this condition. It is better, therefore, to reserve operative interference as a last resort, only to be undertaken in cases of extreme suffering when every other means of relief has failed, except in those instances where imminent danger to the patient calls for the prompt performance of the operation. Dr Mundé said that he had seen very great benefit derived from palliative treatment, and the use of electricity is often of great service in supplementing other local measures. It relieves pain for hours or even days at a time, and by its anæsthetic influence renders the diffuse thickening in the broad ligament less tender to the touch. While it is true that the relief is only temporary, there is in many cases a chance that pregnancy may occur, and in others that the menopause will soon supervene. The radical operation should be deferred, then, until it is absolutely called for.

Chronic Pelvic Cellulitis, Peritonitis, and Lymphangitis. The ordinary treatment for old pelvic adhesions affords very little relief, and there is nothing by any means equal to a mild constant current for this purpose. Acute or subacute exudations, however, do not offer a proper

Digitized by Google

field for the use of electricity, on account of the danger of setting up new trouble. In lymphangitis the mobility of the affected glands, as a rule, distinguishes the affection from pelvic peritonitis, in which the masses of hard hyperplastic tissue are immovably fixed. The glands often feel like a bundle of angle-worms under the fingers. Their inflammation is usually secondary to some process of irritation, such as a lacerated cervix, etc., and for the chronic condition localized galvanization constitutes the most efficient treatment.

Obstructive and Neuralgic Dysmenorrhœa. The obstruction at the os uteri may be very slight at ordinary times; but when the endometrium becomes congested at the menstrual period, it is sufficient to give rise to much suffering by impeding the free exit of the flow. When other means have failed to relieve the difficulty, galvanic electricity will often be found of very great service; the negative pole of the battery being carried up into the uterus, and not more than ten cells being used. In some cases the pain was relieved very quickly by this means.

Uterine Displacements, Fibroid Tumors, etc. Electricity had been applied to relaxed ligaments in malpositions of the uterus, and good results reported; but he said he had had no experience with this method of treatment. In uterine fibroids he thought it had a future. Apostoli, of Paris, had reported quite remarkable results at the International Medical Congress at Copenhagen, and Everett, of Ohio, had also met with success in this field. The methods at present in use are, at all events, safe; which is more than can be said of the electro-puncture of Kimball and Cutter, which in more than one instance has resulted fatally. Dr. Mundé then referred to a case which he had seen in consultation with Dr. Freeman, of Brooklyn, who afterwards produced a cure by electrolysis, and reported it in a paper read before the King's County Medical Society. It was one of subperitoneal fibroid, and the galvanic current was applied by means of a sharp steel needle insulated to within a short distance of its extremity, thrust into the tumor. He thought that perhaps the necessity for putting the patient frequently under the influence of an anæsthetic may prove an objection to the method.

Conclusions. At the close of the paper the following conclusions were given:

First. Electricity is a valuable agent in gynecology, and one which deserves to be much more frequently resorted to than is now the case.

Second. Its application in gynecological practice does not require a special knowledge of the use of electricity.

Third. The remedy, if properly used, cannot do harm.

Fourth. It is of especial service in chronic conditions, and no pain is experienced if the galvanic current is employed.

Fifth. The faradic current is indicated in deficient development and want of tone in the pelvic organs.

Sixth. The galvanic current is to be used to promote absorption of adventitious products and allay pain.

Seventh. This method of treatment requires much perseverance.

Eighth. It is contraindicated in acute inflammatory conditions.

Ninth. The pathological conditions in which electricity proves useful are those in which other treatment often fails, or cannot be borne by the patient.

Tenth. In organic diseases a permanent cure or a restoration of the diseased organs to perfect health cannot be expected; but very marked relief, and that without danger, may often be afforded by means of electricity.

DR. FREEMAN, of Brooklyn, said that he coincided with Dr. Mundé in almost all that he had said. He commenced to use electricity in his practice some twenty-five years ago, when he was living in Illinois. At that time he employed only the faradic current. Sixteen years ago he removed to Brooklyn, and just afterwards a dyspepsia from which he had long been suffering culminated in acute gastralgia. For this he tried the faradic current, but without relief; and he was afterwards cured of it by means of the galvanic. He has now almost entirely given up the use of the faradic current except for the purpose of exciting muscular contraction, and this can also be accomplished by means of the interrupted galvanic. There is one other form of electricity which is not mentioned in the paper, viz., the static, and during the last four years he has used this forty times as often as either of the others in his practice. It has a great advantage in that it can be employed so easily and so pleasantly to the patient, and the removal of the clothing is not required as when they are used. One of the most useful purposes which electricity secures is the relief of pain, and on this account it has proved a great blessing, as it enables us to a large extent to avoid the use of opiates. Under the application of the static current pain often disappears like magic, and the patient feels a pleasant exhilarating effect not unlike that from champagne, but without any attendant disagreeable results.

Dr. Freeman then went on to speak of the treatment of uterine fibroids by electricity, and stated that he had that day seen the patient to whom Dr. Mundé referred in his paper. All that is now left of the tumor is some thickening of the uterine walls at the point where it had been situated. In this case the uterus was firmly bound down by adhesions, and the use of the knife was out of the question. He then mentioned the case of another patient, a married lady 26 years of age, who had a uterine fibroid. The tumor was as large as a cocoanut, and the cavity of the uterus measured four and three-quarters inches in length. The bladder was attached to the whole anterior surface of the growth, and severe cystitis had been set up by it. Posteriorly, it pressed upon the rectum, and caused great difficulty with the bowels. The patient also suffered greatly from dyspepsia, and was constantly confined to bed. On the 28th of February last she was put under an anæsthetic and electrolysis was resorted to; a round insulated steel needle being used for the purpose. On account of the density of the tumor the needle was introduced with great difficulty, and it was almost impossible to move it from one point to another. Thirty-two cells of a zinc-carbon battery were used. Afterwards the galvanic current was employed for two months for the relief of the dyspepsia and the patient's general condition. The tumor was then little more than half its former size. At the second operation, at which Dr, James B. Hunter, of New York, was present, the needle entered without any difficulty, and could readily be moved about in any

Digitized by Google

direction, so greatly softened had the dense tissue become. In June the operation was again repeated, the patient in the meanwhile having been up and attending to her household duties all the time. In August she walked three-quarters of a mile to his office, and was found to be in excellent health. At present there is only some thickening of the anterior wall of the uterus left, and the organ is about the normal size.

A third patient, who lives at Saratoga, he saw for the first time last spring. He found there were two tumors in this case, and he gave her three treatments; eight days elapsing between the first and second, and one month between the second and third. A fourth treatment was given at her own home, in Saratoga, in the summer, and at this time he found that the larger tumor had disappeared altogether, while the smaller one was reduced to about one-half its former size. Since then the latter has disappeared also; but when he saw her last week, he discovered still another tumor, which appeared to be of a floating character and entirely separate from the uterus. This was treated November 2d, in the same way; on this occasion a Barrett chloride of zinc battery of fifty cells being employed, and the electrolysis kept up for fifty minutes. In none of these cases had there been any rise of temperature after the application of electricity in the manner described.

DR. A. D. ROCKWELL said that he had held for a long time that electricity should hold a higher position in gynecology, as well as in general practice, than it hitherto has done; and he was, therefore, much pleased to hear an expert gynecologist, like Dr. Mundé, making a plea for its more general employment in this department of medicine. While not, of course, a panacea, it is a remedy which has a very wide range of usefulness. He had seen it employed in the various conditions to which the author of the paper had referred, and could testify to the correctness of his statements. In subinvolution, however, he would expect that the galvanic current would be of more service than the faradic. The thing that interested him most, he said, because it was a new application of the remedy, was the use of galvanism in pelvic cellulitis. Electricity may now be well considered indispensable to the gynecologist.

DR. H. J. GARRIGUES said that for about thirteen years he had used this agent more or less in gynecological practice. The chief reason why he had not used it more is because it takes too much time. Dr. Mundé had stated in his paper that it is sometimes necessary to devote half an hour every other day to the treatment, and he did not see how any one actively engaged in practice could spare so much time as this. Another reason is, that he has found that he can get as good results with other remedies which do not occupy so much time. The condition in which he has most frequently employed electricity is amenorrhœa, and in this it has not always answered the desired purpose, not only in cases where the uterus, but also in those in which the difficulty was merely functional. The simple introduction of the sound, by its mechanical irritation, had proved about as useful as any other method of treatment in amenorrhœa. Internal remedies, especially iron and permanganate of potassium, had also proved quite satisfactory in his hands. As to the treatment of fibroids by electricity, the reports of so many favorable cases certainly deserve to call the careful attention of the profession to the subject. He would merely say, in conclusion, that one difficulty which he had met with in the use of galvanism was, that even with a weak current, the electrode introduced within the vagina produced an escharotic effect.

DR. BIRDSALL thought that the author of the paper had, on the whole, expressed sound views. The literature of the subject, it must be confessed, is rather mystifying and unsatisfactory. One great difficulty is to find out what the observers who have reported cases have really used. He believed, however, that the time is coming when by the more general spread of knowledge on this subject we shall have a better opportunity to compare notes. Dr. Mundé had stated that it is not necessary to have great skill in the use of electricity to apply it successfully in gynecological practice. While, however, good results may be obtained without this, he thought that much better results can be secured by the employment of more exact methods, and that the adoption of the latter will also have a better effect upon the profession from a scientific point of view. At present, one of the great difficulties met with is to get at the strength of the current applied in any given instance. The number of cells reported as used, while (provided the battery is in good working order) it may act as a guide to those who are familiar with exactly the same apparatus, conveys no idea of the power employed to others reading the account. The only real test is the galvanometer, and, notwithstanding the difficulties in the way of using it, he trusts that it will be generally adopted at no distant date. As to the matter of subinvolution, he thought that galvanism is much more serviceable than the faradic current, which is indicated in all cases where we wish to excite muscular contraction or cutaneous irritation. The most important, perhaps, of the conclusions enumerated by the author of the paper, is the one in which the caution is given about using electricity in acute and subacute cases. The effects of this agent, he went on to say, are exceedingly transient, and the applications should, therefore, be often repeated; as, for instance, every other day. When this is done, a very mild current will answer every purpose.

DR. MALCOLM MCLEAN remarked that Tait's operation is being overdone. Though he has performed it himself but once (and, fortunately, with a good result), he has seen a great many cases of it, and there is one point about the operation which does not appear in the reports of it. This is, that the effects are not usually so lasting as generally supposed, and he thought that if all the cases which are reported as cured were to be examined at the end of say eighteen months, fifty per cent. of these patients will be found to be suffering with the old pelvic pain. Hence, the results are by no means satisfactory, and he believes that in the future galvanism will to a large extent take the place of Tait's operation.

DR. BURKE mentioned three cases of metrorrhagia and menorrhagia in which trachelorrhaphy was performed with no effect, but in which positive results were obtained from the use of the faradic current. When it was commenced, galvanism had already been tried in vain; yet in from two to four months the patients were all cured by faradization. Nearly two years have now elapsed, and the results have been permanent.

Digitized by Google

DR. MUNDÉ, in closing the discussion, said that most of the points referred to by Dr. Birdsall were touched upon in the portions of the paper which it was necessary to omit in the reading. This was also true of the objection which Dr. Garrigues had raised, as to the amount of time required, since he had distinctly stated then that the process is a very tedious one, and that it requires no little personal sacrifice on the part of the gynecologist to carry out; but, nevertheless, if the patient's interests demand it, and the same results cannot be obtained in any other way, he thought it the physician's duty to perform the task. In regard to subinvolution, he recommends the faradic current only in the early stages with menorrhagia. Afterwards the condition is very much the same as in hyperplasia, and the galvanic current is chiefly to be used. He has never had any experience with static electricity, and should be glad to give it a trial. He did not wish to be understood to mean that no skill is desirable in the application of electricity in gynecology; but only that intelligent physicians, not specially skilled in it, can do great good with it, though he quite agrees with Dr. Birdsall, that a high degree of skill is very desirable in order to secure the best results possible. His object in the paper had been to popularize this method of treatment in gynecology, so far as he is able to do so.

THE PRESIDENT said he was very glad that the paper had been read, as he thought it was very much needed. Within a day or two he had taken the trouble to rush through three of the most important works on gynecology by German authors, and the use of electricity is scarcely alluded to in them. The same is true of gynecological literature in general, and about all the knowledge at command on this subject is to be found in works devoted to electro-therapeutics and neurology. Having expressed his surprise that the author of the paper had not referred to the brilliant results obtained by Thomas, by the use of electricity in extrauterine pregnancy, Dr. Mundé stated that in the part of the paper which has been omitted he had spoken of the matter, though as it is one pertaining rather to obstetrics than to gynecology proper, he had not given it a detailed notice.

PHILADELPHIA PATHOLOGICAL SOCIETY.

Stated Meeting, October 14, 1885.

THE PRESIDENT, J. C. WILSON, M. D., IN THE CHAIR.

DR. J. COLLINS WARREN, of Boston, read a paper on

A COMPARISON OF THE CHANGES IN ARTERIES AFTER LIGATURE AND IN THE DUCTUS ARTERIOSUS AND UMBILICAL ARTERIES AFTER BIRTH.

After the ligature of an artery in continuity, the earliest changes noted are the formation of the thrombi within the vessel, and the development of a mass of inflammatory tissue or callus around the point of ligature externally. No perceptible cell action can be observed in the inner wall, with low powers, during the first week, although under favorable circumstances a proliferation to a limited extent of the endothelial cells near the point of ligature can be seen with high powers, and occasionally a few wandering cells may be found to have penetrated the walls of the vessel at the same point. In the second week the bundle of fibres of the adventitia, which were surrounded and held by the knot, have been absorbed, and the two ends of the vessel retract slightly from one another, leaving the ligature embedded in and partly disintegrated by the granulation cells. The walls of each portion appear to form a complete cul-de-sac, and it looks at this time as if the healing process were complete; but it can hardly be said to have more than begun, as the vessel has not yet passed through what may be considered as the first stage of healing.

The beginning of the second stage is marked by an unfolding of the ends of the vessel, the walls separating somewhat after the manner of opening of a bud, which permits the entrance of a considerable quantity of the granulation tissue. A disintegration of the thrombus follows and we have now a fully developed external and internal callus, a small fragment of clot still protecting the latter from the current. The ligature may be totally disintegrated and absorbed, or it may have become encysted, or finally it may have created a small abscess about itself which has discharged the fragments of thread through a sinus opening externally.

The second stage is completed when the internal growth has reached the neighborhood of a branch. After this we have an absorption of the callus, which, as in fracture, is only a provisional structure, and eventually the two ends of the vessel are found held together by a slender cord of varying length. The walls of the vessel are slightly separated at each end by a cicatrix consisting of connective tissue externally, inside of which is another layer consisting largely of unstriped muscular fibre, the surface being covered within by a new endothelium. The cicatrix is always pierced by a vessel which terminates in a number of capillaries ramifying in the cord. We have here a scar made up of three layers resembling closely the three coats of the vessel. In the large vessel of amputation stumps we have a somewhat different series of changes. Soon after the ligation the end of the vessel may be seen embedded in granulation tissue and containing a thrombus of varying length. By the second week there is a marked change in the intima extending for some distance above the point of ligation, probably to the first large branch or to the origin of the vessel. Examined several months later, when the healing process has been completed, the vessel is found to be preserved in the form of a cord running from the first large sized branch to the cicatrix of the stump; on laying open this cord the walls of the vessel are found preserved, the interior being filled with new tissue leaving spaces occupied by one or more vessels. There has been a process resembling that known as obliterating endocarditis, by which the calibre of the blood channel has been narrowed to an extent to adapt it to the diminished blood-supply. In this obliterating tissue we find comparatively large vessels with new coats consisting of an endothelium, an elastic membrane, and also a new media. An erosion preparation would best represent the condition of the arteries of the stump at this time. The main artery would, after giving off its largest branches, break into a spray of smaller vessels no one of which would predominate.

A comparison of these two modes of healing with the changes seen in the arterial system, seen after birth, shows certain resemblances in the two processes. The ductus arteriosus about the time of birth differs consider-

Digitized by Google

ably from the structure of the aorta and pulmonary artery. The media is much thicker than in either of these vessels, it is thrown into irregular folds which are increased at the time of birth, and help to narrow its calibre. The distinctions between the different layers of its wall are less marked than in other vessels. The lamina elastica is indistinct, and in places apparently wanting; the media consists chiefly of longitudinal layers of muscular fibres, a few circular bundles existing in the innermost layer. A few weeks after birth a greater portion of the walls of the ductus undergoes hyaline degeneration, the inner or circular fibres of the media alone remaining, these being reinforced apparently by a growth from the media of the larger vessels. At this time there is an active growth of long spindle-shaped cells with staff-shaped nuclei at the edges of the media bordering on the opening into the aorta, there is also a moderate thickening of the intima. Eventually the hyaline tissue becomes absorbed and is replaced by a ligamentous band of fibres which becomes continuous at either end with the media of the larger vessels. At the aortic end in a longitudinal section we see the media slightly separated. At the point of the cicatrix, and between them, and also continuous with them, are the longitudinal fibres of the ligamentum arteriosum. In this ligamentous tissue, and between the edges of the media, are numerous new muscular cells; nearer the surface is a layer of thickened intima, which in the aorta has not only connective tissue in it, but also a deep musculo-elastic layer; in the centre of the depression marking the site of the cicatrix, a small vessel is given off which penetrates into the axis of the ligament, where it either loses itself in a capillary network or becomes continuous with a similar vessel coming from the pulmonary artery. We have here conditions closely resembling those which have been described as existing in the cicatrix of a large artery after ligature in continuity, namely, the slightly separated ends of the media between which lie the fibres of the ligament connecting it with the pulmonary artery, a new intima, and a new growth of muscular cells, and finally a central arteriole. The only point of difference is the preservation of a layer of muscular fibres which form an outer wall to the ligamentous band, a much-needed support at a point exposed to great tension. Further protection is afforded by the oblique insertion of the ductus into the aorta, diminishing the pressure upon this particular point.

At birth the umbilical artery, or that usually called the hypogastric artery, the portion within the abdomen, at its origin from the internal iliac, is a vessel of considerable size; being, in fact, a continuation of that artery. At its termination in the umbilical wound it has greatly contracted, and is filled with clot for a distance of about one inch. The outlines of the various walls are not as distinct as in other vessels, and the elastic lamina are for the most part wanting. No special change is seen in the elements of the walls of the vessel, except a slight accumulation of endothelial cells near the apex of the thrombus. A few weeks later there is a distinct growth on the inner surface of the wall up to its point of origin, the terminal portion having undergone a hyaline degeneration and obliteration for a short distance. The vessel has greatly contracted throughout its entire length, and its calibre is further diminished by the growth in its interior. Cross sections taken from the superior vesical artery in adult life show the media as a wall, thick out of all proportion to the size of the vessel, and consisting not only of its original wall, containing longitudinal muscular cells interspersed with elastic tissue, but also an inner circular row of cells, which is provided with a well-formed elastic lamina. It seems probable that the greater portion of the hypogastric artery has been preserved, the ligamentous band, which extends to the umbilicus consisting of the obliterated extremity of that vessel much elongated during the process of growth. The series of changes which occur in the hypogastric artery after birth is closely analogous to that seen in the main trunk of an amputation stump—a slight portion of each vessel is destroyed, both retract and are attached to the terminal cicatrix by a band of fibrous tissue, both remain as previous vessels with thickened coats and narrowed calibre. In both the process is not unlike that seen in the so-called obliterating or compensatory arteritis. Arteritis hardly seems a term applicable to the changes taking place in normal arteries after birth, nor can the alterations which have been developed through the whole length of a large vessel, extending a considerable distance from the original seat of inflammation be strictly regarded as of an inflammatory nature. May not the obliterating growths found to exist simultaneously in terminal arteries in widely removed portions of the body of the same individual also be regarded, not as of inflammatory nature, but rather as a secondary and formative process, closely connected with disturbances in the mechanism of nutrition, designed to adapt the vessels to a diminished blood-supply?

DR. S. W. GROSS said, in view of the fact that Dr. Warren's teaching seemed so directly opposed to that of other observers, he would like to have some points cleared up. He would, therefore, ask whether Dr. Warren held: 1st, that instead of the external coat's sloughing and coming away with the ligature, where it is so included, the pressure of the ligature sets up an irritation which causes the adventitia to return to its embryonic state with a reconversion, after the ligature has cut through this, to connective tissue; and, 2d, whether the repair of arteries is brought about by the ingrowth of the cicatricial tissue, which he likened to provisional callus. together with some proliferation of the muscular cells of the media.

DR. RANDALL said that, as the result of careful study of the subject, he had always found the clot present at first, and that it was honeycombed, even in the first few days, by the contraction of its fibrin, through the spaces thus formed the blood seemed to be circulating. Cells, either original white cells, or of endothelial origin, occupied the walls of these cavernous spaces, and seemed to sheathe them. The red cells early melted down into a homogeneous mass, furnishing the framework upon which the reparative tissue was built. The "plastic clot" of some observers he had not seen, the new cells being distributed throughout the old clot as well as upon the vessel walls, and not specially collected in the immediate neighborhood of the ligature. The obliteration of the vessel was accomplished by the growth and contraction of the trabeculæ of new tissue built upon the remains of the original blood clot. Even close to the ligature he had not found the vessel walls greatly altered, merely showing a great increase in the nuclei and in the number and size of the vasa vasorum, the

Digitized by Google

lamina elastica being distinct, and as a rule intact. Toward the end of the first month the new tissue was largely spindle-cells, but careful staining had given no suggestion of muscular tissue. But, not having carried his study beyond the first month, he had no data upon this subject, since the development of muscular tissue is claimed to occur only at a later stage.

DR. FORMAD was inclined to favor the views of Dr. Randall. The observation of Dr. Warren, that the new-formed connective tissue played the most important part, was to him entirely novel. He thought probably that pressure upon the artery from without, with consequent diminution in its lumen, might bring about a condition more analogous to the growth of fœtal life than to inflammation.

DR. MEARS remarked that we are liable to be confused in considering this subject by the presence of the blood in the vessel. So far as the process of healing after ligature is concerned, we may consider only the structures which enter into the formation of the vessel wall, which is complex in character and composed of connective, elastic, and endothelial tissues. Dr. Warren has given us a very clear demonstration of cicatrization as it occurs in these structures after application of the ligature.

DR. TYSON said the most novel feature to him in Dr. Warren's observations was the part played by the muscular tissue. This apparent increase in the muscular tissue he was inclined to believe is only a proliferation of intramuscular connective tissue. He is becoming more and more convinced that there is only one kind of inflammation, the interstitial. He feared that he might himself mistake a proliferating connective tissue with spindle cells for muscular tissue. It is true that new-formed capillaries and arterioles have muscular walls, but the development of these seemed to him to be a slower process. He had expected to find a process of repair in the ductus arteriosus different from that in an ordinary artery. This process, he had expected, would be a true endarteritis, for it seems that the conditions of closure here are rather different from those in the ligaturing of an ordinary artery, and in the umbilical artery where we have also ligation practised.

DR. WARREN, in closing the discussion, said that in cases where there is much breaking down and little repair, there might be a sloughing of the external coat, yet in his experiments this part of the arterial wall did not slough, but was simply absorbed by the granulation tissue, as is the ligature itself in some cases. In the normal condition even the elastic lamina is not a perfectly continuous plate; he did not refer to these breaks, however, but to numbers of little ruptures incident to the pulling out of the wound of an artery in the act of ligature—however, this need not necessarily occur. He had not attempted to identify anything like muscular tissue early; this could not be recognized till we had a permanent cicatrix formed. He had carefully eliminated all sources of error, and it seemed to him that in almost all cases there was a considerable number of these muscular cells. The layer was not always as well marked as in his diagrams, especially is this true of human cases, but these had all been in alcohol for some years; of the fresh specimens he had selected only those in which he had considered the process complete. In a specimen which he had here to-night, through an opening in the lamina elastica cells could be traced from the muscular layer, those in the inside resembling exactly those outside. These facts, together with the fact that we have normally a few muscular cells inside of the lamina elastica, lead him to believe in the proliferation of the muscular tissue. The disintegration of the blood-clot is accomplished by granulations growing inward from the callus, there being two sets of bloodvessels, one in the granulations, the other (blood-spaces rather) in the clot itself; these unite about the end of the first or second month.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, October 6, 1885.

THE PRESIDENT, W. R. BIRDSALL, M.D., IN THE CHAIR.

DR. E. C. SEGUIN read a paper entitled

A CONTRIBUTION TO THE PATHOLOGY OF HEMIANOPSIA OF CENTRAL ORIGIN; CASE WITH SPECIMEN.

He first gave a brief synopsis of views, anatomical or pathological, of hemianopsia of basal or peripheral origin, recognizing the following types:

1. Horizontal hemianopsia, superior or inferior, usually due to lesions within the eye, and hence of less interest to the neurologist.

2. Vertical hemianopsia, always caused by a lesion of the basal visual apparatus, or by disease in a certain limited part of the cerebrum.

a. Temporal hemianopsia, in which the temporal half of both visual fields is dark.

b. Nasal hemianopsia, in which the nasal half of both visual fields is obscured.

c. Lateral hemianopsia. This is often designated homonymous hemianopsia. In this variety the nasal half of one visual field and the temporal half of the other are dark, so that with one or both eyes open the patient sees the same half of any object placed in front of him. This variety is the one which results from a truly central lesion, and forms the object of study in the paper.

Varieties *a* and *b* are caused by lesions variously placed in or around the chiasms of the optic nerves.

The author proceeded to analyze the recorded observations of hemianopsia due to cerebral lesion, 42 in number, including the author's own case. Of these, 37 were medical, and accompanied by autopsies; 5 surgical, followed by survival of the patient. These relatively numerous observations were classified as follows:

a. Cases of lateral hemianopsia, indefinite or irrelevant, and useless for localization study, 34 in number, observed by Charcot and Pitres, Linnell, Wiethe, and Petrina.

b. Cases of lateral hemianopsia from lesions of parts of brain not directly related to the optic apparatus, 3 cases; by Hirschberg, Huguenin (Obs. of 1876), and Pflüger.

c. Cases of lateral heminanopsia from lesions involving chiefly the thalamus opticus or corpus geniculatum laterale, 6 in number; by Jackson and Gowers, Pooley, Dreschfeld (3 cases), and Rosenbach.

d. Cases of lateral hemianopsia from lesions chiefly or exclusively involving the white substance of the

Digitized by Google

occipital lobe, 11 cases; by Levick, Hosch, Baumgarten, Dmitrowsky and Lebeden, Westphal (1881), Senator, Sturger (Case VII.), Wernicke, and Hahn, Jany, Richter, and Schmalz.

e. Cases of lateral hemianopsia of external or traumatic origin, 5 cases; by Keen and Thompson; reëxamined by Dr. Seguin, Hughes, Schmidt, Rimpler, Heuse, and Nieden.

f. Cases of lateral hemianopsia, due to lesions involving the cortex of the brain and subjacent white substance, 13 cases; by Westphal (1882), Stuger (Case VIII.), Förster, and Wernicke; Jastrowitz (2 cases), Curschmann, Nothnagel, Marchand, Chillou, Haab, Huguenin (1882), Féré, and the author's case.

This last category being by far the most important for the study of the localization of the visual centre in man, Dr. Seguin gave full abstracts of all these cases. The lesions in all were so placed as to cumulate toward the mesial aspect of the occipital lobe.

This result was shown by means of a shaded chart, consisting of a diagram of the mesial and lateral views of the brain, upon which the lesions of the thirteen cases were reproduced with one layer of India ink. The result was strikingly visible in the great blackness of an area upon the mesial aspect of the cerebrum, including the lower part of the cuneus and the fifth temporal gyrus (Ecker).

To this locality, also, was limited the lesion found in the following cases: Haab's, Huguenin's, Féré's, and Seguin's. These were single lesions, and no paralysis or anæsthesia had been observed during the patient's life—only hemianopsia.

Dr. Seguin's own case was as follows: A man, æt. 46, affected with malignant endocarditis (mitral vegetations), which proved fatal in sixteen months from first observation in January, 1884, through repeated visceral embolism. The case also exhibited for many weeks an exquisite intermittent form of fever, closely imitating malarial intermittent.

About December 5, 1884, Mr. D. suddenly complained of "blindness of the left eye," and slight numbness through the whole left side of the body. He strongly insisted then, and frequently thereafter, that his left eye was alone affected, because he could not see to his left. Examination showed well-defined left lateral hemianopsia, the vertical line passing a little to the left of the point of fixation. In a short time the numbness passed away, but the hemianopsia persisted until death. For many months before death Mr. D. was able to read and write easily and attend to business outside, in spite of the hemianopsia.

The lesion found at the autopsy was a large old patch of yellow softening, involving the greater part of the right cuneus, almost reaching the apex of the occipital lobe, and the fifth and fourth temporal gyri, extending also front and into the gyrus hippocampi. This lesion was found to be due to blockade of the occipital artery, branch of the posterior cerebral. The white matter was involved to a depth of several millimetres.

No sections were made in the fresh state of the specimen, in order to prepare it for more careful examination when hardened. Unfortunately, this process was unsuccessful in part, and only the occipital end of the brain became hard. The absence of decided motor and sensory symptoms during life, however, makes it quite certain that there were no other gross lesions in the brain.

From these four cases, supported by the cumulative evidence of all the others, Dr. Seguin considered it as well proven that the visual centre (receiving impressions from one corresponding half of each retina) in man is in the cuneus and adjacent gray matter below it. A destruction of this part of the hemisphere inevitably produces lateral hemianopsia of the field on the opposite side of the body.

As regards those few cases in which the lesion causing lateral hemianopsia is situated upon the lateral aspect of the hemisphere, in the inferior parietal lobule and the gyrus angularis, Dr. Seguin called attention to the fact that the optic fasciculus of Gratiolet and Wernicke, on its way from the primary optic centres, latter end of the posterior horn of the lateral ventricles to the cuneus, passes close under these gyri, and a lesion which penetrates at all beneath the gray matter of their cortex must intercept, by pressure or by destruction, the optic fibres. These are lesions intercepting communication between the eyes and the visual centre, while lesions of the mesial aspect of the occipital lobe destroy the centre itself.

DR. T. R. POOLEY said that, without knowing at all the direction which Dr. Seguin's paper would take, he had hastily looked over his records, and briefly abstracted five cases of hemianopsia, of which he had notes. One of these cases is the case referred to by Dr. Seguin in his paper. He felt quite incompetent to discuss the physiological and theoretical question as to the location of the lesion, and the importance of different symptoms in helping us exactly to locate the lesion in the brain. Nor would he at this late hour refer to all the cases of which he had intended to relate somewhat in detail the clinical histories. He would content himself with speaking only of one case which has recently come under his observation, and which is now under treatment. It is a case which he saw a week ago—that of a gentleman aged 35, who came under his care in 1879 for comparative blindness of his left eye, which he found to be due to circumscribed choroidal exudation situated near the macula lutea. In his former experience with such cases, he always believed them to be due to syphilitic infection, and careful inquiry into the history of this case showed it to be also due to this poison. The patient remained for a time under treatment for this inflammatory exudation, from which he recovered with a scotoma, and enjoyed comparatively good health and freedom from all further syphilitic manifestations until a week ago, when he consulted Dr. Pooley again.

On this occasion the patient was driving with his wife in the country, and suddenly became perfectly blind. This blindness lasted for but a few moments. Upon recovering, he ascertained that there was dimness of vision upon the left side, which continued until he came to see Dr. Pooley. Examination showed left homonymous hemianopsia, the blind area extending almost to the point of fixation in each eye. Examination of acuteness of vision showed in the left eye (and this is interesting because of the previous condition of the eye) $\frac{22}{C}$; the right eye, $\frac{20}{XX}$, or perfect. The optic disks were quite

Digitized by Google

normal; the bloodvessels were of full size; there was no indication of atrophy of the optic nerve by neuritis.

The interesting and remarkable fact in this case, is the improvement which took place within a week from the commencement of treatment. On account of the previous history of the case the patient was placed upon large doses of iodide of potassium. Former experience with the use of the drug, however, led Dr. Pooley at first to give comparatively small doses, only fifteen grains. But he found that the patient tolerated large doses much better than he did small ones, and he immediately began pushing the remedy, so that he gave him one drachm three times a day by the third day. Already upon the first day after treatment had been begun the visual fields had increased in extent, and this increase in the visual field has steadily continued until the present date. Unfortunately he had not had opportunity to make measurements with the perimeter, the patient being treated at his home, but he might estimate that the field of vision has extended from near the point of fixation to one-third the normal limits, the increase being apparently symmetrical. He should like very much to have Dr. Seguin's opinion as to whether in a case of this kind, in which there has been such marked improvement within a week's time, we may hope for permanent benefit.

DR. M. A. STARR thought that the list Dr. Seguin had presented is a complete one with perhaps a single exception, that of a case presented by Demange, in the *Revue de Médecine* for May, 1883. That case is referred to by Dr. Gowers in his last work on *Diseases of the Brain*, in a way to lead one to suppose that it supported the assertion of Ferrier, that the angular gyrus is the centre for vision. He has found, however, on looking up the case, that the lesion was one which coincided very largely with that of the first case of Westphal, and is very well represented by the diagram shown by Dr. Seguin of that case. It was a very large lesion, involving both parietal lobules and the occipital lobe. Gowers refers to that case as proving that a lesion upon one side of the brain may produce blindness of the opposite eye, and says it supports Ferrier's assertion of amblyopia being due to lesion of one angular gyrus. In the original report, however, it is only stated that the patient could not see well with the left eye, and it does not state that there had been any careful measurement of the field of vision. Therefore, in all probability, the patient had hemianopsia, and as in a number of cases reported by Dr. Seguin, and in a number which he himself had collected, lack of careful observation on the part of the examining physician failed to elicit the symptom, which was undoubtedly present. The necessity for careful examination in all of these cases has been dwelt upon by Dr. Seguin, and he thought it ought to be emphasized, because it is evident, from the history of these cases, that a patient with hemianopsia does not notice the exact field of vision, but only notices that he is blind in one eye, and refers it to the eye whose field of vision is most largely implicated. The necessity for such an examination is shown in the fact that Dr. Seguin has been able to collect eight cases in addition to those which he had collected—that is to say, eight new cases have occurred since January, 1884. This great increase in the number of cases of hemianopsia is only apparent, few cases having been recorded previously because of imperfect examinations of the visual field.

He would not anticipate Dr. Seguin in answering the question asked by Dr. Pooley, but he had in his hand a case published by Baer in Volkmann's *Sammlung klinischer Vorträge*, which is almost identical with that related by Dr. Pooley this evening: a case of hemianops a coming on suddenly in a syphilitic individual; a se ies of diagrams are given, showing the progressive improvement of the patient, and final complete recovery.

His attention was first called to this subject three years ago, by seeing a case of hemianopsia in Charcot's wards, and in his lecture on that case Charcot virtually retracted his own diagram and adopted one like that shown by Dr. Seguin. So that, he thought, we should cease to copy the old diagram made by Charcot, as it has been abandoned in France and Germany.

The absolute necessity for such a collection of cases as Dr. Seguin has made for settling any disputed question of localization is perfectly evident to all. It is the only way in which this question of localization can be really determined. To make conclusions from physiological experiments, he thought, is no longer warranted. We must go to carefully made autopsies.

It may be interesting to know that in October, 1858, the Pathological Society of Philadelphia discussed the subject of abscess of the brain, and at that meeting Dr. Weir Mitchell presented a case with the records, in which a large abscess at the posterior part of the brain, involving both occipital lobes, was attended with blindness, and the blindness seemed to be the chief *local* symptom (as we should say now) of the disease. The Pathological Society were at a loss to explain the occurrence of blindness with this lesion in the occipital lobes. Dr. Starr thought that it was encouraging to the general cause of clinical diagnosis that now, after the lapse of these years, we are able to explain perfectly that case which then so puzzled the Pathological Society of Philadelphia.

DR. SEGUIN closed the discussion, and apologized for having detained the Society with so long a paper. With reference to Dr. Pooley's question, he would have to decline to answer it for want of experience. He had never seen a case of hemianopsia which was not embolic or possibly due to a tumor, and in which there was no indication for treatment.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, October 27, 1885.

THE PRESIDENT, ROBERT F. WEIR, M.D., IN THE CHAIR.

SIMPLE FRACTURE OF THE PATELLA TREATED BY WIRING THE FRAGMENTS; SECOND FRACTURE TREATED BY SUTURING THE FRAGMENTS WITH CATGUT; FALSE MEMBRANES WITHIN THE JOINT SEEN AT THE TIME OF THE SECOND OPERATION.

DR. L. A. STIMSON presented a man, twenty-one years of age, in whom he had had the opportunity of observing the condition of the knee-joint two and a half months after the patella had been wired for a simple fracture. The patient came to Bellevue Hos-

Digitized by Google

pital last June with simple fracture of the patella, and was treated by one of Dr. Stimson's colleagues, by making a transverse incision and wiring the bone with silver wire, two sutures being inserted. The case did perfectly well, and the patient recovered without any elevation of temperature or manifestation of trouble in the joint. When Dr. Stimson first saw him, two and a half months after the operation, the fragments were closely united without independent mobility, and the patient was walking about the wards with a condition of the knee which allowed the joint to move through the arc of a circle about twenty degrees. About one week afterward, while descending the stairs, without falling, stepping down with the sound leg forward, he fractured the patella which had been broken. Previous to the accident Dr. Stimson had noticed what seemed to be one of the wire sutures, which could be felt under the skin, and the patient had felt a slight pricking pain at that point throughout the progress of the case. In the second fracture the old cicatrix was torn open. Dr. Stimson enlarged the wound and found that the second fracture had taken place exactly in the line of the first; one wire was entirely, the other almost entirely, loose in the wound, and the site of each was marked by small cavities in the fragments. The surfaces of fracture were not so rough as usual, and Dr. Stimson thought that union had taken place, in part at least, by a very thin intermediate layer of fibrous tissue. On the inner corner of the upper fragment, where in the first fracture there had been a small loss of tissue, there was a distinct fibrous band as large as his little finger. On wiping out the blood he saw a membrane of new formation underlying the patella and entirely separating the fracture from the cavity of the joint, except at one point where it was torn for half an inch; through this opening he was able to see false membranes within the joint connecting the condyles of the femur with the tibial head. He cleansed the wound, brought the fragments together with catgut, closed the wound, and the patient is now well. The fragments have again united, and there is some motion in the joint. It is now two months since the second fracture.

The reason Dr. Stimson reported the case is because he saw not long ago the statement that there was no case known where any membranes of new formation had formed in the joint after wiring the patella for simple fracture. But this joint was full of them, and they had formed without any inflammatory reaction, or any symptoms indicating these formations.

Again, it has been claimed that a patient with a fracture of the patella, treated by wiring, can be dismissed cured at the end of four weeks. Dr. Stimson did not know of any other similar fracture which is perfectly sound at the end of so short a period of time; but here is a case in which two and a half months have elapsed since the fracture, which has done well, and which, if reported two or three months ago, at the stage at which most cases have been reported, would probably have been cited as another example of the safety and value of the method of treating by wiring; and yet the union proved to be not strong enough to bear the weight of the body in descending stairs, and the joint did not allow of more than twenty or thirty degrees flexion.

DR. BRIDDON asked whether catgut had been used for this purpose before.

DR. STIMSON said he had used it in operations upon joints several times. He thought it would last probably three weeks.

DR. W. T. BULL asked, What is the ultimate prospect, so far as motion is concerned, in this joint?

DR. STIMSON answered that it is poor.

DR. BULL asked whether that is not the average in all cases in which the patella is wired.

DR. STIMSON said he had not seen good motion in any case, but it had been reported that the operation gave good motion.

DR. POST asked, when the choice is between a stiff and a weak joint, whether the stiff joint is not to be selected.

DR. BULL thought it is.

THE PRESIDENT said, Is it not true, also, that, after fracture treated by the ordinary method, better results are obtained than in the joint of the patient presented?

DR. STIMSON replied that a good deal better result was obtained.

TUBERCULAR DISEASE OF THE TARSUS; RESECTION OF ASTRAGALUS AND SCAPHOID BONES.

DR. W. T. BULL presented a young woman, in order to show the result of an operation which was performed eighteen months ago. She presented herself at the New York Hospital on the 17th of March, 1884, with the history that she had been in somewhat delicate health, having had cough, but no hæmoptysis. Seven weeks before admission she complained of lameness in the right foot, and inability to walk without considerable pain. The motions of the ankle were nearly perfect. The only evidences of disease of the bones of the tarsus were a decided tenderness over the scaphoid, and a slight swelling below the ankle; and, besides, there was atrophy of the calf upon that side to the extent of being one inch smaller than its fellow. For seven weeks the foot was treated with plaster-of-Paris splint and applications of oleate of mercury, thermo-cautery, belladonna liniment, etc., without improvement. Dr. Bull then made an incision upon either side of the ankle and removed the astragalus and scaphoid bones. He did not detect any indications of tubercular disease of the synovial membrane, but the bones were softened. They were removed entirely with knife and scissors. The wounds healed promptly, with the exception of the sinuses left by the drainage tubes, which were somewhat slow in closing. In about a month she was able to walk about and bear some weight upon the foot, but it was with considerable pain. Five months later he discovered a good deal of tenderness over the os calcis and suspected similar disease of that bone; and, although the motions within the ankle-joint were quite good, he introduced a drill by means of the dental engine into both malleoli and also into the os calcis. In the former he found no evidence of disease, but in the latter he found a soft spot which he drilled out and treated with iodoform, and it healed promptly. This operation was performed eight months after the first one, and since that time the pain in the ankle and foot has gradually disappeared. Now the functions of the foot seem to be perfectly performed, and the only deformity is a shortening of the foot by about one inch. The calf of the leg has increased in size until it is only one-half an inch smaller than the other.

Digitized by Google

Unfortunately, to make the diagnosis positive, the bones were lost, and therefore not examined for micro-organisms; and, although they did not present to the naked eye any of the characteristic appearances of tubercular lesion, Dr. Bull felt warranted in believing that the disease was of that nature.

It may be remembered that, at the meeting of the Society last spring, he presented a patient, an Italian, from whom he had removed the entire tarsus for tubercular osteitis, and the result did not seem to be satisfactory, as the man experienced some pain in walking. His condition has improved materially since that time, and he is able to do all sorts of active work without discomfort.

DR. H. B. SANDS thought that the results in cases of excision of the tarsal bones are usually better than may be anticipated; and the observation made by Dr. Bull, that the patients continue to improve for a considerable period after the operation accorded with his own experience. In cases of tubercular disease of the joints in which operations for the removal of a diseased bone are performed by means of a sharp spoon, he supposed that frequently a sufficient amount of periosteum is left to reproduce, to a considerable extent, the bone removed, and in this manner to contribute to the stability of the foot. He had repeatedly noticed, after dealing with the tarsal bones, and also after removal of the carpal bones, that, although a large portion of osseous tissue was removed, after the lapse of six months or a year, the parts become so firm that one could hardly believe that such an amount of bone had been taken away.

DR. C. T. POORE, in cases occurring in children where he had endeavored to remove the os calcis and leave a portion of the bone with the periosteum, had subsequently been obliged to remove the entire bone because of non-closure of the wound, and because the disease was extending to other bones. In one case he was certain that he left the anterior portion of the bone undisturbed. Eight or nine months after the first operation he found the cavity, as it were, of the os calcis filled with dense fibrous tissue. In children he had not been able to save any of the bone, but had removed everything, and the results had been very good.

CORRESPONDENCE.

THE REPORT OF THE MEETING OF THE COMMITTEE ON THE INTERNATIONAL MEDICAL CONGRESS.

To the Editor of THE MEDICAL NEWS.

SIR: My attention has just been called to a criticism in the *Association Journal* of October 31st, by an officer of the ex-Committee of Arrangements for the International Medical Congress, of a letter of my own, which appeared in your issue of October 10th.

The effort reminds me so much of a cobbler striving to patch with flimsy material his originally bad work, that I might complacently afford to stand in my old shoes. But for the benefit of my professional brethren, who may, through inadvertence, be deceived, I will notice only the two points in the criticism which may seem to affect my position. My letter stands as the public record of my action in the Committee.

1. I am accused of having "persistently endeavored to obstruct the proceedings of the Committee" (at the meeting in New York, on the 3d and 4th of September), "by frittering away valuable time with trivial objections." These objections of my own are on record, and need not be defended. No doubt they were annoying to some. But the author of the complaint has inadvertently paid me a very great compliment, for which I am grateful. To "obstruct proceedings" which I have shown to be irregular and prearranged by certain parties to advance their special ends, regardless of the unity, harmony, and well-being of the profession, can only be regarded by proper thinking persons as a meritorious act.

2. Next it is stated that I complained that "a letter which he (I) forwarded to the Temporary Secretary was not read before the meeting of the Committee in Chicago, or embodied in the report which was recently published." My letter is referred to as on a par with two hundred letters received from other parties (not members of the Committee), to have read all of which would have occupied the entire day. The Committee, it is stated, only directed that a letter from Dr. Austin Flint, Sr., should be read.

The above is not a correct statement of facts. I was, together with Dr. Austin Flint, a member of the Committee of Arrangements, and did not, therefore, occupy the same position with two hundred persons who may also have written letters, but who were outside of the Committee. I had, therefore, equal right with Dr. Flint. As a member of the Committee, unable to attend the Chicago meeting, I sent my letter addressed to both the Chairman and Secretary, waiving the fact that they had usurped their positions. I had an equal, if not a better right than Dr. Flint to express my views by letter. He was represented by a proxy. After this proxy took his seat in the Committee, Dr. Flint was, for the time being, not a member of the Committee. But, further, the proxy was there to step in as a permanent member of the Committee when Dr. Flint, in accordance with previous arrangement, stepped out. Possibly, as I was not connected with this or any other previously arranged programme, my letter was unimportant, and Dr. Flint's alone was accorded a reading. Had I occupied a like distinguished position in the eyes of the managers, or been as available for promotion from the ranks of the Committee to the highest office in the Congress, I might have been accorded equal rights with my illustrious friend.

Still, I am satisfied with my present humility, and would not exchange this for the highest office bestowed by the Committee.

No further rejoinder from the same source will induce me, Mr. Editor, to trespass again on your columns.

R. A. KINLOCH,
Member of Committee from South Carolina.

CHARLESTON, Nov. 7, 1885.

NEWS ITEMS.

WASHINGTON.

(From our Special Correspondent.)

CHOLERA IN SHANGHAI.—The U. S. Vice-Consul-General at Shanghai, China, informs the Department of State, under date of September 10, 1885, that at his re-

Digitized by Google

quest Dr. Neill Macleod has furnished him with the following information:

"During the last week in August, the deaths from cholera in the English and American settlements are reported to have been 96 amongst the Chinese. The returns for September have not been sent in, but I think the number is not probably less. The deaths among foreigners have not yet, I believe, exceeded 10. We have no means of determining the number of cases."

The Vice-Consul is advised by the Superintendent of Police, and by the Chinese officials, that in the native (old) city of Shanghai and its suburbs, with an estimated population of over 300,000, which is not referred to in Dr. Macleod's communication, the cases of cholera are exceedingly numerous, but no statistics are obtainable.

He says the walled city of Shanghai is the filthiest city he has ever visited. Old residents of China have informed him, that it is considered to be at the head of the list of Chinese cities, so far as filth and vile smells are concerned. A few days ago, he says, he made a tour of inspection through the city, and found vegetable and animal garbage festering on every hand. All human excrement is carried out of the city, to be used in fertilizing the fields, and as it is carried through the streets in open buckets, the air is constantly charged with vile odors, and besides this, numerous public latrines are scattered about, and the temporary occupants are in full view of passers-by. The latrines are rudely constructed, and no attempt made to disinfect them, and there is no doubt that they are the direct cause of a great amount of sickness. The streets are narrow, and the dwellings low and damp. The Vice-Consul-General thinks the only wonder is, that the mortality is not greater than it is.

MONTREAL.

(*From our Special Correspondent.*)

THE SMALLPOX.—During the last few days the daily mortality from this disease has fallen from 50 to 40. The isolation committee is doing good work and all houses and tenements where smallpox cases are found are carefully guarded. Where isolation is impossible, the patients are removed to hospitals. The patients as a rule go quietly, but if they refuse, force is used. A few days ago it took the Mayor and fifty policemen to remove two cases from a house defended by a father and son with shotguns and revolvers; the cases were successfully removed without any mishap. For this action the Mayor was much abused by the French papers. The new hospital is already full and more hospital accomodation is being provided; vaccination is still hanging fire, and the great mass of people in the east end still remain unvaccinated, preferring death from smallpox to dishonor from vaccination.

The deaths during October in Montreal and suburbs have been 1630 in number; of these 1599 were Catholics and 31 Protestants. The Catholics were mainly French, the mortality amongst the Irish Catholics (who are well protected by vaccination) not being more than amongst the Protestants. Since the commencement of the epidemic there have been 2641 deaths from smallpox.

A GERMAN OPINION OF THE CONGRESS IMBROGLIO.—It is known that the invitation of the American medical profession, extended by Dr. Billings, Surgeon U. S. Army, at Copenhagen, last year, was accepted. The Committee of Organization consisted of Drs. Austin Flint, of New York, President; J. S. Billings, of Washington, Secretary-General; I. Minis Hays, of Philadelphia; Lewis A. Sayre, of New York; Christopher Johnston, of Baltimore; George Englemann, of St. Louis; A. Jacobi, of New York; and other prominent members of the medical profession in the United States. These gentlemen set about their work with great zeal, put in motion the organization extremely difficult to arrange, named the several secretaries and other officers, and distributed in April of the present year a pamphlet in which the rules regulating the organization of the Congress and all facts of special interest relative to it were set forth. From this the impression was gained that the profession in its entirety would be represented in the Congress, as a national body, which should include all medical societies and bodies with common and special aims.

Now, while the gentlemen composing the original Committee were chosen from the American Medical Association and entrusted with proper powers, it happened at the meeting of this Association, held this year at New Orleans, certain intriguers and office-seekers, at the head of which was Dr. Shoemaker, of Philadelphia, set aside the regulations adopted by the original Committee, and named a new Committee, more numerous and containing a part of the old Committee, and representative only in a territorial point of view. In order to understand this step, it must be recognized that the American Medical Association, especially those who in it exercise the greatest authority, lay especial stress upon geographical representation—*i. e.*, that on all special occasions each of the separate States shall have equal representation; and, further, that the American profession is divided into two great parties, representing, respectively, the old and the new Code of Ethics, which differ, especially in the regulations relative to irregular practitioners, the old code maintaining a strict, the new a lax, stand toward them.

As the original Committee did not conform their action to the demands for territorial representation, or act wholly in the interests of the old and stricter code, it came to pass, through the skilful use of both these levers, that the above step was taken—*i. e.*, the organization of a new Committee. Naturally, the old Committee resigned.

It has been repeatedly said, and we, ourselves, hold the opinion, that scarcely a prominent member of the German profession can be found who would be willing to go to America to sit under the presidency of Dr. Shoemaker, and participate in a disintegrated and destroyed Congress. The old Committee, part of which is personally known to and respected by us, has our entire support. If we, hitherto, have refrained from noticing this family embroglio, it was in the hope it would finally be righted in a manner satisfactory to all.

Indeed, even now it does not seem too late for this to be accomplished. Next spring the American Medical Association again meets. Let it do so with the understanding that it is no disgrace, and never too late, to recognize and rectify a wrong, and to bestow upon the original Committee a vote of confidence, and restore them to authority. We are convinced from the high

Digitized by Google

position and zeal of these gentlemen, that they would rise above the wrong done to them; but, on the other hand, we have every reason to assume that under the existing conditions the Congress will be a total failure.—*Berliner klin. Wochenschrift*, October 26, 1885.

AN ENGLISH OPINION OF THE CONGRESS CONTROVERSY.—Those of our English readers who have followed with painful interest the course of the struggle now in progress in America with regard to the Washington Medical Congress of 1877, will be amused to hear that the new executive committee of the Congress have resolved that their actions "*are final, not being subject to revision, amendment, or alteration by either the Committee of Arrangements or the American Medical Association.*" The astuteness of that resolution is as remarkable as the irony of it is delicious. If the original committee had only been wise enough, before the event, to have adopted such a decision, there would have been none of the dissensions which have so terribly distracted the American profession. The resolution is at once a slap in the face to the American Medical Association and a sneer at the original committee of eight, as if to say, "Why, what idiots you were, not to have thought of this!" And yet it is at the same time a score to the original committee and its supporters in that it is a justification of their action in resenting the interference of the Association with their decisions.

Meanwhile we hear affairs are *in statu quo*. The resignation of Dr. Dalton, the Chairman of the Physiological Section, which has happened since we last wrote on the subject, leaves the organization of the Congress without a single really scientific representative if we except the Flints and Dr. N. S. Davis. If the meeting is held, the Sections of Anatomy, Physiology, and Pathology will not be attended by any of the American workers in those fields. There is, we fear, little hope now of an arrangement. All the prominent American men of science have withdrawn, and will not return unless very considerable concessions are made, of which there appears no hope.

The *Berliner klinishche Wochenschrift* this week roundly states that hardly a single "medical personage" will be found to undertake the voyage from Germany for the privilege of sitting under the presidency of Dr. Shoemaker. It makes, however, a strong appeal to the American Medical Association to approach the subject in a more wise and generous spirit when its next Spring assembly takes place, and to rearrange its propositions in such a manner that the services of the leaders who were nominated in the first instance may still be made available. In the absence of such a rearrangement, our Berlin contemporary expresses a decided opinion, which we can heartily endorse, that the Congress of 1887 will be foredoomed to dismal failure. The whole thing is a bad business. It is an awkward position, for it must be remembered that the Washington Congress will have to make arrangements for the succeeding meeting. Suppose Dr. Shoemaker and his friends decide that the Congress of 1890 shall be held in Texas.—*Medical Times and Gazette*, October 31, 1885.

HOME OPINION ON THE CONGRESS ORGANIZATION.—That the Association had full power to revise the work of its committee we feel assured. This prerogative still exists, notwithstanding the rather singular assumption by the Executive Committee of the Committee of Arrangements, that its action was final, "not subject to revision, amendment, or alteration, either by the Committee of Arrangements or the American Medical Association." We would quote from an editorial in the Association Journal of June 6th: "The idea that the powers and duties enjoined upon a committee of arrangements, appointed by a permanently organized association, are in the nature of *vested rights* by which such committee becomes an independent body, self-perpetuating, and responsible to no one, has not hitherto been widely entertained in this country." This action cannot have the support of the Committee of Arrangements, which still holds to the idea of its responsibility to the Association.—*Mississippi Valley Medical Monthly*.

Probably one most startling event in the whole history of this most miserably bungled affair is the resolution passed by the Executive Committee appointed by the Committee of Arrangements two months ago. We certainly admire this bold piece of policy on the part of the Executive Committee, but hardly find it consistent with the opinion which the American Medical Association obtained from Ex-Speaker Randall, and with which they sought to justify their action at New Orleans: ". . . The theory that a select committee, created by a body with certain defined powers and duties, gives any *vested rights*, so to speak, which place it above or beyond the power of the creating body to review or regulate, is one not only without precedent in parliamentary law, but is untenable on any ground of parliamentary principle."

Here we have a committee declaring itself to be irresponsible, a servant without a master. This combination calmly asserts that it is going to do the work, and that the Congress and profession generally will accept and approve of that work, whether they like it or not. Out in California we have had some experience of Vigilance Committees in troublous times, who were invested by the citizens with full power to use all means to quell the disturbance, and this is the only irresponsible committee known in this State. Possibly this Executive Committee is of that nature.—*Pacific Medical and Surgical Journal*.

HOW SMALLPOX HAS BEEN INTRODUCED INTO THE UNITED STATES FROM CANADA.—The Secretary of the State Board of Health of Michigan, in a circular letter to the Health Inspectors of Travel, says: About August 6, 1885, a French-Canadian family, consisting of the mother and six children, passed through Port Huron from Montreal to Marinette, Wisconsin. They met with no detention at Port Huron, or at any point through Michigan, Illinois, or Wisconsin, as it was before the present system of inspection was established. From this family resulted eighteen cases of smallpox, with four deaths. The outbreak was promptly suppressed by the health authorities at Marinette.

Another French family, named Picher, left their home near Montreal, September 22, 1885, were detained at Detroit, "examined, fumigated, and vaccinated." The family consisted of father, mother, and seven children. They passed Detroit, September 23d, and reached their destination near Coleman, in the Township of Peshtigo, Wisconsin, on the night of September 24th. About a

Digitized by Google

week after their arrival in Wisconsin, four of the children were taken sick with smallpox, but it was not discovered until a large number had been exposed. I am informed by J. J. Sherman, M.D., health officer at Marinette, Wis., that "the vaccination at Detroit was complete and effective on three, and greatly modified the attack on the other four."

Dr. Sherman, writing October 30, 1885, in regard to these cases, says: "Of course it does the immigrant good to vaccinate, and no doubt prevents the spread of smallpox altogether in many cases, . . . only I do think that immigrants from infected districts should be held, when they have not been vaccinated or had smallpox until the vaccination gives evidence of working, or until it is morally certain that the disease is not in the incubative stage; and, if possible, notices forwarded to health officers of the towns to which they are going, that they may be kept under surveillance until all danger of contagion is passed."

THE INTERNATIONAL CONGRESS AND COLLECTIVE INVESTIGATION OF DISEASE.—The preliminaries for this investigation are, as announced from London, so far advanced, that inquiry lists will shortly be ready for transmission. These will again be collected at the close of 1886, and the materials put in such shape that the results of the investigations may be communicated to the next meeting of the International Medical Congress.

MEDICAL DISPENSARY SERVICE FOR THE INSANE POOR OF PHILADELPHIA.—At a recent meeting of the Managers of the Pennsylvania Hospital, it was determined to add to their Outpatient Department, on Spruce Street, near Ninth, a medical service for the purpose of furnishing advice and treatment to persons suffering from the early or incipient symptoms of insanity, but who may not require the custodial care of a hospital. Cases of chronic or established insanity will not be received.

The service is designed for the benefit of persons in indigent circumstances, and for the present will be rendered by the physicians of the Department for the Insane of the Pennsylvania Hospital. Dr. Henry M. Wetherill will be in attendance at the Outpatien Department on Monday and Friday of each week, at 3 P.M., during November and December, commencing November 2.

CINCINNATI COLLEGE OF MEDICINE AND SURGERY.—Dr. Charles E. Caldwell has been elected Lecturer on General Pathology in this institution.

OBITUARY RECORD.—DR. WILLIAM BENJAMIN CARPENTER. The death of this eminent English physiologist is announced by a cable from London last Tuesday.

Dr. Carpenter was born in Exeter, October 29, 1813. In 1834, yielding to the desire of his family that he should study medicine, he went to London, where he pursued his studies at University College and Middlesex Hospital, and there, while attending the lectures of Dr. Grant on comparative anatomy, he laid the foundation for his works on physiology, by which he is most widely known.

Passing his examination at the College of Surgeons and Apothecaries' Hall, he went, in 1835, to Edinburgh to pursue his professional studies, and while there was elected the first of the four annual Presidents of the Royal Medical Society. Shortly afterward he accepted the lecturership on medical jurisprudence in the British Medical School, and about this time he began to write his now universally known treatise on *General and Comparative Physiology*, the first edition of which appeared in 1838.

Dr. Carpenter's natural bent leading him rather to the scientific than to the practical aspects of medicine, he now resolved to devote himself wholly to the study of physiology, lecturing, private tuition, and writing, and henceforth he was known not only as a systematizer of the works of others, but as an independent, original, and scientific investigator.

Dr. Carpenter was at one time Editor of the *British and Foreign Medico-Chirurgical Review*, and contributed articles to that journal on a wide range of subjects.

Besides his treatise on physiology, Dr. Carpenter produced numerous other scientific works, among which are a study of the Australian and Philippine *Foraminifera*, discussions of the phenomena of mesmerism, hypnotism, and *The Microscope and its Revelations*.

Later in life he was occupied in investigations connected with the deep sea dredging expeditions.

Dr. Carpenter's death occurred as the result of an unfortunate accident, and was due to burns caused by the upsetting of a spirit lamp, while he was taking a vapor bath for rheumatism, to which he had long been subject.

NOTES AND QUERIES.

A LONG UMBILICAL CORD.

To the Editor of THE MEDICAL NEWS.

SIR: As a matter of perhaps some statistical interest, I wish to place upon record the measurement of an umbilical cord at full term, which exceeds in length any previous published contribution upon the subject of which I have any knowledge. It measured three feet and four inches, and, but for the fact that it encircled the child's neck twice and body once, I should probably have had a case of umbilical hernia to contend with. Respectfully,

A. H. GARNETT, M.D.

OSWEGO, KANSAS, Nov. 2, 1885.

CASE OF TOTAL ABSENCE OF VAGINA.

The case of total absence of vagina noticed in our issue of last week, page 515, was under the care of Dr. Joseph Eastman, of Indianapolis, Indiana, and the case is still under his observation.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM NOVEMBER 3 TO NOVEMBER 9, 1885.

MCCLELLAN, ELY, *Major and Surgeon.*—Leave of absence granted in orders, Cavalry Depot, Jefferson Barracks, Missouri, October 30, is extended seven days.—*S. O. 254, A. G. O.*, November 4, 1885.

KANE, JNO. J., *Captain and Assistant Surgeon.*—Ordered for duty as Post Surgeon, Fort Ringgold, Texas.—*S. O. 141, Department of Texas*, November 4, 1885.

EBERT, A. G., *Captain and Assistant Surgeon.*—Ordered from Camp Grant, Riverside Park, New York City, to Fort Hamilton, New York Harbor, for duty.—*S. O. 237, Department of the East*, November 5, 1885.

BUSHNELL, G. E., *First Lieutenant and Assistant Surgeon.*—Assigned to duty at Camp Grant, Riverside Park, New York City.—*S. O. 237, Department of the East*, November 5, 1885.

ORIGINAL LECTURES.

AN UNUSUAL CAUSE OF CHRONIC LEAD POISONING.

A Clinical Lecture Delivered at the Pennsylvania Hospital, October 24, 1885.

BY ARTHUR V. MEIGS, M.D.,
PHYSICIAN TO THE HOSPITAL.

(Reported by Charles Baum, M.D.)

GENTLEMEN: As a clinical lecturer, I shall teach you most by showing you ordinary cases of disease, such as you will be called upon to treat when you become practising physicians, but occasionally there are in the wards of the hospital cases of rare disease or unusual phases of common ones, by showing you which I may perhaps impart to you as valuable information. Some of you may perhaps never meet with a case such as I shall now describe, but if you should, the information I shall impart to you may prove of value.

A week ago to-day I found in our waiting-room a man who wished to be admitted to the ward. I can perhaps best explain to you the method by which I arrived at the diagnosis in his case by telling you the impression his condition produced upon me when I first saw him: He was seated upon a bench looking very pale, and with an expression of great pain upon his face, and when I asked him what was the matter, he said he had violent pain in the abdomen. I then asked to see his tongue, and when he protruded it I noticed that the breath had a heavy, disagreeable odor. Something in his appearance having now aroused my suspicions in the right direction, I questioned him in regard to the condition of his bowels, and upon learning that he had had no passage for five days and had been constipated for some time past, it was only necessary for me to ask him to set his teeth together so that I might examine his gums and teeth to establish at once the diagnosis. There was upon the gums of both the upper and lower jaws the characteristic blue discoloration of lead poisoning. This blue discoloration, you must remember, is upon the gums and not upon the teeth, and you must never allow yourselves to be deceived into mistaking the blue color which the tartar upon the teeth of those who are not cleanly about their mouths often has, for the blue line of lead-poisoning. If there is ever any doubt in regard to the situation of a blue discoloration in the mouth, it is always readily dispelled by taking a matchstick or toothpick and scraping at the spot to see upon which surface it is situated, whether upon the teeth or gums, and once you have established that the blue line is upon the edges of the gums just at their junction with the teeth, there can be no doubt as to the nature of the disease with which you are dealing. Having discovered this line upon the gums, I was certain, without further inquiry into either the condition or occupation of the patient, that he was suffering with lead colic, for had he not its three most marked and constant symptoms—continued severe pain in the abdomen, obstinate constipation, and blue line upon the gums? I have already shown you this year a tinsmith who, I told you, I was satisfied was suffering with lead colic from the pain he had in the abdomen and constipation of the bowels, although there was no blue line upon the gums at all, and I was only enabled to make the diagnosis in his case from knowing that the nature of his occupation made him constantly handle lead, which you know is a large component part of solder.

Having so easily made the diagnosis, it next became a matter both of scientific interest and of importance to the patient that it should be discovered by what means the poison had been introduced into his system, for only by learning how he had been poisoned could he be warned against the danger in future. The man said he was a tailor, and had not done any other sort of work for a long time. This put me entirely at fault, especially when I found upon inquiry that nothing could be learned tending to show that his drinking-water was in any way contaminated, and as he strenuously denied using any leaden implements or handling the metal in any shape. Later I was told that Dr. H. C. Wood used to relate in his lectures at the University of Pennsylvania that he had attended sewing women suffering with lead poisoning contracted from biting thread which it was found was weighted with sugar of lead. Upon asking at a large tailor's establishment in the city, I was told that much of the silk used by them is treated with sugar of lead to give it the desired weight, and then Dr. Penrose, the resident physician, found in the *Half-Yearly Abstract*, for 1866, July to December, an article by M. Chevallier, giving an account of how thread was treated with lead, and of how women using it suffered from lead poisoning. I had intended to obtain some of the thread with which this man worked, and yesterday he was allowed to go out of the hospital to procure some of it for us, but he has not returned. I shall, therefore, be unable to do what would have been most satisfactory, examine the thread and demonstrate its containing lead. The cause of his attack of lead colic has been, however, sufficiently made clear to you from what I have told you; that the disease has been produced in the same way before from the use of thread which had been treated with sugar of lead.

The prognosis in this affection is almost always favorable, as I have already told you when I previously had occasion to show you cases of lead poisoning this autumn. Very few persons die of the effects of any of the forms of chronic lead poisoning directly, except from the encephalopathia.

With regard to treatment, the first indication to be met in a case of lead colic is to relieve the pain, which is often very severe, and this should be done before any effort is made to cure the constipation, which is also one of the most constant symptoms. To this end morphia should be given, and as much as from half a grain to

Digitized by Google

two grains will often be required in the course of three or four hours, before the pain is controlled. This patient took a quarter of a grain, and after about an hour a second quarter; at the end of another hour, the pain being still severe, he was given another half grain, and then two or three hours later the same dose was repeated. After taking this quantity—one and one-half grains—his pain was quieted, and for the first time in several days he slept comfortably. The pain having been by this means alleviated, he was given half an ounce of Epsom salts to relieve his constipation, but this amount had to be given a second or third time before the bowels moved. The two most urgent symptoms having now been disposed of, it next became proper to administer some drug which would aid nature in eliminating the poison from the system, and this is best effected by the use of iodide of potassium, which was accordingly given in ten grain doses three times daily. Under this treatment—morphia to relieve the pain, Epsom salts for the constipation, and iodide of potassium to eliminate the poison, the patient had sufficiently recovered at the end of seven days to leave the hospital, ostensibly for the purpose of procuring for us some of the thread with which he had worked, for examination, but actually, for some reason best known to himself, not to return again.

LYMPHATIC LEUKÆMIA IN CHILDHOOD.[1]

BY JOHN M. KEATING, M.D.,
VISITING OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL, BLOCKLEY, ETC.

THIS disease is interesting on account of its clinical rarity and the infrequency with which it is mentioned in current literature. There is a uniformity of composition of healthy blood which is curious. This is brought about by that equilibrium which is so striking in organs regulating the production of waste.

The blood corpuscles which we are called upon to study, are:

1st. The red, of which there are floating in the plasma about 5,000,000 to the cubic millimetre. These are about $\frac{1}{3200}$ of an inch in diameter.

2d. The white, of a diameter of $\frac{1}{2500}$ of an inch, having the proportion of 1 to every 300 or 500 red.

3d. The nucleated red, found in the fœtus and infant, and disappearing about the third or fourth year of life. These may contain one or more nuclei in some instances protruding from the cell. They measure from $\frac{1}{1400}$ to $\frac{1}{2000}$ of an inch.

4th. The hæmatoblasts of Hayem—"small discoid, colorless corpuscles, normal constituents of healthy blood—in drawn blood, they aggregate in clumps known as Schultze's granule masses." As to the origin of red corpuscles, "they are developed from colorless corpuscles, the lymph cells, or leucocytes. The nucleated corpuscles of the embryo also aid in their development. These nucleated cells disappear early in childhood, and are then found only in the red marrow." It is Osler's opinion that "they apparently originate from colorless marrow cells, which gradually become more homogeneous and hæmoglobin develops in the protoplasm, the nucleus degenerates and disappears, when the cell has the appearance of an ordinary red disk." Possibly these nucleated cells may give birth to red cells by the process of budding. The relations of the cytogenetic organs to blood formation, have always been somewhat debatable ground; the present state of our knowledge may be formulated about as follows: "The spleen certainly takes part in the development of colorless corpuscles, but its participation in red blood formation seems doubtful, though the opinion prevails widely that the spleen is one of the important organs in the formation of red corpuscles. The evidence for this belief is of an exceedingly scanty nature.

"The lymphatic glands and adenoid tissues in other regions are the seat of constant production of colorless corpuscles, but of their relation to the red corpuscles there is the same lack of information as in the spleen."

Neumann and Bizzozero pointed out the fact that the red marrow appears to be the seat of blood formation. In the adult it is the only region in which embryonic or nucleated red cells are found. In the young, the marrow fills the long bones.

It is Osler's opinion, quoting from his recent admirable articles on this subject, that the evidence of the development of red corpuscles in the marrow rests upon the constant presence of nucleated cells infiltrated with hæmoglobin, and of their fission. In excessive hemorrhage, natural or induced, it appears to undergo active proliferation, and it is an interesting fact to notice the marvellous rapidity with which the red corpuscles are reproduced after hemorrhage. The amount of hæmoglobin in healthy blood, according to Preyer, is 13.45 grammes to 100. This relation is important for us to bear in mind, as it proves an index to treatment. The color test being used, I feel certain that before long it will be a matter of more than ordinary interest to the general practitioner when the means of applying the color test shall be generally adapted, as has been partly done already, to daily practice.

In the newborn, the blood is said to amount to one-tenth part by weight of the body. In the adult, one-twelfth to one-fourteenth. It may also be noted that it has been shown by Neumann that the liver in the embryo may be the seat of the formation of corpuscles, though in the adult it is the seat of their destruction.

Let us now take up the subject of anæmia in children. We will omit that caused by hemorrhage, by toxic agents, by mineral poisons, by miasm, by syphilis, in which we have an increase in the watery elements and a diminution in the albuminous, and consider that dependent upon disorder of the blood-making organs themselves, and here we meet with a most difficult problem. By the blood-making organs we understand the spleen, the lymphatic tissues, and the bone marrow, remembering, of course, that some of these tissues have also to do with blood destruction. We, however, definitely know that an increase in the cytogenetic tissues is associated with disturbances in blood formation. The organ undergoes a

[1] Read before the Obstetrical Society of Philadelphia, November 5, 1885.

Digitized by Google

hyperplasia, particularly of its fibrous constituent, and the marrow of bone changes from normal appearance to one like spleen pulp. The blood of all patients suffering from anæmia presents a reduction in the number of red corpuscles. This is true, no matter whether the seat of the trouble is located in the spleen, the marrow of bones, or in the general lymph glands; the white cells may or may not be increased. The clinical features of a case of anæmia will be strikingly alike, let the cause be in any one of the blood-making organs; all the more important symptoms will be present. To quote once more, such common features would be "the progressive anæmia with its group of circulatory symptoms, the irregular febrile reaction, essential fever of anæmia, the absence of marked emaciation, the tendency to effusions of serum, the progressive debility, the recurrence of hemorrhages gastric and intestinal, gastric and intestinal disturbances, and the resistance to treatment."

These affections that have so many symptoms in common, are grouped as distinct diseases under the following headings, viz., Leukæmia, Hodgkin's disease (anæmia lymphatica), splenic anæmia, and idiopathic anæmia.

Leukæmia signifies a hyperplasia of the blood-making organs with anæmia and an increase in the colorless corpuscles. Of this form we have three varieties: the splenic, lymphatic, and medullary. Leukæmia is present at all ages; the youngest case recorded by Osler being an infant of eight months. The chief symptoms are, insidious onset, anæmic appearance, bleeding at the nose or other hemorrhages, frequent diarrhœa or other gastro-intestinal disturbance. The spleen is enlarged, gradually increasing in size from the onset, and finally it may interfere with the circulation, and cause difficulty of breathing by pressure. Late in the disease the liver is also enlarged. The lymph glands in most cases are affected, and sometimes slightly enlarged. The tonsils and follicles of the pharynx, are usually enlarged. The lymph glands of the intestines, and of the peritoneum, are always enlarged. Fever is present, and increases as the case progresses, and is usually of the remittent type. But the most important aid to differential diagnosis, is the microscopical examination of the blood. This I give in detail in the case that forms the basis of this paper.

I was called in consultation by Dr. J. W. Gadd, of this city, to see the child with him, in the latter part of last month, and the following notes by Dr. Gadd, have been given me:

Mamie McC., aged four years and five months, had measles when about two years old, and from which she recovered without complication or sequelæ. About August, 1884, the tissue surrounding the eye became much inflamed and swollen. The swelling increased so much that the eyelid could not be opened for several days. After continued poulticing an abscess formed and broke, discharging a quantity of pus, and continued to do so for a considerable time, but finally healed up with a small scar. The child never complained, yet was pale, and did not want to play as other children did. I believe this was due more to her disposition, than to the effect of any disease.

About midsummer there appeared a rash all over her body, very thick, and resembling the eruption of measles; as it matured, it was crowned by small white caps or heads. The epiderm soon came off in large patches. The child had no fever. As the eruption faded the mother observed purplish spots, like bruises, making their appearance. These were considered by the parents to be bruises due to falls. No attention was paid to her condition until September 28th, when I was called in the evening to arrest an epistaxis which had existed most of the day. I found the child lying on a sofa, though able to sit up, with blood slowly trickling from the nose; each nostril contained a large clot. The child appeared very anæmic with slight fever, yet did not complain of anything except weakness. The mother stated that the appetite had been very poor for some time past. The bleeding from the nose was very easily arrested by removing the clots, and packing each nostril with a strip of lint. I also gave the following internally:

℞.—Acid. gallic. . . . . gr. xxx.
Acid. sulph. dil. . . . ♏ xl.
Ext. ergot. fl. . . . . ♏ xxx.
Syrupi . . . . . f ℥j.
Aqua . . . . . q. s. ad f℥ij.—M.
Sig. Teaspoonful in water every hour. Also ordering her as much milk as she cared to take, with the precaution that she should sip it slowly.

Tuesday morning I saw her, and found her in the same condition, except that the epistaxis had been arrested. I thought it best not to remove the lint packing. It now being daylight, her mother called my attention to the bruise-like spots over her body. These were in size from that of a two-cent piece, to that of a fifty-cent piece, and two of them, situated one over each trochanter, were as large as silver dollars; with the exception of these two, they were all, I believe, situated over the soft parts, such as over the belly of a muscle, and varying in color according to age from a bluish-black to a greenish-yellow. She still had some fever, and her heart was more rapid in its action than normal; hence I gave her, in addition to the gallic acid and ergot mixture, the following:

℞.—Liq. potass. cit. . . . f ℥j.
Spts. æth. nit. . . . f ℥ij.
Tr. aconitæ rad. . . . gtt. xv.
Syr. limonis . . . . f ℥iv.
Aqua . . . . . q. s. ad f℥ij.—M.
Sig. Teaspoonful every two hours.

Wednesday morning I found her somewhat better, though still having slight fever; pulse 124 per minute, and moderately weak in character. I did not detect any abnormal heart sounds. I removed the lint packing without further bleeding, and with much relief to the patient. I then ordered tincture of digitalis in three drop doses, every three hours, and also the following:

℞.—Quin. sulph. . . . . gr. viij.
Tr. ferri citro-chlorid. . . f ℥j.
Syr. tolu . . . . . f ℥j.
Aqua . . . . . f ℥vij.—M.
Sig. Teaspoonful every three hours.

Digitized by Google

Thursday I found the patient, to use her own language, well; evidently much better. Fever had entirely subsided, the heart's action remained abnormally rapid. The cervical glands were slightly enlarged, but no enlargement of the tonsils and apparently no inflammation of the fauces. Treatment was continued with the addition of more nourishing food, beef-tea, wine-whey, etc.

The child seemed so much better that I said it might come to my office the next morning instead of my going there. Later, in the same evening, she took a sudden change for the worse but I was not sent for until Friday morning. Now the patient was suffering from high fever, 104° F. in the axilla; pulse 134 per minute, compressible. The cervical glands much enlarged and very hard; the bowels had not been moved for twenty-four hours; the tonsils were but very slightly swollen; there were no patches in the throat. Thinking that possibly she was developing a malignant form of diphtheria, I at once put her on the calomel treatment until the bowels were moved, giving her three grains, repeated in two hours; and then two grains; the bowels were moved freely, and the calomel was stopped. I also gave suppositories of two and a half grains of quinine every two hours; also,

℞.—Liq. ammon. acet. . . . fʒj.
Spts. æth. nit. . . . . fʒij.
Syrupi . . . . . fʒiv.
Aqua . . . . . fʒij.—M.
Sig. Teaspoonful every two hours.

I continued the tincture of digitalis in five drop doses every three hours. I also applied hot flaxseed poultices to the enlarged glands, and at noon plenty of beef-tea and milk, but the child did not care for food and it was difficult to get her to take any nourishment. At midday I noticed for the first time, although I had carefully and frequently listened before, a systolic heart murmur. The temperature was but little affected during the night, and next morning (Saturday) at 7.30 A. M. I found it as high as ever, 104° F. in the axilla. Fearing that endocarditis had set in from the continuance of high fever and the heart murmur, I at once applied a mustard plaster to the pericardium, followed by a poultice, giving internally potassium iodide and ammonium carbonate, continuing the digitalis until noon, when I met Dr. J. M. Keating in consultation.

Physical signs showed, in addition to what has been mentioned, an enlargement of the spleen, yet there was no history of malaria. Dr. Keating did not think that endocarditis had set in, believing the murmur to be rather of a hæmic character, yet, as a stimulant to the heart, suggested the application of a blister; internally, very small doses of Basham's mixture every three hours, with the free use of alcohol, beef juice in small amount, etc. The temperature to be kept down to 102°, or lower, by means of the wet sheet. On examining a specimen of the urine which had just been passed, and the first that I had been able to obtain, I found it to be of sp. gr. 1016, of a light straw color, free from albumen and sugar. The child could not retain either medicine or beef juice. The nose again commenced to bleed, to prevent which I again plugged the nostrils. Soon large clots of coagulated milk were vomited, the result of having been given by half-cupfuls at a time, which was entirely contrary to my direction. Her stomach soon became settled, and she took brandy and crushed ice in small quantities. We wrapped her up in a wet sheet once, then poured cold water over her until the temperature came down to 101° in the axilla, which required about 35 minutes, she was then wrapped in a blanket. In two hours the temperature was again 104°. We again gave several of the wet packs during the afternoon and evening, and notwithstanding we were at the same time giving two and a half grains of quinine every hour by suppository, the same rise in temperature was observed after each. During the night she took her medicine regularly; alcohol and water and beef tea were also administered.

Sunday morning (the day of her death) I found her, to all appearance, bloodless; pulse rapid and small; respiration shallow and too frequent; temperature rising to 104° after the wet pack, as before. During Saturday night she had removed the packing from the nostrils, which allowed a slight oozing of blood, and, this having been swallowed, gave rise to vomiting of clotted blood; this continued, after the bleeding from the nose had been again checked, at intervals of ten to fifteen minutes, which gave rise to the belief that there was a slight hemorrhage into the stomach; these clots differing somewhat in form and color from those which I ascribed to the epistaxis. The heart became more rapid — 138 per minute—and the patient gradually sank. She died at 6.30 P. M. in great agony, giving two or three shrieks, which were quite loud, considering her weakened condition.

Dr. William Osler kindly examined for me a slide of blood, and reported as follows:

"*Red corpuscles* present no special alteration in size or shape. *Colorless corpuscles* greatly increased in number—fifty or sixty in each field of the No. 7 Hartneck. They present remarkable variations in size; many are small, not more than one-third the size of the longer forms; they resemble the smaller colorless cells which Virchow has noted to be present in cases of lymphatic leukæmia. Many of the cells have feeble, amœboid movements. *Nucleated red corpuscles* not observed. *Schultze's granule masses* (often abundant in leukæmia) scanty."

The relation of the increase in number of the colorless corpuscles above noted to the increase in size of the glands and cytogenetic tissue is, indeed, hard to solve. The increase in size and hyperplasia of the spleen in leukæmia and anæmia are histologically identical. We must remember that the view that colorless corpuscles change into red corpuscles is not fully established; hence, also, that it is not proven that the excess of colorless corpuscles is due to failure in the change to red ones. In such cases the prognosis, when the disease is detected at its incipiency, may be favorable under rigid treatment of fresh air and suitable diet, iron, quinine, and arsenic and salt bathing; but in marked cases that have existed for some time with advanced symptoms the result is fatal.

SUPPOSED FRACTURE OF THE CORACOID PROCESS OF SCAPULA.[1]

BY ROBERT W. JOHNSON, M.D.,
OF BALTIMORE.

MOST observers, not familiar with the anatomy of the soft parts, would, on looking over the angles and projections of the skeleton, undoubtedly select the two hook-like processes of the scapula as especially exposed to fracture. Did you press them further and let them select the more frangible of the two, the coracoid process would probably be chosen because of its independent projection, and because of a quasi-constriction immediately posterior to the elevated ridge which gives attachment to the trapezoid ligament, while the acromion, bolstered as it is, by its junction with the clavicle, would indicate a strength which experience shows is fallacious. Should an anatomist, pure and simple, next have to decide the question, basing his conclusions merely on what he has found on dissection, and unbiassed by any surgical facts, I doubt whether he would place the coracoid fractures in so improbable, and, as some have it, impossible light as surgical writers of the present day.

"Fractures of the coracoid process are remarkably rare. I have seen but one decided instance," says Mr. Thos. Bryant.[2]

"This fracture is exceedingly rare."[3]

"The coracoid process is but seldom broken, there not being more than ten or twelve unequivocal cases of this accident recorded."[4]

"The coracoid process,[5] says Mr. Lizars, is said to be broken off, but this I question very much."

"The acromion and the coracoid processes[6] are occasionally broken off, the latter very rarely."

Druitt, Gant, Holmes, and others bear the same testimony. What is the secret of its immunity?

The deltoid muscle acts as a buffer to outside violence. The clavicular portion of the pectoralis major covers the front. The clavicle arches over a portion of it as a protecting roof, and often sacrifices itself to shield the coracoid.

Again, its curved contour fits to a certain extent the convex head of the humerus, from which it is separated by an elastic bursa and ligaments. It is further braced by the coraco-clavicular, coraco-acromial, and coraco-humeral ligaments, the short head of the biceps, coraco-brachialis, and pectoralis minor muscles. But before all these protective agencies, the mobility of the scapula itself may rank with its power of falling back on the muscular cushions which surround it when hard pressed by external violence.

Whatever be the cause or causes of infrequency, the fact remains that the coracoid process is but seldom broken, and that mostly by some serious injury, which has imperilled parts much more important.

As will be seen by the accompanying table, where the complication or concomitant injuries are mentioned, we find dislocation and fracture of humerus, dislocation of outer end of clavicle, fracture of base of skull, glenoid cavity, etc., all marking the injury as a very grave one, and the force used as excessive. There is but one case from muscular action alone, No. 18. Falls appear to be the most common immediate cause, while, of course, the coracoid is not exempt from the constitutional bone frailties that occur in syphilis, pregnancy, rheumatism, etc. Sex or age does not affect materially, since our list gives instances from childhood to threescore years and ten. Allen (*Human Anat.*, Sec. ii. p. 171) says: "The coracoid process acts as a check to the inward movements of the head of the humerus, and unless the process be broken, subclavicular dislocation can scarcely occur." He further adds, in regard to its development: "This process is homologous with the coracoid bone of batrachian reptiles and birds. As seen in these animals, the coracoid bone extends between the sternum and scapula very much after the manner of the clavicle in the human subject."

The diagnosis of this fracture is not so simple as a casual observer might suppose, for on looking at the table we find that most of the cases have been discovered by post-mortem examination. The severity of the accompanying injury, the fact that but little displacement occurs from the action of the pectoralis minor and short head of biceps, unless the rare rupture of the coraco-clavicular ligament also happens, and the ready way in which injuries about the shoulder-joint swell, all mask the separation of the coracoid until the scalpel of the pathologist discloses it. Crepitus, pain, and mobility are more to be depended on in life, especially if all the other bony parts of the shoulder yield negative results on examination

In regard to treatment, there is not much to be said. This silence, however, is not due to the results of treatment being ineffectual, a condition of affairs that brings out either a host of specifics in the hands of charlatans, or a few suggestions from the pens of real thinkers, but because the application of one or two anatomical facts, together with the requisite amount of common-sense, will effect many cures.

Place the divided bones in position, and keep them there if possible. This is best done by relaxing the biceps and coraco-brachialis muscles, by semiflexing the forearm, and relieving the tension on the pectoralis minor, by laying the forearm across the chest. The ligaments, if not ruptured, will be serviceable splints. A Velpeau bandage will maintain the parts at rest.

The following case is reported because it is believed to be a fracture of the coracoid process—a diagnosis made after careful examination, but not stated positively because of the rarity of the lesion, together with the fortunate recovery of the patient.

Mr. K., æt. 76 years, fell, striking his right shoulder against a projecting board. When first seen by me, through the kindness of my friend, Prof. Miltenberger, I found evidence of shock, the right arm was powerless, the shoulder somewhat swollen, and a contusion one and a half inches below the acromion, and slightly to the posterior side of the humerus. Movement was very painful, and occa-

sional crepitus could be clearly felt when the arm was rotated. The head of the humerus was thrown a little forward and inward, but readily answered to all movements imparted at the elbow. Suspecting a fracture of the clavicle, and knowing the slight displacement occurring when the line of separation lies between the coracoid and trapezoid ligaments, I made a most careful examination of that bone, but found absolutely no crepitus nor any pain on pressure throughout its entire length. The acromion was intact, there was no break about the glenoid cavity. The head of the humerus responded to all movements of the shaft, and yet there was unmistakable bone crepitus; this, too, directly over the coracoid process, where the pain was most intense. One point I regret I omitted on account of the suffering that pressure over this process caused, and that was to examine as to the mobility of the coracoid. Had I done that and found it movable, the title of this paper would have been more definite.

A Velpeau bandage continued six weeks, followed by massage and the faradic current, were the means of restoring his arm to its former integrity. The coracoid process is now immovably fixed to the scapula.

64 FRANKLIN STREET, BALTIMORE, MD.

SOME USES OF COCAINE IN GYNECOLOGY.[1]

BY CHARLES HERMON THOMAS, M.D.,
FELLOW OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

SELDOM does a new drug reach so sure a place in the confidence of the medical profession as that accorded to cocaine. I very early began its employment in ophthalmic practice, and soon extended its use to a variety of gynecological applications. The results obtained have been so satisfactory that I now never go to such a case without cocaine in my bag or pocket. After considerable experience in its use, I am convinced that it is quite as valuable in the latter case as in the conditions for which it was originally recommended. That it is a local anæsthetic when applied to mucous surfaces especially, is a familiar fact; but its property of reducing inflammation and engorgement of the same class of tissues is not so generally recognized, notwithstanding that it is a point of considerable practical importance. This action of the drug is readily verified by observing the marked paleness and shrinkage which follow in a few moments after its application to surfaces thus affected. While this condensation of tissue is to a considerable degree temporary, it seems to be of longer duration than the accompanying anæsthesia. In some cases the good results obtained by reducing hyperæmia in this manner, appear to be permanent. The common fear that it will fail to prevent pain may usually be overcome by placing a few drops of the solution on the tip of the patient's tongue, when the numbness produced seldom fails to induce full confidence in its efficacy. Cocaine hydrochlorate is the salt upon which my experience is based.[2] A four per cent. solution (gr. ijss to fʒj) in water acts well for most purposes, though a somewhat weaker or stronger one may sometimes be substituted with advantage. The addition of boracic acid in the pr. portion of gr. ij to the fʒj insures sterility of the solution.

When used, it should be applied with thoroughness, the parts being first freed from mucus, and some minutes allowed to elapse for its effects to develop; the time should be not less than two minutes, and in cases where considerable pain is to be anticipated, a strong solution, ten per cent. or more, may be employed, and the application repeated after an interval of two minutes, and in five minutes from the beginning the full effects of the drug may be looked for. That the anæsthesia produced by cocaine is complete, I have personally experienced, having made use of a four per cent. solution by injection into the nostrils previous to an application of the galvanic cautery to the nasal cavity. The cautery had been applied on a previous occasion without cocaine, and the pain was severe. With it, not the slightest pain was felt once, and I was conscious of the action of the cautery only by the hissing sound produced.

I have found it particularly valuable in certain cases of cervical endometritis in which, though there may be no erosion externally, and but little characteristic discharge, there is a state of extreme sensitiveness existing about the region of the internal os uteri, a probe or cotton easily bringing blood, and any application made to the part is liable to produce bleeding and severe radiating and ovarian pain. Cocaine carefully applied with the syringe or cotton-carrier, prevents the pain and bleeding, which would otherwise follow the necessary medicinal application. The swelling is thus also materially reduced, and the congestive or inflammatory stenosis which usually exists, is consequently for the time relieved, and applications to the part itself as well as to the entire endometrium, are greatly facilitated.

In urethral caruncle sensibility may be so destroyed, that the painful excrescences may be clipped off, and the site painlessly cauterized. Cocaine is also extremely useful in painful irritation and inflammation of the female urethral tract, and especially of the part just within the meatus; a condition attended with distress frequently referred to the bladder. Appropriate medication is painlessly made after its application, which may be conveniently made by means of the glass medicine dropper. As a means of preparation for the operation of stretching either the urethra or the cervix uteri, it is of unquestionable value.

To precede the application of caustic to chancre, it is also effective. I am informed by my friend Dr. Levis, who uses it extensively, and with great satisfaction, that in plastic operations upon the vagina where considerable surfaces are to be flayed, the cocaine anæsthesia is insufficient to prevent pain. It has been recommended in dysmenorrhœa, and there is good reason to believe from several reports which have been made, that it is capable of producing excellent results when applied to the os uteri, and to the cervical cavity, by means of a small cotton tampon. I tested it recently in a case of uterine colic, using it

[1] Read before the Obstetrical Society of Philadelphia, November 5, 1885.

[2] The price has recently been reduced to ten cents a grain or less.

Digitized by Google

hypodermically, in two doses of one grain each, about half an hour apart, but without appreciable relief.

It has been tried internally, in doses of one grain or more in the vomiting of pregnancy, and has met with some favor, but in the only case within my own knowledge, it entirely failed.

In a case of painful vaginismus brought me by a practitioner from a neighboring city, the condition was quickly relieved by the local application of cocaine, and a complete examination was easily made, where, without its use, general anæsthesia would have been necessary. In a case of hyperæsthesia of the vagina with mild vaginismus, in which frequent local treatment was required, a suppository containing one grain of cocaine, introduced into the vagina a half hour before each treatment, entirely abolished the spasm, and rendered the introduction of the speculum easy and comparatively painless. Cocaine suppositories also produced excellent results in a case of rectal tenesmus, after opium had proved inefficient.

Cocaine has been recommended in operations for lacerated cervix, and for the crushing of stone in the bladder. I have not made use of it in either of these applications, but strongly believe in its value.

In one hyperæsthetic patient, in whom violent pain was developed on slight provocation, and who required local treatment of the cervix uteri and urethra, but who suffered so much from ordinary applications, that the local benefit was fully counterbalanced by the harm done nervously, it became necessary, on this account, to suspend treatment. After cessation for six months, treatment was resumed under cocaine, and it has since been in every way satisfactory, the pain formerly produced by applications to the cervix now being entirely absent. In the same patient painful irritability, with spasm of the bladder simulating cystitis, which was not entirely relieved by the opium suppository and other measures, yielded completely, and thus far permanently to a single injection of one grain of cocaine thrown into the bladder. The resumption of treatment in this instance was largely due to the enthusiastic approval of the husband, who had himself experienced complete relief from the injection of a drachm of the two per cent. solution into the deep urethra, for a violent urethrismus. In another instance, in a woman with irritable pile, red as a ripe strawberry, and who was suffering extreme discomfort, the pile shrank and turned pale under the cocaine application, and was then painted with tincture of iodine, with entire absence of pain.

MEDICAL PROGRESS.

TOXIC EFFECTS AFTER THE LOCAL USE OF COCAINE.—Experience in the use of cocaine as a local anæsthetic is beginning to prove the necessity of some degree of caution as to the quantity used, as several cases in which symptoms of cocaine poisoning have occurred have been up to the present time reported by various observers widely separated from one another. KNAPP described headache, vertigo, nausea, tottering gait, pallor of the skin, and cold sweat as the result of daily hypodermic injections of thirty-five drops of a four per cent. solution, with instillation of a few drops of the same solution in the conjunctival sac. G. MAYERHAUSEN, of Freiburg, after applying fifteen drops in two drop doses, at intervals of from five to eight minutes, to the eye of a little girl of twelve in whom the lachrymal secretion was so copious that he felt sure that half the application was lost, or that the total quantity of cocaine which was capable of producing any effect was probably not more than 0.005 gramme, found headache occur immediately after the operation, which was followed by irritation in throat and great nausea, with some temporary paralysis of the tongue, from which unpleasant effects she did not recover for twenty-four hours. PECK, on using cocaine on a lady on whom he performed tenotomy, observed a marked paleness come over her face.

REICH recently reported two cases in the *Russkaya Meditsina* in which similar toxic symptoms occurred, the one being a girl of ten years of age, the other a woman of sixty. In both cases a two per cent. solution was employed, and the quantity used did not in either exceed fifteen drops. STEVENS mentions a case in which faintness and cold perspiration were observed, but which he thinks were perhaps due to nervousness, as on a subsequent occasion this patient suffered no ill-effects from cocaine. He had, however, another case where seven or eight minims of a four per cent. solution produced spasm and loss of consciousness in a healthy male subject.

Quite recently an account has been published by Dr. BELLYARMINOFF, of St. Petersburg, of five cases in which the use of a four per cent. solution in various eye operations was followed by headache, vertigo, nausea, vomiting, delay in the healing of the corneal wound, and in some instances by traumatic keratitis. All the patients were elderly females, in a more or less emaciated condition. It was found that ice and morphia were ineffectual in arresting vomiting, and that the best treatment was wine. In some of the patients a subsequent operation was well borne by using a two per cent. solution and limiting the number of drops instilled. Dr. BELLYARMINOFF remarks that when cocaine is badly borne the patient is generally a female, and aged, or badly nourished. He thinks it safer to use a two per cent. than a four per cent. solution. Finally, it must be added that cocaine has been charged by KEYSER, of Philadelphia, with causing a tendency to panophthalmitis after cataract operations, he having found this serious complication occur in three cases out of seven in which he used the drug.—*The Lancet*, November 7, 1885.

THE REGENERATION OF BONE SUBSEQUENT TO TREPANATION.—V. MARTIN, after a study of the results of others and by his own experimental investigation, reaches the following conclusions relative to the regeneration of bone subsequent to the operation of trephining:

1. In young animals the newly formed osseous tissue takes its origin both from the medullary cavity limited by the circumference of the trephined bone, under the form of osseous centripetal tracts, and from the external surface of the dura mater under the form of osseous nuclei, which tend to unite with the former.

Digitized by Google

In old animals, a thinning of the bony margin occurs, from loss of substance, which is found full of dense and fibrous tissue.

2. The pericranium does not contribute, or only to an extent not appreciable, to the reparation of the bone.

3. The vitality and the consequent complete adhesion of osseous disks introduced and placed in position, is assured at all times when suppuration does not ensue, and this when moderate may not prevent a partial growth, of greater or less extent.—*Rivista Internazionale di Medicine e Chirurgia*, October, 1885.

DECOCTION OF LEMON IN THE TREATMENT OF GONORRHŒA.—MANNINO, in the *Annales de Syphiligraphie*, recommends the decoction of lemon in the treatment of gonorrhœa, holding it to be the best parasiticide of the gonococcus. His observations are conclusive, though not numerous. The remedy may be applied during the acute stage and but a very few days elapse until the condition begins to improve.

The decoction should be prepared with three good lemons, neither too green, nor over-ripe, cut in small pieces and put in about ten ounces of water, contained in an earthen vessel. Gentle heat should be applied until one-third of the quantity remains, the solid portion rejected, and the remainder used for injection.

The number of injections should be from three to four daily and only a fresh preparation used, a new decoction being made every two days.—*Revue Médicale*, October 24, 1885.

CASE OF ULCERATIVE ENDOCARDITIS WITH EMBOLISM IN THE MOTOR PORTION OF THE LEFT INTERNAL CAPSULE.—E. PERZICCHETTI (*Gazzetta degli Ospitali*, No. 51, 1885) records the case of a patient who for twenty years had been a sufferer from intermittent fever. Becoming suddenly ill with fever and chill, for two days he was unable to work. Shortly afterward he was again attacked with fever, and going to a hospital, he was placed under treatment for malaria. The spleen was much enlarged, owing to the duration of the disease, and in a few days, his condition in the meanwhile failing to improve, complete motor and sensory paralysis of the right arm and leg supervened. The heart was found hypertrophied and an aortic diastolic murmur easily recognized, from all of which diagnosis of ulcerative endocarditis with cerebral embolism was made.

Death occurred in a few days, and post-mortem examination made by Prof. Marchiafava, revealed the presence of a focus of softening, the size of a bean in the posterior portion of the left internal capsule and the neighboring portion of the optic thalamus. The arteries of the brain were normal and permeable.

The left leaflet of the aortic valves was found covered with soft granulations and fibrinous clots, and the spleen and right kidney contained hemorrhagic infarcts.

Dr. Perzicchetti considers it remarkable that the embolism did not occur in the arteria fossæ Sylvii, or in the arteria lenticolo-optica.—*Centralblatt für klin. Medicine*, October 24, 1885.

PERIOSTEUM GRAFTING.—DR. C. M. TRUEHEART reports a case of reproduction of two and three-fourths inches of the clavicle in the human subject, by grafting with periosteum and with thin laminæ of bone, covered by its periosteum taken from a dog. The patient on whom the grafting was performed was a young man aged twenty-two, who had had about three and a half inches of the central portion of the clavicle shot away, together with an extensive mass of the adjacent soft tissues.

Measures taken to secure early union were ineffectual, and when, after six or seven weeks, examination revealed no prospect of union, either osseous or ligamentous, it was decided to resort to periosteal grafting. As a preliminary step, all new tissue in the tract of the injury was removed by the scissors and fuming nitric acid, and an excavation thus made three-fourths of an inch deep, about an inch wide, and two and three-fourths inches between the nearest projection of the end of the fractured bone.

The fragments of the clavicle were maintained in position by the axillary pad, etc., and healthy granulation having been obtained, small pieces of periosteum, the size of a large flaxseed, were placed upon the ends of the bones and into the wound, which was shortly covered with perforated oil-silk, covered with a compress of picked lint, moistened in a two per cent. carbolic solution. On the fifth day, seven or eight of the grafts were found to be taking.

In the course of a month three successive graftings were made, cicatrization of the edges of the wound being in the meanwhile retarded by cauterization.

Two months after the grafting the entire gap, which had existed in the clavicle, was filled up with a tissue possessing the characteristics of bone as to hardness, inflexibility, and perfect performance of function of giving support to the heretofore dropping shoulder, there being no appreciable difference in the length of the two clavicles.

At the present time the bone remains the same, with the exception of some contraction in its transverse diameter, and an irregularity caused by the angular union of a fracture, the result of a severe fall occurring some months ago.—*The Medical Record*, Oct. 3, 1885.

TRICHLORACETIC ACID: A NEW DISINFECTANT.—FILIPPOREITCH, of Odessa, adds another to the long list of antiseptics. The substance is known as trichloracetic acid, and, according to its introducer, is an active antiseptic, even in a two per cent. solution. In a strength of from one to two per cent. it destroys all organic life; in weaker solutions of from one to one-half per cent., it does not hinder the development of ferments, or of mould, but arrests that of bacteria—micrococci. According to Filipporeitch, the rank of trichloracetic acid among the disinfectants is the third place, corrosive sublimate and carbolic acid alone being superior to it, while chloride of zinc, boracic acid, and potassium permanganate are inferior to it.

Trichloracetic acid is a crystalline substance, easily soluble in water or alcohol, of pleasant odor, and coagulates albumen freely.

In concentrated solution it is caustic. Diluted it provokes hypersecretion of the saliva, and destroys completely its power as a salivary ferment.

As a therapeutic agent, it is an excellent remedy in

Digitized by Google

erysipelas, in cutaneous excoriations which appear as a result of œdema in the lower extremities, in renal and cardiac disease, and in syphilitic ulcers, for the treatment of which it is not inferior to iodoform.

As a lotion, it is useful also in muguet.—*Gazzetta degli Ospitali*, October 25, 1885.

THE OCCURRENCE OF ABNORMAL QUANTITIES OF FREE HYDROCHLORIC ACID IN GASTRIC CRISES OF A TABETIC, WITH REFERENCE TO THE QUESTION OF NERVOUS INFLUENCE UPON THE SECRETION OF THE GASTRIC JUICE.—SAHLI (*Correspondenzblatt für Schweizerische Aerzte*, 1885) records some interesting observations on the case of a tabetic, which make it probable that the secretion of the physiological gastric juice, similar to the cardialgic pains occurring as a result of pathological changes in the spinal cord, are directly due to spinal influences, and are not of reflex peripheral origin.

He found in the vomit of a tabetic with severe gastric crises, a quantity of hydrochloric acid much above normal, and the same condition persisted even if the patient remained twelve hours entirely without food. The gastric crises then became so severe that almost constant vomiting existed, and examination showed the matter vomited to consist of pure gastric juice with a slight admixture of salivary secretion.

The stomach, under ordinary conditions, produces no acid except during digestion, and the phenomena here noted allow no other conclusion to be drawn than that the hypersecretion of the gastric juice is to be attributed directly to pathological changes in the spinal cord.—*Deutsche med. Wochenschrift*, October 15, 1885.

THERAPEUTIC VALUE OF THALLIN AND ANTIPYRIN.—The powerlessness of antipyretic agents to modify the actual course of continued fevers or to shorten their mean duration is, we believe, admitted by the large majority of clinical physicians. M. Jaccoud has communicated to the Académie de Médecine the results of a clinical investigation into the antithermic effects of thallin and antipyrin. The medicament has been administered by him in a systematic manner to reduce the pyrexia of typhoid fever, tuberculosis, and pneumonia. It is asserted that no other substance, given in such small doses, produces so marked an effect on the temperature as thallin. The nature of the disease appears to exert some influence on the duration of the antipyretic effect, which was most prolonged in cases of tuberculosis. Hardly, however, does the thermometer reach its lowest register before the temperature begins to rise again. When the temperature begins to fall copious sweats commence, and are the more abundant as the descent of temperature is more pronounced. The perspiration ceases when the temperature begins to rise. Thallin should be cautiously administered, since there is sometimes much danger of collapse setting in. Occasionally the administration of thallin, as with antipyrin, is attended with the appearance of a cutaneous eruption. As a rule, the eruption takes the form of papulous erythemata, which are at first minute, but gradually acquire larger dimensions. This erythema usually commences to appear on the internal aspects of the knees, and spreads afterwards on the extensor surfaces of the limb. So far as is at present known, the rash has not been noticed on the face. The average duration of the eruption is three days, but it may last two days longer. This complication is much more frequent with antipyrin than thallin. As the result of his clinical investigations, M. Jaccoud finds that thallin is a far more powerful antipyretic than antipyrin, but he asks the pertinent question whether it is useful to employ these medicaments. It appears that both prevent the axillary temperature from reaching its usual height for a certain time, but neither has any certain influence over the central temperature of the body, which remains at its usual height, even if it be not augmented. The peripheral cooling does not benefit or relieve the distress of the patient, but rather weakens him. The effects, indeed, are of an illusory nature. M. Jaccoud finishes by saying that these agents cannot be regarded as constituting real aquisitions to medical therapeutics.—*The Lancet*, November 7, 1885.

HYDATID TUMOR OF THE THYROID BODY.—DR. MEINERT, of Dresden, reports the case of a girl aged fourteen, in whom a swelling of the thyroid body for the last few months had occasioned great difficulty in breathing, during labor or in ascending steps.

The remaining members of the family were healthy, and no goitre had ever existed in them. When about four years of age, when convalescent from typhoid fever, the neck of the patient had been lanced for abscess of the parotid (?), and the tumor first made its appearance a few days after. Until eight years of age, the swelling increased uniformly, continuing to grow until it reached its present size, that of a large orange, and situated almost in the median line.

On account of absence of fluctuation, the growth was at first considered to be scrofulous. Treatment with injections of alcohol was first resorted to, and the slight resistance to the introduction of the needle at once attracted attention.

Exploratory puncture gave exit to a thin watery fluid, absolutely colorless, a result which was entirely unexpected, having never been confirmed in previous operations upon strumous conditions of the gland.

Consultation being held, incision was recommended, and being made, a pure white cyst rushed from the wound *in toto*. No scolices or daughter cysts, however, were found. A drain was introduced, and in three weeks the wound was healed.

The origin of the cyst is supposed to be traceable to the presence of a family dog, which was the constant playmate of the child, the tænia having been introduced into the wound made to relieve the abscess, occurring subsequent to the attack of typhoid fever.

The case is probably the first recorded instance of hydatid tumor of the thyroid body.—*Centralblatt für Chirurgie*, 1885, No. 24.

A CASE OF DISLOCATION OF THE FIRST CERVICAL VERTEBRA; RECOVERY.—DR. R. H. CARTER reports the case of a sailor who fell from the rigging of his vessel, a distance of about twenty-five feet, striking the back of his neck or head on a rope eight or ten feet above water. When he struck the water he had a slight convulsion and lay motionless. Examination showed the occiput

Digitized by Google

drawn well back and down as far as possible, the chin projecting forward but not raised.

Pressure in the furrow behind the occiput was unendurable, producing great pain and a general tetanic condition.

The symptoms resembled those of strychnia poisoning, save that the face was unaffected. The left arm was blue, cold, sweating profusely, rigid, and absolutely powerless. The right arm was powerless, but less rigid than the left.

The legs were not paralyzed but rigid and clumsy. Sensibility was at first present, but later was lost, and the patient was unable to swallow even his saliva.

Every attempt to bring the head forward produced unconsciousness, during which he was flaccid; on recovery, there was a succession of spasms, the extensor muscles being very rigid.

The finger being introduced into the pharynx forward, displacement of a vertebra was discovered at its upper border, and diagnosis of displacement of the first cervical vertebra on the second was made.

A full dose of chloral having been administered by enema, the head was strongly lifted and slightly extended and rocked, by an assistant, while Dr. Carter made pressure with his thumb upon the projection of the pharynx. After manipulation lasting from one to two minutes, the projection yielded and the head came into position. The patient was able to swallow immediately and within two days the general symptoms resulting from the fall had disappeared, except the vasomotor derangement in the left arm, which in a measure was persistent sixteen days after the accident. — *The Medical Record*, September 5, 1885.

ARTHRITIS OF THE OSSICULA OF THE EARS; THE USE OF IODIZED FUMIGATIONS IN VARIOUS AUDITORY AFFECTIONS. — M. NOEL GUÉNEAU DE MUSSY, in the last volume of his clinical lectures, devotes some time to the study of a form of deafness produced by arthritis of the auditory ossicles. Such deafness is peculiar in the fact that under excitation and shock to the ear, it diminishes. Thus the noise of a carriage, locomotive, or a very sharp sound, may momentarily reëstablish the sense of hearing in those persons who ordinarily hear almost nothing.

The form of this affection which accompanies gout, has a great tendency to become chronic, and cause complete loss of hearing. Care, however, enables the affection to be treated with a certain degree of success, and every auditory congestion and cold should be avoided.

At the end of a few days from the beginning of the symptoms, resort should be had to iodine fumigation by placing in the meatus a plug of iodized cotton enveloped in wadding, care being taken that the thickest portion of the plug corresponds to the opening of the external ear.

At the end of from 24 to 36 hours the plug should be renewed.

The same process may be adopted in the treatment of parenchymatous metritis, or other affections where the use of iodine is desirable. In the last-named affection, M. de Mussy has obtained notable decrease of the uterine engorgement.

In women disposed to hemorrhage the remedy is contraindicated, as favoring its occurrence. — *L'Abeille Médicale*, October 26, 1885.

PARALYSIS OF THE RECURRENT LARYNGEAL NERVE IN CHRONIC LUNG DISEASE. — BÄUMLER, in the *Deutsche Archiv für klin. Medicin*, Bd. xxxvii. Hft. 3 und 4, reports some observations in which paralysis of the recurrent laryngeal nerve occurred, as a result of a chronic inflammatory condition of the lungs occasioned by inhalation of dust, and attended with extensive formation of new tissue.

In these cases there was chronic indurative neuritis of this nerve, which was the result either of chronically inflamed bronchial glands in its neighborhood, or of inflammation derived from the nutrient bloodvessels.

In the first case, that of a miller, aged 61 years, in whom the cause of hoarseness was recognized by the laryngoscope to be a left sided recurrent paralysis, post-mortem examination showed slaty induration of the apices of both lungs, and overgrowth of the left recurrent laryngeal beyond the point at which it turns round the aorta, by a very firm, densely pigmented bronchial gland.

In a second case, post-mortem examination revealed the presence of callous induration, and bronchiectatic cavities in the apices of both lungs, together with true cirrhosis of the left recurrent nerve at its point of origin from the vagus. In this case there was present an easily recognized arteritis obliterans in the vessels in the territory of the diseased nerve. — *Centralblatt für klin. Med.*, October 17, 1885.

THE TREATMENT OF RACHITIS BY PHOSPHORUS. — GRIEBSCH, *Jahrbuch für Kinderheilkunde*, 1885, Bd. xxiii. Hft. 1 und 2, reports forty-one cases of rachitis treated with phosphorus according to the prescription of Kassowitz, *i. e.*, in the form of an emulsion, and in most instances with accompanying salt baths.

In four cases cure resulted after the use of from one-sixth to two-thirds of a grain of phosphorus. In eleven cases the improvement was marked, in eight insignificant, in twelve nil, and in six the condition became worse.

Of the special manifestations of the disease, the following is noted:

Cranial rachitis occurred in forty-one cases. In seventeen, no change was noted; in nineteen, improvement; in one, the condition in a short time was aggravated.

In rachitis of the ribs and lower extremities, the treatment was without result.

Kyphosis existed in ten cases, and was benefited in three instances, continued in six, and grew worse in one. The weakness of the lower extremities, as well as the general debility, was uninfluenced in seventeen cases, while in the remainder the results were such as, in the opinion of the author, might easily have been accomplished by other treatment.

In view of the results obtained, Dr. Griebsch concludes that phosphorus is of but small value in the treatment of rachitis, and cannot be considered as a specific, and even questions whether, as a remedy, it is

Digitized by Google

sufficiently safe to be used without caution.—*Centralblatt für klin. Medicin*, October 17, 1885.

HABITUAL ABORTION DUE TO RENAL DISEASE OF THE MOTHER.—DR. FEHLING of Stuttgart, calls attention to the fact hitherto unrecognized, that renal disease in the mother may give rise to habitual abortion, and cites the history of several cases in proof of the correctness of his view.

The first case related was that of a woman who aborted six times in succession. Each time, about the fifth or sixth month of pregnancy, œdema of the entire body ensued, and albumen was abundant in the urine, miscarriage occurred about eight weeks subsequent to the symptoms of the death of the fœtus. All the placentæ were small and atrophied and the decidua thickened. Syphilitic remedies were prescribed in vain by the family physician.

In a second case, about the middle of pregnancy, symptoms of the death of the fœtus occurred, concomitantly with the presence of an abundance of albumen in the urine. This diminished under treatment, but abortion occurred nevertheless, the fœtus being mummified. After the accident the albumen disappeared from the urine. A third and fouth case, likewise recorded, exhibited similar symptoms, abortion occurring in each, and in one instance the nephritis being first recognized by the ophthalmoscope.

Fehling's observation is interesting, as being the first to recognize renal disease as a causal agency in the production of abortion.—*Centralblatt für Gynäkologie*, October 10, 1885.

EXPERIMENTS ON THE VITALITY OF THE BACILLUS OF PHTHISIS.—PROFESSOR G. SORMANI and DR. E. BRUGNATELLI, of Pavia, have recently instituted a great variety of carefully conducted experiments to determine the action of various chemical reagents on the vitality of the bacillus of tubercle. These experiments are embodied in a pamphlet lately published, entitled "Ricerche Sperimentali sui Neutralizzanti del Bacillo Tubercolare."

The sputa of undoubtedly phthisical cases were mixed with certain medicaments, thirty-six in number. A portion of each mixture was injected either into the subcutaneous cellular tissue or into the peritoneal cavity of numerous guinea-pigs. The effects were carefully noted, and the animals subjected to a rigorous post-mortem examination. Of the medicaments used, the following were found to exert a strong neutralizing effect—in fact, in most cases the animals retained their full health, no trace of tubercular deposit being discovered on examination after they had been killed. The neutralizing power of the medicaments was found to stand in the following order, beginning with the least active: Lactic acid, camphoric acid (a saturated solution), camphor (a saturated alcoholic solution), bromide of ethyl, naphthol β, turpentine, chloride of palladium, creasote, naphthol α, phenic acid, and bichloride of mercury. Professor Sormani is still continuing his experiments, and one in particular he has made at the suggestion of Dr. Hassall. The sputa were dried at a low temperature, and were then mixed with olive oil, which was allowed to be in contact with the powder for some time until it had become well saturated with the oil. This experiment was undertaken in the belief that the vitality of the bacillus would be impaired by the exosmotic action set up by contact with the oil. Dr. Sormani writes as the result of the experiment: "I find an action of attenuation in which the bacillus by preference is multiplied in the lymphatic glands, and not in the viscera."—*The Lancet*, November 7, 1885.

THE VESICATING PROPERTIES OF METHYL IODIDE.—DR. ROBERT KIRK, in discussing the merits of methyl iodide as a vesicating agent, concludes as follows:

From the preceding statement it will be observed that the iodides of both ethyl and methyl are more powerful agents than the strong tincture of iodine already mentioned, and which Dr. Churchill considered the best of all applications to the cervix uteri. As distinguished from most other agents which are applied to the cervix or the interior of the uterus, iodine is characterized by its tendency to produce a serous instead of a plastic exudation, but in this respect it is much surpassed by its methyl and ethyl compounds. These circumstances point to the two latter bodies as peculiarly applicable where such effects of iodine are deemed desirable; and I have found the application of methyl iodide to the cervix have a remarkable effect in relieving pain in some forms of uterine disease. For milder effects and for application to the interior of the uterus the ethyl compound is an excellent agent. The effect of this body applied on a Playfair's probe to the fundus, and retained there one minute, is often remarkable. A few days afterwards the cervix has generally the soft feel and even the somewhat purplish tinge of the cervix of pregnancy. The cervical canal will frequently admit a sound which could not previously be passed; while pain is almost invariably relieved.—*The Lancet*, October 24, 1885.

NEW LOCAL TREATMENT OF ECZEMA AND OTHER CUTANEOUS DISEASES.—DR. GÉCÉ has recently made trial of the local treatment of eczema by ichthyol applied by means of a thin dressing of some sufficiently strong, but pliable substance, acting as an artificial epiderm, and at the same time combining medicinal treatment with the advantage of being able to be applied by the patient.

The dressing adheres without the use of a bandage, and is applied by simply moistening with warm water, and needs only to be renewed every three or four days.

In acute eczema and chronic eczema, especially that of the lower limbs, where the application affords methodical compression, and in prurigo and lichen, the first application has given favorable results. In psoriasis the results have been encouraging, but further experience is necessary to determine the real value of the remedy.

To apply the dressing, it should be permitted to rest for an instant upon warm water of a temperature which can be supported by the hand, and smoothly applied.

If any difficulty is experienced in removing the dressing, a corner should be raised and moisture applied by wetting both sides, when it will be found to come away easily.—*L'Union Médicale*, October 31, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, NOVEMBER 21, 1885.

RESECTION OF THE JAW FOR ANCHYLOSIS.

IT is a very remarkable thing to find an operation, which would seem to be so natural as this, among the most recent and rarest in the history of surgery. And yet, so far as available statistics indicate, resection of the lower jaw, at the joint, for anchylosis, has been done only in about thirteen cases, and of these only three have been in this country. The first operation was performed, in 1874, by Dr. S. D. Gross, and the other two were done, in 1875 and 1884, by DR. J. EWING MEARS. The first of Dr. Mears's operations is reported in the *Transactions of the American Surgical Association* vol. i., and from a short historical sketch of the subject, which is appended, it may be seen that a number of surgeons have come quite near the idea of this operation. One of the earliest was Dr. Carnochan, of New York, who, in 1840, suggested the removal of a segment of the lower jaw in order to restore its mobility; while independently, although fifteen years later, Esmarch proposed a similar operation, which is now known by his name; and, in 1857, Rizzoli divided the jaw in front of a cicatricial contraction, and inserted gutta-percha plates to prevent subsequent union of the divided surfaces. None of these operations, however, is to be classed with resection of the jaw at the joint, a procedure which should properly be credited to Bottini, who, in 1872, communicated to the Royal Academy of Medicine of Turin a case in which he did a subperiosteal resection of both condyles for permanent closure of the jaw. He was the first to operate directly upon the joint, and the result was most excellent.

In 1874, the elder Gross, in a case of complete synostosis of the lower jaw of the left side, in a girl seven years of age, excised the condyle along with a portion of the neck of the bone, through a curvilinear incision in front of the ear, and established excellent motion. König, in 1876, did a resection of the left temporo-maxillary articulation for anchylosis, and he operated in the same way again in 1877. Both cases were entirely successful. His method of operating is as follows: An incision, about an inch long, is made over the lower border of the zygomatic process, and another, about two-thirds of an inch long, is made perpendicular to, and descending from the former. The latter incision is carried only through the skin, so as to avoid the facial nerve. Through this opening, after cutting some of the fibres of insertion of the masseter muscle, the articular process of the maxilla is cleared with a raspatory, after which it is carefully separated from the ramus with a chisel, and removed from the cotyloid cavity. König reported these cases in the *Deutsche Zeitschrift f. Chirurgie* in 1878, and recommended removing the coronoid process also when this might be necessary. At about the same time, and apparently independently of any suggestions, von Schultén operated upon both sides of the jaw, commencing with the removal of the coronoid processes. König's method has been followed, with slight modifications, once by Ranke in 1878, and twice in 1885; once by Hagedorn, in 1880; and once by Langenbeck, in the same year; while Kulenkampf reports an operation in the *Centralblatt f. Chirurgie* of this year as done by the method of Mears.

When to this list is added another operation by König, in which the patient died of chloroform narcosis, we have a concise history of the operation of resection of the lower jaw, at the joint, for immobility. In analyzing the cases reported, and more particularly the interesting paper upon this subject by Mears, already referred to, and a recent one by RANKE, in the *Archiv f. Chirurgie*, Bd. xxxii. Heft 3. 1885, we observe that the operation is not so clearly defined as to its indications, or its mode of performance as one might at first sight suppose. As now understood, it may be described as an exsection of the articular process of the inferior maxilla for anchylosis, with subsequent freeing of any adhesions, cicatricial, muscular, ligamentous, or bony, which stand in the way of its success. But it is clear that the operation of excision of this part of the bone is wholly out of place as a means for the restoration of motion which is impeded solely by contraction of the soft tissues. For this, other measures may be successfully employed. The operation cannot, moreover, be considered as strictly applicable to the cure of irreducible luxations, although it has been twice done successfully for this object. For its legitimate purpose, however,

Digitized by Google

there can be no question that it is deserving of a high place in the list of approved surgical measures. In the perfection and permanency of its results it leaves little to be desired. The old methods of wedging and prying open the jaw were harsh and comparatively fruitless. This is painless to the patient, and almost absolutely safe, if properly carried out.

But what is the best method of doing the operation? To this question we think it is safe to answer as Ranke does, namely: to make the first incision of König over the lower border of the zygomatic process, and to omit his second, perpendicular to it. When it comes to the separation and removal of the piece of bone, we would strongly urge the advantages of drilling it out with the rapidly revolving burr of the so-called "dental engine" invented by Dr. Bonwill, of this city. When this machine is used by one who understands its management, its work is vastly superior to anything which can be done by the chisel and mallet, even in the most accomplished hands. As it is, unfortunately, not always available, the next best method is to use the chisel as carefully as possible. In some of the operations reported, the bone forceps, or the saw, has been used. But these have all been cases in which there was much more than a simple exsection of the articular process. That of Dr. Mears was a removal of quite half of the ramus. Peculiar circumstances, such as there existed, may demand the resection of so much bone, but in its simplest form the operation should not contemplate this.

Before closing, it may be well to refer to a proposition made by Bassini, of Milan, in 1879, to correct anchylosis of the jaw, by removing, with a small trephine, a portion of the neck of the bone. This method has much to commend it where it is feasible, but it differs only in degree from the earlier operations in which the bone was divided at different points below the seat of the adhesions. Ranke thinks it is open to the objection applicable to all of them, namely, the liability to speedy reunion. That may be, or not, as experience may decide. At any rate, the operation of excision at the joint, with which the names of Bottini, Gross, König, and Mears are justly to be associated, is one which may be commended to further trial on the part of surgeons who have to deal with otherwise incorrigible anchylosis of the jaw.

CHOREA.

THE etiological and pathological relations of chorea are still obscure, and widely divergent opinions prevail on many questions connected with the disease. A much debated point is the association of it with rheumatism, the percentage of cases connected with this disease ranging in the tables of different authors from two or three to twenty-five or thirty. It is certainly true that a considerable number of all choreic patients have joint pains, which are usually attributed to rheumatism, but JOFFROY and his pupil, SARIC, in *L'Union Médicale*, Sept. 22, regard them as choreal arthropathies associated with the nervous affections, and not necessarily of rheumatic origin.

In support of this view they refer to the absence of fever, the fugitive character of the pains, the small number of joints affected, often of one side only, and the absence of heat, or swelling. The cardiac troubles they attribute chiefly to functional disturbance. They regard the disease as a cerebro-spinal neurosis associated with the evolution of the nervous system, and, in the female particularly, with the development of puberty. The influence of psychical causes—fright, emotion, imitation—in causing the disease, the intellectual disturbance, the predominance of the trouble on one side, and the character of the motor and sensory affections without any constant pathological lesion, point, they think, to a neurosis. That the spinal cord is also affected is shown by the abolition, or diminution of the reflexes in twelve of sixteen cases, and by the arthropathies which may be considered as trophic lesions of the joints.

Joffroy's views of chorea as a neurosis of growth are not new, but the suggestion of the relation of the joint affections to the cerebro-spinal trouble is worthy the attention of those interested. With reference to the participation of the spinal cord in chorea, we may refer to the interesting observations of Dr. Money on the experimental production of the disease in animals. By injecting a particulate liquid into the carotid, he has produced involuntary movements indistinguishable from those of chorea, and this was found to be associated always with embolism of the capillaries of the cord. The movements induced were both irregular, as seen in the chorea of man, and rhythmical repetitions of one movement as in the ordinary chorea of dogs.

DR. H. C. WOOD has recently given a statement of his views on this subject, and adduced further evidence in favor of the participation of the cord in the disease. In two choreic dogs, after section of the cord, the movements still continued, as had been demonstrated by Chauveau, and this experiment proves conclusively that, in these animals at least, the movements originate in the cord. But further, in four cords from cases of canine chorea, there were found, in three, mild grades of infiltration of leucocytes in the gray matter, and in the fourth, in which the animal had died of the disease, the ganglion cells were degenerated, and in some places had disappeared altogether. He concludes that choreic movements may depend upon a diseased condition of the motor cells of the cord, a condition, in most in-

Digitized by Google

stances, not sufficiently marked to be noticed with our instruments, but in others it may go on to produce changes in the ganglion cells, or even their total destruction. There are at least five or six cases of human chorea in which there have been observed distinct lesions of the spinal ganglionic cells, and in some instances embolism of the antero-lateral arteries of the cord, as recorded by Ross. But, as Kirkes originally suggested, and as the investigations of Jackson, Broadbent, Bastian, and others have shown, there are other instances in which capillary embolism about the basal ganglia seems to stand in causal connection with the phenomena of the disease. Neither the cerebral nor spinal changes, however, are constant, as cases have been examined in which no definite lesions could be determined.

Many of the clinical features of chorea are quite inexplicable on the embolic theory—as the production by fright, or imitation, the influence of season, as pointed out by Mitchell, the rapid cure by arsenic, and its occurrence in epidemic form, as happened repeatedly during the middle ages, and in the early part of this century in Tennessee and Kentucky, as reported by Robertson in 1805. We must suppose, therefore, the disease to be produced by a variety of causes. Dr. Wood defines the chorea of childhood, as "a diseased condition of the ganglionic structures of the cerebro-spinal axis, which abnormal state may exist without alterations of structure sufficient to be determined by the microscope, or may go on until it is accompanied by marked structural lesions. Further, this condition must be looked upon as one of lowered tone, and it must be allowed that it may be produced by various causes." An important point has always been duly insisted upon by Hughlings-Jackson, namely, that we must suppose in chorea over-activity of some nerve elements to account for the coexisting over-movement. It is absurd to suppose that from cells in a state of advanced degeneration, shrivelled and wasted, motor impulses, active though irregular, could proceed. Such destruction could account for paralysis, but surely not for over-movement. Hence it can scarcely be a condition of lowered tone.

In spite of the occurrence of choreic movements under various conditions, and the multiple origin of the disease of childhood, we may still look upon chorea as a distinct nosological entity. Dr. Wood does not regard it as such, holding that the word should be employed "as analogous to, or having equal rank with, paralysis or tremor;" but after excluding the cases of post-hemiplegic, of rhythmic (hysterical), and of electric chorea, there remains the affection of childhood with its well-marked characters, which is as much deserving of recognition as a separate disease, as is epilepsy, or tetanus.

ELECTRICITY IN OBSTETRICS AND DISEASES OF WOMEN.

SEVERAL interesting contributions relating to the uses of electricity in obstetrics, and in diseases of women, have recently appeared. Among these, may be mentioned the application of this agent in the cure of extrauterine fœtation, by DR. LANDIS, in *The American Journal of the Medical Sciences*, for October, papers presented by BAYER and LOEWENTHAL to the Gynecological Section of the German Society of Naturalists and Physicians, which appear in the *Centralblatt für Gynäkologie*, October 17th, a paper by APOSTOLI and DOLÉRIS, upon the treatment of periuterine hæmatocele by galvano-puncture, published in the *Archives de Tocologies*, November, and a paper upon electricity as a therapeutic agent in gynecology, read before the New York Academy of Medicine by DR. MUNDÉ, which appeared in THE MEDICAL NEWS of last week.

From experiments upon insects, minnows, and rabbits, Dr. Landis has been led to conclude that the faradic current in extrauterine pregnancy should be applied for an hour, if the patient can bear it so long; it should be applied repeatedly, and it should for at least one sitting be used in great strength.

Bayer reported four cases in which the constant current was used for the induction of premature labor. The first was a 5-para, who in her four previous labors had been delivered of dead children by podalic version. At the end of nine lunar months the constant current was used, and after the first application labor pains were excited, while after the sixth the mouth of the uterus was completely dilated: a living child was born, but it survived only ten days. In the second patient pains were also promptly excited by the constant current, and she gave birth to a living child which died in six hours. In the third the os uteri was dilated after seven applications, but the pains always ceased after the interruption of the current. At the expiration of three weeks and a half spontaneous labor occurred at the normal time, and a living child was born. In the fourth patient, after nine applications, a gangrenous ulceration of the cervix appeared; when this healed the application was renewed, with at least a partially satisfactory result.

Bayer concludes that the constant current excites uterine contractions, dilates the os, and removes cervical stricture. He very justly remarks, after referring to the fact that the results are not the same in all cases, that a brilliant effect is only had when the uterine musculature is very good, and the neck is not very rigid.

In the discussion of the paper, Homburger stated that he had failed to increase the labor activity in a primipara by this means, but that in two cases of

Digitized by Google

uterine fibroids attended with metrorrhagia, in which ergot had been used without benefit, the constant current gave an excellent result. Schatz regarded it as very probable that the uterus, like the heart, had nerves, which not only strengthened the activity of contraction, but also some which weakened it; and that the nearer the subject is to the end of pregnancy, the more quickly and certainly various means for the induction of labor act. Müller, in one case, had a very satisfactory result in the induction of labor by the constant current, while in five others, on the contrary, it failed.

It is evident, from this discussion, that we cannot accept the use of the galvanic current as a certain means of inducing labor.

Loewenthal, in a series of cases of chronic metritis, used at first faradization, then the mixed currents: the effect, especially of the latter, was prompt and lasting, so that uteri, the cavities of which measured five inches, were reduced until they measured only about three inches. The other cases in which electricity was used successfully were those of genital neuroses.

As to the method of application, Loewenthal always places the cathode in the uterus, and the anode upon the abdominal wall; the current should at first be weak, the strength gradually increased, and again made weaker before withdrawal. Thus the application is painless, but the effect is greater and more lasting if the current be suddenly interrupted. The electrode should not be placed in contact with the anterior vaginal vault, because severe pain is thereby produced. The sitting should be only from five to ten minutes, and ought never be continued more than fifteen minutes. He found no benefit from the continuous current. He regards electricity as of no value in the treatment of positional disorders of the uterus, except in relieving the nervous symptoms which may be connected with them, and he considers the mixed currents as only indicated in the treatment of chronic metritis and genital neuroses.

Loewenthal's denial of the value of electricity in positional disorders of the uterus is too positive, as one may see by referring to Tripier's *Leçons Clinique sur la Maladies des Femmes*, Paris, 1883. Several cases of uterine deviations—both versions and flexions—are there narrated, which were cured by faradization. The results obtained by Tripier have been in part confirmed by experiments made in the dispensary department for diseases of women in the Jefferson Medical College Hospital. These were conducted by Dr. Graydon, and in some cases uterine flexions were cured by this means, the instrument and electrodes advised by Tripier being used, and his method strictly followed. An objection to the treatment of uterine deviations by electricity is the long period required—in some instances six months, and hence the difficulty in securing the regular and continued attendance of patients.

Apostoli and Doléris report a case of retrouterine hæmatocele occurring in a woman forty years of age, which was opened nearly six weeks after its appearance, by negative galvano-puncture through the vagina. The positive pole is put in connection with a cake of clay upon the abdomen, or upon one of the thighs; the force of the current should reach one hundred milliampères, and usually the application is continued five to ten minutes; the cauterization should penetrate from about four-tenths to eight-tenths of an inch. Should the puncture open a large vessel, and serious hemorrhage follow, the arrest of this is at once made by forced dilatation of the vagina by means of Gemrig's speculum, which is kept in place for some time.

We fail to see in the history of this case any advantage from this method of opening the hæmatocele, which could not have been attained, had this been done by the thermo-cautery, or the galvano-cautery knife. It is claimed, however, by the author, that the method used, not only secures a large fistulous outlet, but also creates in the blood-mass an intimate process of disintegration, followed by a rapid regression.

A very full abstract of Dr Mundé's paper having been so recently given in THE NEWS, it is unnecessary to repeat this in even a condensed form. Our belief is, that the author does scant justice to the intrauterine galvanic pessary, and that he asserts too positively that the instrument owes its value to its being a foreign body: this last statement may be true, but any one who has observed the rapid corrosion of the zinc portion of the pessary, will not regard it as impossible that some galvanic action is developed while it is in the uterus. Our experience authorizes us to assert that a faithful trial of this instrument properly applied, and in suitable cases, has been followed by results that we believe could not have been otherwise obtained.

Dr. Mundé's paper, however, is a most valuable and timely contribution to the subject of electricity in diseases of women.

SOCIETY PROCEEDINGS.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, November 5, 1885.

THE PRESIDENT, B. F. BAER, M.D., IN THE CHAIR.

LYMPHATIC LEUKÆMIA IN CHILDHOOD.

DR. JOHN M. KEATING read a paper on this subject, which is particularly interesting on account of its clinical rarity and the infrequency with which we meet the disease in current literature. He prefaced it with a few

Digitized by Google

remarks on the blood in children in health, and also spoke briefly upon its condition in disease.

(See page 562.)

DR. GOODELL inquired whether there are any distinguishing points between purpura hemorrhagica and lymphatic leukæmia. If there is a deficiency of red blood-corpuscles, why do red patches occur so easily?

DR. KEATING remarked that the subject under discussion was dependent upon certain conditions which physiologists are still debating. In leukæmia we have, as a diagnostic feature, an involvement of the lymphatic system more or less, a hyperplasia of the tonsils, lymphatic glands of the peritoneum and of the intestines, also of the spleen and bone-marrow, all of them being more or less connected with red-cell formation, but the principal diagnostic point is the increase in number of the colorless cells, as is noted in Dr. Osler's report. The hemorrhages in these cases are possibly due to a diapedesis or capillary rupture. In what is known as purpura hemorrhagica there is an exudation of blood cells, or the hematin from their destruction into the rete mucosum and the papillary layer of the cutis; of course, capillary ruptures may occur with profuse hemorrhage. The blood cells (red) are usually diseased, they become crenated or they cease to form rouleaux, and possibly the plasma may be at fault. The microscope alone will reveal the distinguishing features. Purpura may be considered a symptom accompanying a dyscrasia in which the blood itself is involved, not merely the organs of its production.

DR. WILLIAM GOODELL exhibited the ovaries from two cases of oöphorectomy with the following histories:

OÖPHORECTOMY FOR OVARALGIA.

When the patient, an unmarried woman aged thirty, first consulted him, she weighed two hundred and thirty-six pounds, but at the same time she was very weak and could barely walk. She suffered excessive pain at her catamenial periods, which appeared only at long intervals. She had cataleptic and hystero-epileptic fits, and complained of very constant and acute ovarian pains. Her urine was passed but once a day and this act was attended with much suffering. The womb was enlarged and the ovaries were very tender indeed, but nothing else abnormal was discovered. Asafetida and the bromides were prescribed in large doses, and she was advised to try the rest treatment.

Fourteen months later she was again brought by her physician to consult Dr. Goodell. She now weighed only one hundred and twenty pounds, having lost one hundred and sixteen pounds, and she was in every respect worse, her ovarian pains being now constant and acute, requiring large doses of morphia to control them. Her catamenia had not appeared for nigh four months, and tonics seemed to have no effect whatever on her. Her physician was compelled to be in constant attendance and was liable to be summoned at any hour, day or night, to give her a hypodermatic injection. Masturbation was suspected, but she always denied the practice. Nothing further could be done than the operation of oöphorectomy, which was accordingly performed a few days later at the hospital of the University. The ovaries were found much enlarged from cystic and interstitial degeneration, but there were no evidences of peritonitis or of cellulitis, which had been suspected. A corpus luteum existed in one ovary, a rectal hemorrhage or vicarious menstruation having taken place a few days before the operation. Her ovarian pains at once left her; she needed but very few doses of opium, which were given by rectal suppositories. Her convalescence was prompt and she returned home in less than four weeks free from all pain, and in a fair way to get perfectly well. The case was a typical one of the advantages of oöphorectomy, yet he thought that the operation is being performed altogether too frequently.

OÖPHORECTOMY FOR BLEEDING FIBROID OF THE WOMB.

In this case the lady was thirty-seven years of age, and had been married eleven years. She gave birth to a child about seven years ago, and since then has had one premature birth at seven months and one miscarriage. She first noticed an abdominal tumor nine years ago, but her catamenia began to be free some time before this. Late in the year 1881 the catamenia began to be excessive. As nothing served to check them, early in the following year Dr. Goodell was consulted. He found multiple fibroids of the womb. Six tumors could be readily made out, of which two seemed pedunculated; the sound gave a measurement of 4.5 inches. Under ergot and ammonium chloride the patient improved for several months; then the menorrhagia became worse, and finally a dribbling of blood kept up between the periods. In May of the present year she again consulted Dr. Goodell. She had been dribbling continuously since January, and was much reduced in strength. Being a brunette, she exhibited the facies uterina in a marked degree, the pigmentation being very dark and extensive. The womb now measured 7.5 inches. She was admitted into Dr. Goodell's private hospital, and on May 24 both ovaries were, without difficulty, removed. They were greatly enlarged by follicular degeneration, a condition which Dr. Goodell had repeatedly seen in cases of fibroid tumor. The effect of the operation on the tumors, and especially on the main one, was astonishing. After two weeks this fibroid had diminished in length nearly a hand's breadth. Her recovery was prompt, and she was sent to Atlantic City to recruit. On July 10, just forty-seven days after the operation, she called on Dr. Goodell, who found the tumors very greatly reduced in size, and the uterine cavity measuring only 3.25 inches, a diminution of 4.25 inches.

This extraordinary amount of diminution, in spite of the fact that the obliteration of the ovarian bloodvessels cut off only a small portion of the blood-supply to the womb, drove him to the conclusion that the ovaries were the important factors in inviting blood to the womb. Every successful case in which he had removed the ovaries for fibroid tumor of the womb had been followed by the menopause and by rapid diminution in the size of the tumor. But in his hands, and in those of others, this operation was more fatal than that of ovariotomy. During the ten months of the present year he had had twenty-five cases of ovariotomy, with but one death, and that one in a lady operated on at her home, two hundred miles from Philadelphia. For simple cases of oöphorectomy the mortality should not be greater than that of ovariotomy. But when complicated with the presence of a large or an adherent fibroid

Digitized by Google

tumor, the operation is often one of great difficulty. Twice during the past year he was unable to reach the ovaries, and was compelled to abandon the operation, because in neither case was the woman willing to undergo the risk of having hysterectomy performed. Each case recovered; and while the women were under observation the tumors appreciably lessened in size, as if the shock of the exploratory incision had temporarily suspended the ovarian influence.

DR. MONTGOMERY was glad to hear the good results of Dr. Goodell's cases. In a few of the cases upon which he had operated, the menopause did not at once occur, sometimes not for two years after the operation. In such cases the tumor did not decrease in size while menstruation continued. In the case of hysterectomy for fibroid tumors, reported by Dr. Montgomery at the last meeting, the temperature at no time exceeded 101⅘°, and the patient left the hospital to-day perfectly well. He preferred removal of the uterus and its appendages entire when the ovaries cannot be removed in consequence of previous inflammatory changes. Ligation of bloodvessels supplying the tumor might be useful when nothing better could be done.

DR. BAER thought that when the ovaries can be removed, it is the perferable operation.

DR. GOODELL has been so uniformly successful in removing the ovaries for the cure of fibroid uterine tumors that it is his choice. He has been notified that in a case of fibroid tumor of the womb in a woman aged thirty-two years, he will be called in consultation; this will be the third. He will advise removal of the ovaries; if at the time of operation that is not found possible, he will close the incision, as the other operation is very dangerous, and the patient can certainly live a few years as she is. In one case only of his oöphorectomies has the menses continued, and he thinks that in that case these must have been some supplementary ovarian tissue.

OVARIOTOMY.

DR. MONTGOMERY exhibited for Dr. Warden a large ovarian tumor, and related the following history: The patient was a young woman. Her menses commenced at seventeen years of age, and had always been irregular. They ceased entirely for twelve months, and at the same time the abdomen was enlarging until the tumor reached above the navel. Fluctuation was doubtful; the mass seemed quite solid, and pressed the uterus down into the pelvis. Anæsthesia did not relax the abdominal wall, and diagnosis was doubtful. An exploratory incision, showing the pearly tint of an ovarian tumor, made it sure. Nothing would pass through the trocar but some of the jelly-like contents of the tumor escaped beside it, and passed into the abdomen. The large cyst was filled with small cysts. The patient did well for one week, when the pulse became rapid; but she has since been doing well, and is now rapidly recovering.

DR. GOODELL thought the danger from the escape into the abdomen of cyst contents is overrated.

DR. BAER said that in the early stage of ovarian tumors metrorrhagia is sometimes present; sometimes the menses are entirely absent. He should like to hear from the Society some reason for this inexplicable difference.

DR. GOODELL has observed the same fact, but can throw no light upon it.

DR. MONTGOMERY remarked, that in this case both ovaries had undergone cystic degeneration. The second ovary contained numerous small cysts.

DR. BAER inquired about the treatment of the second ovary.

DR. MONTGOMERY replied that it was removed.

DR. CHARLES HERMON THOMAS read a paper on.

SOME USES OF COCAINE IN GYNECOLOGY.

(See page 567.)

DR. KEATING has used cocaine for some time in the same class of cases. He now uses eight per cent. solution with great success, especially in children's throats. He employs salicylate of cocaine in diphtheria in a five or six per cent. solution; sensibility disappears in a short time, and he can then use any application without discomfort, he applies carbolic acid, tincture of iodine, etc., in this manner without exciting pain. He also applies cocaine before injecting carbolic acid into piles, and also applies it on cotton to prevent its action from ceasing too soon.

DR. THOMAS said that the strength of the solution may, with propriety, be greatly varied, and that in his practice upon the eyes even a one per cent. solution is strong enough to be of considerable value in conditions of irritation produced by foreign bodies in the eye; but in other cases, as urethral caruncle, it may be well to use it even in saturated solution. The question of strength is largely a question of expense, for in local application no toxic results are likely to be produced.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, October 27, 1885.

THE PRESIDENT, ROBERT F. WEIR, M.D., IN THE CHAIR.

STRICTURE OF THE ŒSOPHAGUS; INTERNAL ŒSOPHAGOTOMY.

DR. H. B. SANDS presented a woman, twenty-one years of age, who had come under his observation one year ago last June. She was sent by Dr. Paddock, of Dalton, Mass., on account of a stricture of the œsophagus, which was the result of the accidental swallowing of a solution of caustic potash when she was two years old. Dr. Paddock stated that he had been called to see the patient on account of dysphagia. She was unable to swallow solid food, and was badly nourished. He detected a close stricture through which he could pass only the smallest sized bougie. When she came to Dr. Sands he was able to confirm the diagnosis made by Dr. Paddock, and found a stricture situated seven inches from the incisor teeth, through which he could introduce a French catheter, No. 12. He endeavored to dilate the stricture, and succeeded in carrying the dilatation up to No. 23, French, but was unable to accomplish more. Therefore, on the ninth of July, 1884, he introduced the œsophagotome, which he had already shown to the Society, passed the bulb beyond the stricture, projected the blade one-tenth of an inch and then withdrew it, making an incision in the posterior median line of the œsophagus. Immediately after the opera-

Digitized by Google

tion, which was performed without an anæsthetic, and was attended by no hemorrhage, he passed a No. 29 French bougie; subsequently he carried the dilatation up to No. 34, French. After the cutting operation instruments were at first passed every second or third day, and during the summer and autumn at intervals of three weeks. In December the interval between the introduction of the bougies was increased to one month, after the first of January to two months, and now there has been an interval of three months without any diminution in the calibre of the œsophagus at the point where it was divided.

Soon after the operation, exploration of the œsophagus revealed the presence of another stricture ten inches from the incisor teeth, which admitted No. 24, French. Dr. Sands dilated this stricture, and carried the dilatation up to No. 29; but beyond this he had been unable to dilate it.

He then demonstrated the lower stricture, and showed that the upper stricture allowed a bougie, No. 34, to pass, while the lower one arrested instruments larger than No. 29.

The reason why he presented the patient was because he thought it desirable to correct the common impression that all strictures of the œsophagus exhibit an invincible tendency to recontraction, and that the operation of internal division is unsatisfactory because it is not likely to produce any permanently good result.

It so happened that he had received this evening a communication from the friends of a child upon whom he had performed several operations of internal œsophagotomy two years ago for the relief of a stricture of the œsophagus, and whose case he had already reported to the Society. In that instance the dilatation was carried up to No. 29. The child improved in health, is able to eat solid food, and has remained well ever since. At the present time she swallows as other children do, yet no bougie has been passed since last May.

Dr. Sands cited these facts in order to prove that internal œsophagotomy may sometimes produce results which are permanent; and although the œsophagus may not be restored to its normal dimensions, it may not show a tendency to contract below such dimensions as will permit easy deglutition.

He had been led to desist from doing more in the case exhibited this evening because the patient is in good health, has gained in weight from ninety-six to one hundred and nine pounds; is able to swallow liquids without difficulty, and with care to swallow solids when well masticated.

Stricture of the œsophagus closely resembles strictures of the urethra, in which there is found every grade of constriction, and also a vast difference in the amount of tissue which causes it. He had seen a case of stricture of the œsophagus in which the entire tube was converted into a rigid canal. Under those circumstances no operation whatever could succeed in restoring a fair amount of dilatability of the œsophagus; but he believed that in many cases strictures are limited to a very short part of the canal, and in those cases he imagined that the operation of internal œsophagotomy would be likely to be followed by the greatest relief, with a minimum amount of risk.

DR. STIMSON asked, Why refrain from further operation upon the lower stricture in the patient presented?

DR. SANDS replied, only because it seemed already large enough to allow the easy deglutition of masticated food, and also because it had not shown any tendency to contract below the calibre of No. 29. He was, moreover, inclined to refrain from cutting the lower stricture for the reason that it is related to more important parts than the upper one; therefore accident in the operation may be more serious in its results. He imagined that the calibre of the œsophagus may be restored to its normal size, but he did not feel warranted in doing more than seems absolutely necessary to render deglutition easy.

DR. W. T. BULL had had occasion to treat one case, that of a lady who entered the New York Hospital two years ago. The stricture was about ten inches from the incisor teeth, and depended, so far as they were able to determine, upon a bad sore throat, possibly diphtheria. The patient could swallow only with great difficulty anything except water. The stricture admitted only No. 8, possibly No. 10, French. By persistent gradual dilatation the stricture was stretched until at the end of four months it admitted No. 32 or No. 34, French. Dr. Bull saw the patient up to one year afterwards. The bougie was passed at short intervals during four months, and at intervals of one month during the remainder of the year, at the end of which time the condition of the œsophagus was perfectly satisfactory, as she could eat anything which she chose.

CONGENITAL ANGIOMA.

DR. MCBURNEY presented a man who had a congenital angioma of unusual size upon the right side. The tumor was five inches in breadth, four in depth, and extended from the median line in front to within three inches of the median line behind. The patient stated, that during early youth and until within the last seven or eight years the tumor had bled regularly, and that he had lost large quantities of blood, sometimes as much as a quart at a time. During the last seven or eight years he has been very comfortable with firm compression of the growth, and has had no hemorrhages. Dr. McBurney felt inclined to advise him to continue with this treatment, and not to have any operation whatever performed. The tumor was not pulsating at any part, was venous, and was of the cutaneous and subcutaneous variety, chiefly the latter.

EPITHELIOMA OF THE TONGUE; REMOVED BY KOCHER'S METHOD.

DR. L. A. STIMSON presented a specimen of epithelioma of the tongue, for which he had removed almost the entire organ by Kocher's lateral supra-hyoid method. The patient was a man 68 years old; the disease extended as far back as the finger could reach through the mouth, and involved the floor of the mouth and the gum on the right side from the median line two inches backward. On the dorsum of the tongue was a very large irregular ulcer. Tracheotomy was done and the etherization was continued through the tube. The incision was made on the right side, and the right lingual and facial arteries tied in the wound before division; the left lingual was tied through the wound after divi-

Digitized by Google

sion, and this is the only ligature that was made necessary by the removal of the tongue. The entire organ, except a strip of mucous membrane at its base, was removed, as was also a portion of the submental muscles which had become involved in the disease. The area of raw surface created by the removal, was diminished by drawing the adjoining mucous membrane over it so far as possible and stitching it fast. The wound was packed with iodoform gauze, the mouth frequently cleaned by washing with a solution of salicylic acid and borax, and the patient has been regularly fed through an œsophageal tube. The tracheotomy tube was removed on the sixth day. The patient is now (16th day) doing well.

DR. SANDS had within the last ten days had occasion to remove the lateral half of the tongue on account of a cancerous swelling situated on the left side of the organ, extending toward the root but not to the median line. He adopted the method known as Whitehead's method. He etherized the patient, introduced Wood's mouth gag, passed a stout ligature through the tongue upon the right side, drew it forward, divided with a pair of straight scissors the attachment to the lower jaw and to the floor of the mouth, split the tongue in the median line toward the root, then made a transverse cut, dividing the tongue and the anterior pillar of the soft palate, and completed the operation with loss of only about eight ounces of blood. He had but little difficulty in applying a ligature to the lingual artery. He packed the wound with gauze, and used a small stomach tube for feeding the patient; during the first week the progress of the case had been entirely satisfactory, and the man is now able to swallow, and is convalescent. Dr. Sands was very much impressed with the excellence of the method in those cases in which the disease is strictly limited to the tongue. He was sure that the operation could be safely done if the entire organ required to be removed, and he should prefer to perform this operation rather than that which included a preliminary ligation of one or both lingual arteries.

DR. BRIDDON asked whether the difficulty in securing the arteries would not be greater in Whitehead's operation.

DR. SANDS replied that the operation did not consist in cutting off the tongue at once, but by making short strokes, and tying the arteries as they are divided. Of course, the cases should be selected in which the operation is especially applicable.

THE PRESIDENT remarked, with regard to Kocher's operation for removal of the tongue well back, that it had pleased him most on account of the thoroughness with which all diseased tissue can be removed.

NECROSIS OF THE HUMERUS WITHOUT THE FORMATION OF INVOLUCRUM.

DR. A. C. POST presented a specimen of necrosis of the humerus without any attempt at the formation of involucrum. It was removed from the arm of a boy 12 years of age, with the history that, between one and two years ago, he was bitten by a spider, and that the bite was followed by very severe inflammation. A number of months afterward extensive suppuration occurred about the joint, and Dr. Post performed excision of the elbow. Subsequently he found the wound at the joint had healed, but that there was suppuration higher up and loss of continuity in the bone of the arm nearly as high as the middle of the humerus. Recently he cut down upon the bone and found that its lower extremity was necrosed to the extent of 2¾ inches on one side and 1⅝ inches on the other. The dead bone was lying loose in the midst of granulations. The inferior extremity of the living bone above presented a jagged extremity, but was not bone to any considerable extent. He did not remember any other instance in which necrosis of a long bone of an extremity had occurred without the formation of involucrum, except in a case of necrosis of the fibula; also in a boy, in which the tibia was not involved. In that case the fibula for its whole length, except the two articular extremities, was in a state of necrosis, and there was no involucrum. The tibia formed a support for the limb, so that there was no false point of motion.

DR. L. A. STIMSON thought that something besides simple necrosis had occurred in the bone presented, and it was filled with bony deposit, and that the shell had disappeared by absorption.

DR. POST remarked that the whole process is different from the ordinary process of necrosis, but the bone was evidently dead.

MONTREAL MEDICO-CHIRURGICAL SOCIETY.

Stated Meeting, November 6, 1885.

THE PRESIDENT, THOMAS G. RODDICK, M.D., IN THE CHAIR.

TUMORS OF THE OVARY.

DR. WM. GARDNER presented two ovarian tumors which he had removed from the same individual; the right one had been removed by enucleation of the cyst, and the left by ligature of a very broad pedicle. Troublesome hemorrhage occurred, which was with difficulty arrested by ligature and the thermo-cautery. The patient did well.

DR. TRENHOLME also presented a large ovarian tumor which he had that day removed, and which, on the right side, contained a large solid mass, which he looked upon as malignant.

FATAL PULMONARY EMBOLISM ARISING FROM SIMPLE FEMORAL THROMBOSIS.

DR. GEORGE ROSS exhibited the heart and lungs of a patient, under his care, who had died suddenly in the General Hospital. The pulmonary artery, on being laid open, showed its left branch plugged by a thick fibrinous clot, beginning an inch above the valves, the lower end lying loose in the main artery, and for some distance curled back upon itself. Still nearer the heart, and almost touching the valves, lay a second loose clot, about three-quarters of an inch long, having the same appearance as the first. The clotting extended far into the lung, and even some of the small bronchial branches were plugged. The right pulmonary artery and its divisions were quite similarly occupied by an extensive fibrinous deposit. The femoral vein was also shown, containing a clot several inches in length, and extending a long way down the internal saphenous vein.

The patient was a young woman who had presented the usual symptoms of a simple anæmia for some months, when she developed pain and swelling of the

Digitized by Google

right leg. She was then admitted to the Montreal General Hospital, under Dr. Ross, when the existence of a femoral thrombosis was readily detected by the presence of a firm cord in the situation of the vessels. Her general condition was good, with the exception of a moderate degree of anæmia. One week after admission, after having passed a good night, she complained early in the morning of suddenly feeing faint; this soon passed off, and nothing more was thought of it. At 12.45 P.M she became suddenly breathless and much distressed. Stimulants were administered, but in fifteen minutes she was dead. The occurrence of pulmonary embolism was immediately suspected, and at the post-mortem the condition already described was found.

Dr. Ross remarked that, although very frequently meeting with femoral thrombosis, it was the first time he had ever observed this fatal accident following from it. It had been his misfortune a short time since to meet with a sudden death ten days after a natural confinement, and a perfectly natural puerperium. An autopsy in this case likewise showed the fatal result to have occurred from pulmonary embolism, as had been suggested. The present case was of interest from the syncopal attack in the early morning, which no doubt was produced by surprise of the heart at the arrival of a foreign body. Dr. Ross said he had been very much struck in both these cases by the great extent of the clotting through the branches of the pulmonary artery, which must have taken time to form, although no pulmonary symptoms prevailed during that period.

EXCISION OF THE SPLEEN.

THE PRESIDENT (Dr. Roddick) exhibited portions of a spleen which he had removed a few days ago from a man in the General Hospital. The man had been struck by a loaded bucket of coal whilst in the hold of a vessel. The bucket, containing about half a ton of coal, had fallen from a height and crushed him against the side of the ship. When brought to hospital he was suffering severely from shock, greatly blanched and almost pulseless. There was a small wound in the left lumbar region between the last rib and crest of the ilium, which was bleeding freely. There was also fracture of several of the lower ribs on left side. Dr. Roddick enlarged the wound and found that he came immediately on the intestines, the intervening muscular structures being all torn away, leaving nothing but skin covering the intestines. Through this wound he removed a mass of tissue, which, on examination, proved to be a portion of spleen; the wound was enlarged still further, and the hemorrhage was found to come from a ruptured spleen. The vessels entering the hilus were ligatured, and the spleen was without difficulty taken away.

The man only survived the operation about six hours. At the post-mortem the lower six ribs on left side were found fractured, the left kidney lacerated in several places, and the bladder full of blood. There were only a few ounces of blood in the abdominal cavity.

GUNSHOT WOUNDS OF THE TESTICLE.

DR. JAMES BELL read a paper on gunshot wounds of the testicle, and reported two cases which he had seen in the late Northwest rebellion.

The first case was that a young soldier, aged twenty-eight, who, whilst skirmishing before Batoche, was struck by a rifle-bullet on the outer side of thigh immediately below and behind the great trochanter. On being brought to the field hospital it was discovered that the bullet had passed through the thigh, then entered the perineum at the root of the scrotum, and made its exit through the scrotum, carrying away a portion of the testicle. The portion of testicle that remained was extruded from the lacerated scrotum. After removing several pieces of cloth in the track of the bullet, the parts were cleansed with weak carbolic lotion, the injured testicle was returned to its proper place, and tbe scrotal wound closed with catgut sutures. There was no hemorrhage or other troublesome symptom, and the wounds were dressed with iodoform and carbolized gauze. The patient was now sent by steamer to the base hospital at Saskatoon. On his arrival (some days after the injury) he was found to be suffering from urinary infiltration, due no doubt to sloughing of the tissues and the perineum, injured by the bullet. Extensive sloughing occurred, and his life hung in the balance for days, but the scrotal wound never reopened, although most of the left side of the scrotum sloughed away. When last seen, July 1st, his wounds had all healed; the right testicle was about half its original size, firm, free from pain and tenderness, and freely movable in the scrotum. It had apparently quite recovered from the severe wound received two months previously.

The second case was that of a half-breed, æt. 32, who was found on the battlefield of Batoche, on the night of the 12th of May, severely wounded. He was brought to the field hospital for treatment, and was found to be suffering from a contused and lacerated wound, about two inches in diameter, on the back and outer part of left thigh just below the great trochanter. The adductor longus muscle was torn and partially separated at its origin. The left testicle and the whole lower two-thirds of the scrotum were carried away. The right testicle hung down uncovered, and its lower half was filled with fragments of metal. The wounds were probably caused by the bursting of a shell. The wounds were washed and dressed, and the pieces of metal removed from the testicle. In a few days the lower half of the right testicle sloughed off, leaving an irregular granulating surface. The other wounds did well, and after a few days Dr. Bell dissected back the remaining portion of the scrotum, pared the edges, and brought them together over the testicle. The result was very satisfactory, for in a few weeks the scrotum was completely healed, and the remaining portion of the right testicle could be felt firm and painless within it.

Dr. Bell went on to say that the success attending the expectant treatment in these two cases inclined him to the belief that hardly any laceration of the testicle could be so severe as to warrant castration, although from what he had been able to gather from the literature of the subject within his reach, immediate removal of the organ was recommended in severe injuries. All authors say that the injured testicle usually atrophies, and is sometimes the seat of neuralgic pain, so that as far as future usefulness went it might as well be removed at once.

The patients, however, are always pleased to have as much saved as possible. In the statistics in the surgical volume of *The History of the American Rebellion* the

Digitized by Google

expectant treatment seems to have given better results than active operative interference; 586 cases are reported. The testicle was extirpated in 61 of these; 18 per cent. died. Of the remainder, treated by the expectant treatment, 11.9 per cent. died.

SEPARATION OF THE FIRST AND SECOND PIECES OF THE STERNUM.

DR. BLACKADER reported a case of a young man, aged eighteen, who, whilst exercising on the parallel bars in a gymnasium, felt something give away. On examination it was found that the first piece of the sternum was riding on the second; it was reduced without much difficulty, and kept in place with compresses and straps.

FRACTURE OF THE CLAVICLE WITH WOUND OF THE LUNG.

DR. F. W. CAMPBELL reported a case of fracture of the clavicle, in a coachman, aged thirty, caused by falling off his carriage and striking his shoulder on the wheel as he fell. The outer fragment was driven backward, and the lung was evidently wounded, as there was a large amount of air in the cellular tissue. The man when first seen was in a collapsed condition, and the whole neck was emphysematous. At first he was in doubt as to whether or not there was a fracture of the first rib, so he was sent to the General Hospital.

DR. RODDICK remarked that wound of the lung is a rare complication of fracture of the clavicle, and that there are very few cases on record. The man had been under his care in the hospital, and it was with difficulty that he could get the outer fragment into position. But the man is now doing well, and the bones are in good position.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, November 12, 1885.

THE PRESIDENT, J. C. WILSON, M.D., IN THE CHAIR.

DR. FORMAD presented specimens and read a paper entitled

AN ANALYSIS OF TWO HUNDRED AND FIFTY AUTOPSIES ON DRUNKARDS, ILLUSTRATING THE MOST PROMINENT ANATOMICAL LESIONS OF CHRONIC ALCOHOLISM.

He considered the most conspicuous lesions to be cyanotic induration of the kidneys, fatty infiltration of the liver, and mammillated stomach. His cases had been those, in which there was a history of a long-continued series of debauches, the subjects often dying in one of these debauches, and did not include moderate drinkers, or those who perished after imbibition of an enormous quantity of alcohol without any previous chronic excesses. He thought that the exposure, irregularities of diet, etc., incident to a state of drunkenness, had much—probably more than the alcohol itself—to do with the production of the lesions, but it is not at all possible to separate one from the other. He gave a long list of lesions considered by various authors to be results of chronic alcoholism, among which the cirrhotic liver with contraction held a prominent place. He had himself, at one time, considered cirrhosis a very frequent, if not almost necessary concomitant of long-continued excessive use of alcohol, and had even testified in court, that a certain person was not likely to have been a hard drinker, because at the autopsy no cirrhosis of the liver was found. He had thought, too, that the connection between the two is so close that it is impossible to have a case of cirrhosis, without a previous history of alcoholism, as is held by various authors. Therefore, it was surprising to him to meet in his two hundred and fifty autopsies, with only six cases of cirrhosis of the liver with contraction. In two hundred and twenty cases the liver was considerably, or even very much enlarged, the enlargement in most cases proving to be due to a fatty infiltration. Cyanotic induration of the kidney and chronic gastritis, with mammillation of the stomach, were found in nearly every case. This cyanotic induration is peculiar, and differs from the cyanotic induration due to heart disease. At a future meeting he will give a detailed account of the above lesions, and a more extensive analysis of the cases.

DR. TYSON could not speak from a systematic observation of a large number of autopsies in the cases of confirmed drinkers, but he remembered distinctly being surprised in several cases by the absence of cirrhosis, where he confidently expected to find it.

DR. WILSON said that Anstie in the article on Alcoholism in Reynolds's *System of Medicine*, had called attention to the comparative infrequency of contracted liver in confirmed drinkers. This observer, in an extensive outpatient practice in London, had seen large numbers of cases of alcoholism, but very few among them presented the physical signs of cirrhotic (contracted) liver. The experience of the staff at Blockley Hospital sustains this view. There, many of the patients are soaked with alcohol, but even among those whose death is directly or indirectly due to alcoholic excess, fatty liver is much more common than contracted liver.

DR. OSLER thought the experience of pathologists and morbid anatomists, with histories of patients, is not of the most satisfactory character, he often having had cases to dissect where he knew very little of the history. Before saying these cases were chronic alcoholics, Dr. Formad should present more specific statements about them. His own experience with livers in a large number of autopsies on cases of chronic alcoholism, had led him to divide them into four classes: 1. Those in which the condition of the liver is pretty satisfactory; some of these cases may take alcohol for many years and yet the liver pass muster; 2. Fatty cirrhotic livers; the cirrhosis may not, perhaps, be distinct to the naked eye, but plainly shown by the microscope; this is the largest class; 3. Hobnail livers; these, he would say, were much more common than in Dr. Formad's series; 4. Hypertrophic cirrhotic livers. The difference between his observations and those of Dr. Formad, might possibly be accounted for by the difference in the form of alcoholic beverage taken. He had not observed the special form of kidney described by Dr. Formad. In reply to a question, he said, in order of frequency he would place them, fatty cirrhotic, hobnail, hypertrophic cirrhotic, apparently normal.

DR. S. SOLIS COHEN said there are certain theoretical considerations which suggested themselves in this connection. The text-books teach that the lesions of alcohol are of two kinds, sclerosis and steatosis. It is known that in some organs the fibrous change precedes the fatty one. The latter is the higher grade of degen-

Digitized by Google

eration. The subjects of Dr. Formad's autopsies were confirmed whiskey soakers, in whom one would expect to find more intensity of degeneration than in those whose use of alcohol, though persistent and excessive, was not so outrageous. Another point which had not been alluded to, is the fact, that some lesions may result from a local action of the poison upon the tissues, while others may be due to its systemic action. No study of the subject can be complete in which these points are overlooked.

DR. RANDALL suggested that the point touched upon by Dr. Osler,—the character of alcoholic beverage,—might be very important. In Vienna, among beer drinkers, he had found the fatty liver much more common than the cirrhotic; while in England, where much gin is drank, and he should suppose in Scandinavian countries, where they drink strong spirits altogether, the cirrhotic liver is doubtless comparatively frequent.

DR. MUSSER had recently had to go over the records of the Pathological Society, especially in liver diseases, and had found the total experience of different observers the same as Dr. Formad's, and also in those cases cirrhosis was caused not so much by heavy drinking, as persistent drinking of spirits on an empty stomach.

DR. FORMAD presented the

SAC OF AN EXTRAUTERINE PREGNANCY.

The woman from whom this was removed had not suspected that she was pregnant. She was in perfect health until twelve hours before death, when she was suddenly seized with excruciating pain in the left groin, rapidly followed by collapse. On opening the abdomen it was found to contain at least a gallon of partly clotted blood. About the middle of the Fallopian tube was the sac with a rent in its posterior wall. This sac was one inch in diameter and contained clotted blood and placental tissue. The uterus was twice its normal size. The fœtus was not found.

NEW YORK STATE MEDICAL ASSOCIATION.

Second Annual Meeting, held in the hall of the Murray Hill Hotel, New York, Nov. 17, 18, 19, and 20, 1885.

TUESDAY, NOVEMBER 17TH.—FIRST DAY.

MORNING SESSION.

THE Association was called to order at 9.30, A.M., by the President, DR. JOHN P. GRAY, of Utica.

The committee of arrangements reported that there were forty-nine scientific contributions, four addresses, and several contributions to the study of pneumonia, to be presented before the Society. The number of papers presented last year was fifty.

In the report of the council, it was recommended that papers, which are to appear in the volume of transactions of the Association, be not previously published in the medical journals.

THE TREASURER'S REPORT

showed the total receipts for the year to be $2461; balance in treasury from last year, $683. Deducting disbursements for the year, there remained a balance of $193. For the library fund, the surplus from anniversary subscriptions last year was $630, $315 of which was placed to the account of the building fund. Excluding disbursements, there remained in the library fund $31. $80 had been subscribed for a binding fund.

DR. L. D. FERGUSON, of Troy, offered some

AMENDMENTS TO THE BY-LAWS,

to be acted upon at the next annual meeting. They referred chiefly to the abolishment of the office of corresponding and statistical secretary, the appointment of a librarian by the council, and striking out certain words as to the qualifications of those becoming members.

THE PRESIDENT, DR. JOHN P. GRAY, then read his address, taking for his subject

THE RELATIONS OF THE STATE TO MEDICAL SCIENCE.

He reviewed the educational policy of the State of New York, which is confined principally to supervision of the common schools and of the normal schools in which teachers for the common schools are trained. The duties of the board of regents were briefly referred to. Law schools, medical schools, scientific schools, etc., are corporations sustained by private contributions or earnings, and are individual enterprises, receiving no grants from the State. He then asked the question, What is proper legislative interference with this class of institutions, which represent scientific education and research? That the State itself should undertake such education as a public measure and for public policy, constitutes a serious question in political economy, and for this State, for the present at least, that question has been answered adversely. Legislative control over the medical schools of this State is not demanded by public interest. It was not intended to dispute the power of the Legislature to regulate medical education and declare what shall constitute a doctor in medicine; but the fact was that the Legislature exercised its power only in the way of fostering, protecting, and advancing the interests of medical science up to giving the best opportunities to schools for attaining this end, and at the same time, as far as possible, allowing the individual entire freedom of special study and of the means for acquiring knowledge of medical science. The State had not, and could not, adopt any particular school or system of medicine as opposed to others. It is the part of wisdom to give the widest latitude to discussions wherever matters of opinion seem to be in conflict. The giving to the physician certain powers which the State had conferred upon him is the highest endorsement which the State can give the profession. The State has left the culture and development of medical science to the medical profession alone, and has granted the right to incorporate societies and associations in order to maintain its unity of work and for its elevation and progress.

With regard to the services of the medical profession to the public, little need be said. The physician's services are sought by the people in the same way that the services of the lawyer or other members of the community are sought.

The author then came to the matter of granting diplomas, and the control of this power by the State. His views were adverse to any such proposed change. The State did even attempt to regulate the compounding and sale of drugs and nostrums. As the State had nothing to do with the teaching in the schools, so it should have nothing to do with the examinations.

Digitized by Google

What possible efficiency such a proposed Board of Examiners could have in benefiting medical science, the profession, and the people, did not appear. Such a change would transfer students who come to the medical colleges of New York from all over the country, and from foreign countries, to the schools of Boston, Philadelphia, etc. The schools have done excellent work in elevating the standard of medical study, and while there is room for further improvement, to seek it in the guardianship of the State is an error. It is true also that preliminary education should be better, and this demand also promises to be met as soon as the advance of the times will permit.

THE REPORTS OF THE DIFFERENT BRANCHES

of the State Association were then read, from which it appeared that a large number of papers on different subjects connected with medical science had been read, and other work had been performed. The President of the New York County Medical Association, Dr. C. A. Leale, also read the report of the annual labors of that Society.

ADDRESS IN STATE MEDICINE.

DR. ALFRED L. CARROLL, President of the Section in State Medicine, then read his address.

He reviewed briefly State medicine, or sanitary medicine as it existed in ancient times, and said that many excellent rules were in force among the Israelites which would be of practical utility in sanitary matters if adopted at present. State medicine, in its comprehensive sense, includes all the medical interests of the State. But after popular estimation, the term has a narrow significance; it is applied more especially to practical administration of sanitary science to the protection of public health. Even with this limited definition, preventive medicine has presented its claims with greater vigor than other specialties. Modern sanitation may be defined as applied physiology. The sanitarian should be primarily an accomplished physician. But he should superadd to his medical knowledge some theoretical, if not practical, knowledge of architecture and engineering. He should know how to detect defects therein, and be competent to suggest remedies to be carried out by the artisan.

Dr. Carroll then pointed out some of the conflicting opinions of sanitary men regarding what constitutes sanitary conditions. The superstructure of public sanitation has to be built upon the laws of personal hygiene. It follows that enlightenment in this direction must originate with physicians. As was the seed sown by medical schools, so would be the harvest of public health. How have these schools fulfilled this condition? The author said he would grant that many of them furnish the opportunities for a pupil having the means and ambition to make use of them to gain the necessary education; but what is needed is an enforced education in all important branches, not leaving their study optional with the student. The author named the studies and time required for study in force in England, and said that, while the work seems formidable, it will also be seen that the knowledge to be acquired is not more than every physician should have when he comes to discharge his duties to the public and to private patients. In his official relations, Dr. Carroll had had the opportunity to learn what are the acquirements of persons who seek positions on boards of health, and the answers by men graduated from regular medical schools were often absurdly erroneous. Now and then there were marked exceptions, even in remote country districts.

He thought a weakness in the State and local boards of New York existed in the short term of office, and in the time spent in inducting new men into strange duties. The need for a preliminary education and a higher and more thoroughly enforced medical education was pointed out.

NEWS ITEMS.

WASHINGTON.

(*From our Special Correspondent.*)

CHOLERA IN ITALY.—The U. S. Consul at Palermo, Italy, informed the Department of State, in a dispatch dated September 23, 1885, that the new cases and deaths from cholera had diminished since the 19th of September, the cases and deaths on that day being 258 and 185 respectively. The new cases and deaths on the 22d were 190 and 96 respectively. Up to the 23d, there had been 1279 cases, and 780 deaths.

Adverting to previous correspondence on the subject, he says, that it may be proper to say now, that the authorities, at his request, furnish him each morning with a statement of the cases and deaths of the preceding day, and that he is keeping a daily record of the thermometer and barometer, as well as of other matters which he deems of importance in connection with the epidemic, and which will be submitted in a general report upon the termination of the epidemic.

Under date of October 12, he further says, that since his last dispatch there have been 2658 new cases of cholera, and 1313 more deaths therefrom, in Palermo, making the total number of cases and deaths thus far 3937 and 2093, respectively.

The new cases and deaths of the previous day, as officially reported to him, were 110 and 51, respectively. In this connection it may be proper to state, he says, that the disease appears to have been decreasing for some time, and that if the cool and rainy weather which has obtained for some days should continue, it will disappear for the present. It is estimated that from sixty to seventy thousand people left the city since the beginning of the epidemic.

As an example of the difficulties experienced by persons leaving the city, he says that it may be of interest to state that Mr. Ignacio Florio, upon the appearance of the scourge, proceeded to his wine establishment in Marsala, as a precaution. He reached the place with great difficulty, narrowly escaping death at the hands of the infuriated country people en route. Upon reaching the outskirts of Marsala, he was met by the authorities and informed that he could not enter. It was, however, finally agreed that he should be allowed to enter his own grounds and kept therein, under guard, for a period of fifteen days. The Consul says, that as to wealth and position, Mr. Florio holds about the same relation to Palermo that Mr. W. W. Corcoran, one of our wealthiest and most prominent citizens, does to the people of Washington.

The United States Consul at Algiers, Africa, transmits, under date of October, 1885, a copy of a decree received from the Governor-General of Algeria, dated October 12, 1885, concerning the cessation of quarantine impositions and observances, and medical visits aboard all vessels coming from any French ports in the Mediterranean. He reports the health of Algiers and the districts as excellent, no cases of cholera or contagious disease of any kind having been reported during the summer.

The following is a verbatim translation of the decree:

"*Government-General of Algiera, Decree.*

Art. I.—"All ships coming from French ports of the Mediterranean, and arriving in Algeria with a clean bill of health, will be immediately admitted to the port without being submitted to the medical visit."

Art. II.—"The prefects of the three provinces and the maritime sanitary service, are charged with the execution of this present decree."

INSPECTION ON THE CANADIAN FRONTIER.—Surgeon Henry W. Austin, of the United States Marine-Hospital Service, who is now in charge of the inspection service now in operation on the Canadian frontier of the United States, for the prevention of the introduction of smallpox into this country, has made the following report to the Supervising Surgeon-General, dated Burlington, Vermont, November 10.

I have the honor to report that I completed the inspection of all Vermont Stations November 6th, and then returned to Burlington. Considerable complaint was heard that only a part of the Montreal baggage was disinfected at our station, and that it must be done at the points of destination. To satisfy local and State health officers, and in order that every possible precaution might be taken, I issued an order to all Vermont inspectors, and all inspectors on duty at Rouse's Point, thoroughly to disinfect all Montreal baggage, and this is now being carried out. Each station has a well-equipped fumigation building, where the baggage is opened and hung up on hooks, and allowed to remain in sulphurous acid gas for from four to twelve hours, according to the nature of the articles to be disinfected. Three pounds of sulphur are burned in one thousand cubic feet of space. The baggage is then carefully put back into the trunks, which are then checked and sent to their destination. Very few certificates of vaccination are at present accepted by our inspectors, but the arm is examined instead, and all are vaccinated when considered necessary. Large quantities of freight, consisting of household goods, are disinfected at each station. This is generally done in a freight car which is suitable for the purpose.

To illustrate the faithfulness and thoroughness with which the work is done aboard the trains, and the various means resorted to by certain emigrants, I will cite a few incidents. At Ogdensburgh, New York, an Indian of some Canadian tribe, was met on the ferry by our inspector, and he was asked the question whether he had been vaccinated. He replied, "Indian had not been vaccinated, and not propose to be." He was informed that he would have to return unless he allowed the inspector to vaccinate him. He reluctantly consented, and when the vessel arrived at port it was found that he had baggage that required disinfection. To this he strongly objected, but rather than have it returned, gave it over to the inspector, who put it in the fumigation building. He waited and watched the process with great interest, and as soon as the door was opened plunged into the room where the smoke was so dense that nothing could be seen, but returned in a second (well fumigated), but nearly suffocatd. He finally received his baggage and started. He immediately got drunk and was put in the lock-up by the city authorities, and was returned to Canada the next morning, he being without means of support.

On one of the trains a woman slipped by the inspector and entered the water closet. She was allowed to remain there two hours, and then a brakeman rapped for her to come out. She refused to do so, and had to be taken out by force. She was vaccinated, and allowed to pass. Passengers will mutilate their own arms, and produce the wound as evidence of vaccination. They have been detected in doing this, but it does not often succeed. They frequently wipe off the virus after they have been vaccinated, and always, when they are discovered, must submit to revaccination. On certain railroads, twenty per cent. of all passengers are vaccinated.

The fumigation of baggage is performed by the baggage-masters of the different roads, as they requested that they be permitted to do the work, as they were responsible for the baggage, and would be obliged to oversee the work and look after checks and shipping. This, of course, is done under the direction of the sanitary inspectors, but we are obliged to pay the men for this work, and they are subject to our orders. In this connection I would like to inform you that the railroad authorities of the Central Vermont, the Grand Trunk, the South Eastern, and the Passumpsic, have given us every facility to inspect passengers, baggage, and freight, and have assisted and supported our inspectors by every means in their power, and deserve the thanks of the Service and the community generally.

The inspection of trains is a difficult work, but it is being done as thoroughly as it is possible to do it. The inspectors are doing their work well, as I believe the result will prove. I have been with each inspector in making his trip to Canada and return, and am satisfied that all understand their duties, and are doing them well, and satisfactorily to all intelligent and unprejudiced persons.

PROFESSOR VIRCHOW ON THE CONGRESS DISSENSIONS AND THE AMERICAN MEDICAL ASSOCIATION.—At the recent celebration of the Berlin Medical Society, of the 25th anniversary of its organization, the President, Professor Virchow, in the course of his address took occasion to speak of the aims and scope of the Society, and in this connection referred to those of the American Medical Association, and its relation to the present deplorable condition of the International Congress organization.

He said: I have always held the opinion, and as early as the reform movements of 1848 gave expression to it, that if physicians wished to occupy an influential position, an association, of all things, was most necessary, in which they could, alone, find protection, and which could be made effectual by the energetic coöperation of its members. It has been recently attempted to extend

Digitized by Google

still further this effort at organization, so as to include all Germany, and thus to increase the influence of the profession. But I do not see now that anything is to be accomplished in this way. I think much more will be accomplished if the societies are maintained which naturally exist, and which local conditions demand, provided these are sufficiently strong each to say, we are the representatives of the entire body of physicians of our locality. The larger we grow, the more influential will this Society become, so that, at least for Berlin, it will prove that it is representative. We do not desire to be recognized as the representatives of all Germany, we do not wish to go beyond our own locality, but we desire to set an example and to furnish strong testimony of that which we represent in our own proceedings.

Of what may result when these aims are lost sight of, we have at this moment a mournful example in America. You know your delegates to the International Medical Congress held last year at Copenhagen, were instructed to invite the Congress to hold its next session at Berlin. We were outvoted, I am sorry to say, by the coöperation of our German colleagues. The Congress decided to go to America. What is the result? A situation which at this moment makes it extremely dubious whether an International Congress in America is possible. While the individual societies of that country, to some extent like ours, consider science their shield and their defence, and have endeavored to create an organization in which the eminent representatives of American medicine shall also appear as the representatives of the coming Congress—the American Medical Association, a vast society of practising physicians, extending throughout the land, usurps the control of the organization of the next session of the Congress, and creates such confusion that, I am informed, verbally and by letter, that no one at present is able to see his way out of the difficulty. Now, how did this dilemma originate? In the fact that the American Medical Association has set up a Code of Ethics, so called, and that with this code of professional ethics the admission to the Association is so broadly extended that entrance is free to all manner of dubious individuals. Hence has it resulted that, instead of eminence, mediocrity has come to the front, and that this Association, where the code is concerned, concerns itself more with forms than with principles.

May I not then well say that we are proud of our organization, by virtue of the care which we exercise in electing new members, and that we have, in this way especially, guarded against the necessity of forming a code of ethics, which every upright physician should in fact carry in his own bosom, and if he transgresses it, he should be restrained both by the example and admonition of his colleagues? This has been our conviction, thus have we regarded the Association, so do we regard the great associations of physicians. With us, no necessity has been found to establish special codes, or protective measures to secure us against the actions of dishonorable associates. Our unwritten code of ethics, without extreme measures, has become firm, and it behooves us to make it firmer and firmer, and from this it will result that we will be independent of the State and Government, and go through life as free men, and representatives, not only of a "craft," as the law designates us, but of a free art to which we have elevated our craft.

THE LACKAWANNA COUNTY (PA.) MEDICAL SOCIETY AND THE CONGRESS ORGANIZATION. — At the stated monthly meeting of the Lackawanna County Medical Society, held on November 10th, attention was called to a circular, which had been widely distributed through the State, soliciting support for the action of the New Orleans meeting of the American Medical Association regarding the organization of the Washington meeting of the International Medical Congress. Resolutions were then adopted condemnatory of this action.

THE AMERICAN PUBLIC HEALTH ASSOCIATION will hold its thirteenth annual meeting in the city of Washington, beginning on Tuesday, December 8, at Willard's Hotel Hall.

The Executive Committee have selected the following topics for consideration at said meeting:

1. *The best form in which the Results of Registration of Diseases and Deaths can be given to the Public, in Weekly, Monthly, and Annual Reports.*
2. *The Proper Organization of Health Boards and Local Sanitary Service.*
3. *Recent Sanitary Experiences in Connection with the Exclusion and Suppression of Epidemic Disease.*

Also, the *Lomb Prize Essays.*

1. Healthy Homes and Foods for the Working-classes.
2. The Sanitary Conditions and Necessities of School-houses and School-life.
3. Disinfection and Individual Prophylaxis against Infectious Diseases.
4. The Preventable Causes of Disease, Injury, and Death in American Manufactories and Workshops, and the Best Means and Appliances for Preventing and Avoiding Them.

In addition to other able and comprehensive papers expected to be presented at this meeting, the Secretary has received notice of the following from the able and well-known writers named below:

Forms of Tables for Vital Statistics. By Dr. J. S. Billings, LL.D., U. S. A., Washington, D. C.

Sanitary and Statistical Nomenclature. By Dr. E. M. Hunt, Secretary State Board of Health, Trenton, N. J.

Statistics of Consumption in Rhode Island for a Quarter of a Century. By Dr. Charles H. Fisher, Secretary State Board of Health, Providence, R. I.

The German System of Physical Training. By Dr. E. M. Hartwell, Johns Hopkins University, Baltimore, Md.

School Hygiene, Public and Private. By Dr. William Oscar Thrailkill, of San Francisco, Cal.

Sanitary Protection of New Orleans, Municipal and Maritime. By Dr. Joseph Holt, President State Board of Health, New Orleans, La.

Maritime Sanitation. By Dr. S. T. Armstrong, U. S. M. H. S., Memphis, Tenn.

Smallpox in Canada, and the Methods of Dealing with it in the Different Provinces. By Dr. P. H. Bryce, Secretary Provincial Board of Health, Toronto, Ont.

The Debit and Credit Account of the Plymouth Epi-

Digitized by Google

demic. By Dr. Benj. Lee, Secretary State Board of Health, Philadelphia, Pa.

An Epidemic of Typhoid Fever. By Dr. C. A. Lindsley, Secretary State Board of Health, New Haven, Conn.

Experiences in Disinfecting Sewers. By Dr. O. W. Wight, Health Officer, Detroit, Mich.

Progress of Health Work in Kentucky. By Dr. J. N. McCormick, Secretary State Board of Health, Bowling Green, Ky.

Observation on the Cape Fear River Water as a Source of Water-supply: A Study into the Character of Southern River Water. By Dr. Thomas F. Wood, Secretary State Board of Health, Wilmington, N. C.

The Virus of Hog Cholera. By Dr. D. E. Salmon, D.V.S., of Wilmington, D. C.

Hygiene of the Dwelling. By George N. Bell, C.E., of Newport, R. I.

The Proper Disposal of the Dead. By Dr. John Morris, of Baltimore, Md.

The Relations between Microörganisms and Cells. By Dr. A. C. Bernays, St. Louis, Mo.

The Layman in Sanitation. By Dr. W. H. Watkins, of New Orleans, La.

Who is Responsible for the Iniquities of the Third and Fourth Generations, and How Shall They be Avoided? By Dr. R. Harvey Reed, Secretary State Sanitary Association, Mansfield, Ohio.

Carelessness the Cause of Disease. By Dr. W. John Harris, of St. Louis, Mo.

The Committee on Disinfectants will present quite a voluminous report (printed), embodying their investigations and conclusions on the subject of disinfection and disinfectants. This report will be one of great public interest, and will probably call forth much interesting discussion.

The headquarters of the Officers and Committees will be at Willard's Hotel.

Applications for certificates to enable members and those intending to become members, and their families, to obtain the reduced rates offered by the various railroad lines to Washington, should be made without delay, to the Committee of Arrangements, J. C. McGinn, Secretary, Washington, D. C.

The Committee of Arrangements will issue a circular, giving full information regarding reduced railroad fare, hotel rates, etc., in ample season before the meeting.

Reports received from various quarters indicate that the forthcoming meeting will be largely attended, and one of national interest and importance. The subject of the restriction and management of epidemics at the present time is of sufficient importance alone to bring together a large and able body of sanitarians.

PROPOSED PERIODICAL CONGRESS OF RUSSIAN SURGEONS.—Professor Skilasovski, of Moscow, writes to the *Vratch*, urging the importance of regular meetings of Russian surgeons every two or three years, to be held alternately in St. Petersburg and Moscow, for the purpose of keeping the knowledge of provincial surgeons up to date.—*The British Medical Journal*, October 17, 1885.

THE WILLIAM F. JENKS'S PRIZE.—The widow of Dr. William F. Jenks has presented, as a memorial of her husband, to the College of Physicians of Philadelphia, in trust, five thousand dollars, the interest of which is to be triennially awarded for the best essay offered in competition upon some subject connected with obstetrics and gynecology. The prize is to be known as the William F. Jenks's Prize.

THE PUBLICATIONS OF THE GERMAN IMPERIAL BOARD OF HEALTH.—The publications of the Imperial Board of Health of Germany now take place on a new system. Every week there is issued a journal containing sanitary information and news, whilst from time to time there are to be published in supplementary quartos the scientific memoirs which represent the laboratory work of the institution. Hitherto these have appeared in completed volumes at intervals of about two years. There has already appeared the first instalment of the new issue, "Arbeiten aus dem Kaiserlichen Gesundheitsamte," Erster Band, Erstes und Zweites Heft. Preis 6m. It contains (1) a report upon the Condition of the Berlin Water-supply, edited by Dr. G. Wolffhügel; (2) Methods of Milk Analysis; (3 and 4) Experimental Researches, etc., on Swine Fever and Preventive Inoculation, by Drs. Lœffler and Schütz; and (5) the Vaccination Statistics for Germany for 1882.

THE LATE DR. THUILLIER.—The remains of the late Dr. Thuillier, member of the French Cholera Mission to Egypt, where he fell a victim to that disease in 1883, arrived at Marseilles on the 7th of September, and were immediately forwarded to Amiens, his native town, where they were interred at the expense of the State on the 14th instant. The funeral ceremony took place in the presence of the Minister of Public Instruction, the Prefect of the Somme, the Mayor of Amiens, and of M. Pasteur, who pronounced an oration over his late pupil and friend.—*The Lancet.*

PROFESSOR VIRCHOW ON ACCLIMATIZATION.—At the recent Congress of German Naturalists and Physicians held at Strasburg, Professor Virchow gave an address on acclimatization. He said that he would not discuss the political question as to the propriety of Germany forming colonies, but would point out how wide was the scope for scientific investigation into the subject, an inquiry which might influence State measures. He drew attention to the Amsterdam Congress of Colonial Medicine last year as evidence of the growing desire to learn more concerning the conditions of life and the changes experienced in the human organism under altered climatic influences. When an individual goes to a very different climate he is mostly at first uncomfortable, and after some weeks finds his organism regain its equilibrium; he has accommodated himself to new conditions; his organs have endured material change; he suffers from climatic indisposition or disease. Although the French and English have published much upon the subject, yet researches upon the special changes that precede the onset of disease are entirely wanting. On the other hand, the clinical study of tropical disease has been very much advanced. Whoever studies acclimatization must do so with a view to establish certain geographical limits of ethnological provinces analogous to botanical and zoölogical provinces. The Professor next proceeded to inquire how far the white races are

Digitized by Google

known to be capable of acclimatization, and showed that the Semitic are much more capable of it than the Aryan races; and amongst Aryans, the southerners (Portuguese, Spanish, Maltese, etc.) are more so than the northerners. Mixed races with strong Semitic admixture are more easily acclimatized than the pure Aryan stock. These races have developed in North America, the French in Canada, the Yankees in the United States, the English in Australia, but not in its northern, hotter parts. All these inhabit latitudes not far removed from the European, and yet they often become sterile, and the population decreases. Individuals born in the new country of the immigrant population never exceed three generations—for example, the English in India; and in spite of attempts to consolidate the Aryan colonization of the Indies by means of sanitary measures, it does not succeed. Medical officers of the navy and merchant service, and others, should study these conditions in the light of physiology. What is it that is most at fault? Is tropical anæmia a diminished formation or an increased destruction of blood? Tropical anæmia is found not only in regions where malaria, pernicious relapsing fever, dysentery, or yellow fever prevails, but it occurs apart from these diseases. This increase in blood disintegration excites a great tendency to diseases of the liver, and the liver is the main point of attack for diseases of acclimatization. To investigate the particular kind of disorders induced by acclimatization in individual organs is, Professor Virchow said, a paramount duty imposed upon German science. It does not depend upon special examples, but on the scientific determination of the conditions of existence for the vulnerable race of emigrants.—*Lancet*, Oct. 10, 1885.

OBITUARY RECORD.—DR. A. T. KEYT, one of the most prominent and esteemed physicians of Cincinnati, Ohio, died, at his home, November 9, 1885.

Dr. Keyt possessed great mechanical skill and was the inventor of a cardio-sphygmograph, with which, by the study of the heart and pulse, he obtained distinguished recognition both in this country and Europe.

NOTES AND QUERIES.

RETARDED DEVELOPMENT OF THE VACCINE PUSTULE.

To the Editor of THE MEDICAL NEWS.

SIR: I send you a case of retarded appearance of the vaccine pustule:

S. G., twenty-five years of age, was vaccinated on October 9, 1885. The matter used was animal virus. At the end of twelve days, there being no sign of the vaccination taking, she was re-vaccinated on the same arm, with the result of the first point of vaccination taking in a very marked manner, while the point of second vaccination healed up as a simple scratch.

Should you consider the above account of enough importance to publish, I shall be much pleased.

Resp. yours,
E. J. MORRIS.

PHILADELPHIA, 2203 ST. JAMES PLACE,
November 12, 1885.

BINAURAL STETHOSCOPES.

SPEAKING of an improved form of binaural stethoscope, Dr. W. A. Edwards says, in THE MEDICAL NEWS for November 7: "That binaural stethoscopes have not received from American physicians the attention that they demand is in part due, I think," etc. This sounds rather strangely, in view of the fact that the binaural stethoscope is the invention of an American physician; and was in use in the United States for a long time before it became known elsewhere, and, even now, is by no means so commonly met with in Europe as it is in this country. F. A. CASTLE.

NEW YORK, 55 EAST FIFTY-SECOND STREET.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM NOVEMBER 10 TO NOVEMBER 16, 1885.

BAILEY, E. L., *Colonel and Surgeon.*—Relieved from duty as Attending Surgeon, San Francisco, California, and ordered for duty as Medical Director, Division of the Pacific and Department of California.—*S. O. 260, A. G. O.*, November 11, 1885.

NORRIS, BASIL, *Lieutenant-Colonel and Surgeon.*—Ordered for duty as Medical Director, Department of the Columbia.—*S. O. 260, A. G. O.*, November 11, 1885.

MCKEE, J. C., *Major and Surgeon.*—Ordered for duty as Attending Surgeon and Examiner of Recruits, Boston, Massachusetts.—*S. O. 260, A. G. O.*, November 11, 1885.

VOLLUM, E. P., *Lieutenant-Colonel and Surgeon.*—Ordered for duty as Medical Director, Department of Texas.—*S. O. 260, A. G. O.*, November 11, 1885.

SMITH, J. R., *Lieutenant-Colonel and Surgeon.*—Ordered for duty as Attending Surgeon, New York City.—*S. O. 260, A. G. O.*, November 11, 1885.

ALEXANDER, R. H., *Lieutenant-Colonel and Surgeon.*—Ordered for duty as Medical Director, Department of Arizona.—*S. O. 260, A. G. O.*, November 11, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING NOVEMBER 14, 1885.

KINDLEBERGER, DAVID, *Medical Director.*—Granted leave of absence to June 30, 1886, with permission to leave the United States.

WIEBER, F. W. F., *Assistant Surgeon.*—To remain on Receiving Ship "Vermont" until May 15, 1885.

SAYRE, J. S., *Assistant Surgeon.*—Detached from Naval Hospital, Mare Island, and ordered to the "Omaha."

DIXON, W. S., *Surgeon.*—Detached from the Coast Survey Steamer "Hassler" upon reporting of his relief Passed Assistant Surgeon D. O. Lewis, and wait orders.

LEWIS, D. O., *Passed Assistant Surgeon.*—Detached from Naval Rendezvous, San Francisco, and ordered to relieve W. S. Dixon, Steamer "Hassler."

DUNGAN, J. S., *Medical Director.*—Ordered to Naval Rendezvous, San Francisco, to relieve Passed Assistant Surgeon D. O. Lewis.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING NOVEMBER 14, 1885.

URQUHART, F. M., *Passed Assistant Surgeon.*—Upon closure of Cape Charles Quarantine Station, to proceed to Norfolk, Virginia, for duty. November 5, 1885.

BATTLE, K. P., *Assistant Surgeon.*—Resignation accepted, as tendered, by the Secretary of the Treasury, to take effect November 25, 1885. November 3, 1885.

WHEELER, W. A., *Passed Assistant Surgeon.*—To proceed to Ontario, Canada, on special duty, November 11, 1885.

URQUHART, F. M., *Passed Assistant Surgeon.*—To proceed to Baltimore, Maryland, with Steamer "Manhattan," and then rejoin station, November 12, 1885.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

CAISSON DISEASE.

A Clinical Lecture delivered at the Pennsylvania Hospital, November 24, 1885.

BY ARTHUR V. MEIGS, M.D.,
PHYSICIAN TO THE HOSPITAL.

(Reported by Charles Baum, M.D.)

GENTLEMEN: The patient I shall now bring before you is suffering with a disease which, until within a few years, not only was unknown, but did not exist. He has caisson disease, which is a term we use to express the train of symptoms produced by working in compressed air.

Of late years, in building the piers and abutments of bridges, and in digging tunnels deep down below water-level, engineers have made use of a contrivance called a caisson, which is in effect nothing but a diving-bell. An air-tight iron shell is constructed of the size and shape of the pier or abutment to be built. This shell may be about nine feet in height, and is made very strong with stays and braces of wood and iron, and it is, of course, open at the bottom. On the top is laid the masonry, the whole surface being covered, except small spaces, which, as the pile of masonry becomes higher and higher, assume the appearance of wells, and are technically termed shafts. The object of a contrivance of this kind is to render it possible to carry the foundations of a bridge through the soft and unstable material which often forms the bottoms of rivers, down to rock or other suitable bed. This, you can readily understand, is easily accomplished by sinking the caisson with its superincumbent load of masonry to the bottom of the river, preventing the water's filling the chamber by keeping it constantly pumped full of air.

When once the structure rests upon the bed of the river, men in the air-chamber dig away the sand or mud underneath, and it is removed by the suction of sand-pumps and discharged through the shafts at the top. The means of entrance to and exit from the air-chamber is through what are called air-locks, which are air-tight iron chambers, placed either at the top or bottom of the shafts. These chambers have two doors, one communicating with the outer air, and the other with the air-chamber of the caisson, and these are of such size that the workmen and building materials can pass through. There are also pipes provided with stop-cocks, one communicating with the air-chamber, and the other with the outer air, by means of which the air-pressure can be made to equal that which exists within the chamber or that outside. When a man wishes to enter the air-chamber, he goes to the air-lock, and, the door into the outer air being open and that communicating with the chamber closed, he goes into the lock, and, closing the door behind him (both doors being now shut), he turns the stop-cock and allows the compressed air from the air-chamber of the caisson to rush in until the pressure within the lock is equal to that in the chamber; then it is only necessary to open the door of entrance to the chamber to be able to go in. In coming out the process is simply reversed.

There has been published within a few years a *History of the St. Louis Bridge*, by Prof. C. M. Woodward, which contains many interesting facts connected with the results of exposure to compressed air upon the human economy. Some of the supports of this immense bridge across the Mississippi River, the building of which was one of the greatest feats of modern engineering, are carried down to a greater depth below the water-level than are those of any other bridge in the world. The experience gained in the building of this bridge, the piers of which were sunk so deep, being about one hundred feet below the surface of the water when the river was at its ordinary level, was very extensive and valuable.

When a man goes into the air-lock to gain admission to the air-chamber of the caisson, and the compressed air from the chamber is allowed to rush in, as the air-pressure increases there is often produced violent pain in the ears with bleeding from the nose or even from the lungs. If the pain in the ears is not relieved by blowing the nose, or taking a swallow of water and thus inflating the middle ear through the Eustachian tube to equalize the pressure upon the two sides of the drum membrane, such a man should beat a retreat, and not expose himself to further increasing air-pressure. These are the worst effects produced while going into the compressed air; and while in, and even when working in the chamber exposed to the full effects of the increased air-pressure, no dangerous effects are experienced. It is after coming out from the caisson that the effects are produced.

The symptoms, as described by Dr. A. H. Smith, in Pepper's *System of Medicine* (vol. iii. p. 854), are, "in the order of their frequency, intense neuralgic pain in one or more of the extremities, and sometimes in the trunk; epigastric pain; nausea and vomiting; more or less complete paralysis, which may be local or general; headache; vertigo; and coma." The disease is usually very sudden in its onset, men having often been stricken down with paralysis while mounting the stairs after coming out from the air-chamber, or while walking to their homes. Dr. Smith had charge of the health of the men employed in the caisson-work at the building of the East River Bridge, in New York. The piers of this bridge were not carried down to so great a depth as were those of the St. Louis Bridge, and only three men died from exposure during its construction. Dr. Smith states that heavy men with a tendency to corpulency were much more likely to be unfavorably affected than were lank and spare men. Prof. Woodward (*loc. cit.*, page 257) states that about 600 men were employed in

Digitized by Google

the air-chambers of the St. Louis Bridge, and of these 119 are known to have been more or less seriously affected with the disease, 14 died, and 2 were crippled. "Two-thirds of those taken sick at the east pier were attacked immediately on coming out, either on the stairs or as soon as the top was reached. In other cases the men were generally attacked within half an hour. . . . As a rule, chance visitors had no personal sufferings to report beyond a 'frightful pain' in their ears while making the first passage of the air-lock.

"It must not be forgotten that *no one was attacked while under pressure*, nor while pressure was being applied; the fatal moment was when the pressure was removed, or within half an hour from leaving the air-chamber" (*loc. cit.*, pp. 257 and 261).

Post-mortem examinations were made of the bodies of quite a number of men who died of this disease, and the most constant lesions found were intense congestion of the brain and spinal cord and of their membranes, and often some arachnoid effusion. There were also found in some instances hemorrhages in the kidneys, and sometimes injected areas, or even patches of ecchymosis in the stomach, intestines, and bladder.

There have been various explanations offered of the mode of action of compressed air in producing all these effects upon the human economy. Prof. L. Bauer (*St. Louis Medical and Surgical Journal*, new series, vol. vii. pp. 234–245) suggests that hyperoxygenation and increased waste of the organic structures take place in the body while it is in the compressed air, and that, at the same time, the blood necessarily carries more carbonic acid and other effete material. So long as the person continues in the compressed air, the hyperoxygenation goes on, and no ill-effects are experienced; but, when the pressure is removed, the hyperoxygenation immediately ceases, and the accumulation of waste materials acts as a poison to the system.

Dr. A. H. Smith thinks the deleterious effects are due to the changed condition of the circulation, the blood being driven, while the subject is in the caisson, from the surface toward the interior of the body where the pressure is less, and that it is forced from all the more compressible tissues into the more solid ones, and particularly into bony cavities. When the pressure is removed, the blood rushes toward the surface, and into all the vessels which have been emptied by the pressure until they are so distended that their walls become paralyzed. The vessels of the brain and spinal cord, which lie in bony cavities, are naturally the most affected, and they are so distended that "the vaso-motor system becomes out of use."

Dr. Jaminet, who had charge of the men who worked in the caissons at St. Louis, attributed the disease to the increased and rapid tissue-waste which, he said, took place while the men were subjected to the pressure. He found that the men breathed twenty-one times a minute, instead of eighteen, as is natural, and that an increased amount of urine was passed while they were in the compressed air, and that it contained an abnormally large amount of urea. They sweated, too, when the temperature was lower than that at which men will usually sweat. Where men work under a pressure of four and a half atmospheres, as was the case at St. Louis, he said that at each breath the man took four and a half times as much oxygen into the lungs as when subjected to the usual pressure, and consequently, he argued, the body-waste went on four times as fast.

François and Paul Bert are quoted by Dr. A. H. Smith (*loc. cit.*, p. 855) as suggesting that the morbid phenomena may be due to the liberation of air or nitrogen in the vessels, which had been absorbed while under pressure, the bubbles of gas thus liberated obstructing the bloodvessels.

C. M. Woodward (*loc. cit.*, p. 258) expresses the opinion, "that *the vital energies of the men taken sick were to a great extent paralyzed by loss of heat.*" This loss was due:

"1. To the expansion of the air in the lock, while coming out.

"2. To the expansion of the free gases and vapors within the body, when relieved of the abnormal pressure.

"3. To the liberation of the gases held in solution by the liquids of the body.

"4. To the severe physical effort of climbing the stairs."

He lays great stress upon the fact, that all the men felt very cold upon coming out of the compressed air, and says, that, although, while in the chamber, everyone had a feeling of exhilaration, upon coming out "the increased vital energy gave place to a very low ebb of vitality and an all-pervading sense of frigid helplessness."

It would seem likely that the real state of the case is, that the effects produced are due, not to any one of the causes suggested alone, but to all of them acting together, or to varying combinations of two or more of them. The very name which has been given the affection indicates that it is only a term which has been used for convenience to express a varied and complicated train of symptoms, which probably may be due to a great variety of causes. It appears to be certain, that there is, while under increased air pressure and afterwards, great loss of body heat, increased tissue-waste, and driving of the blood from the surface toward the interior, and subsequent rapid expansion of all the liquids and gases in the body, those within the bony cavities having the least favorable opportunity for recovering their stable equilibrium. These causes must act to different degrees and in different ways to produce the variety of effects that have resulted in the men who have at different times been affected.

There is a story told in the St. Louis Bridge history, that upon one occasion a visitor opened a brandy flask while in the chamber, and then, after securely screwing on the lid, thought no more of it until he got back to the outer air, when his flask exploded with considerable violence. It is also said, that if the Eustachian tubes are obstructed, rupture of the drum membrane is certain to take place upon going into the compressed air, and this has occurred. No more telling story could be told than that of the brandy flask, to show what must occur with every liquid and gas contained within the human economy upon coming out from the compressed air-chamber, and when it is remembered that sometimes as little as three to five minutes only were allowed to pass between the time when men were in the air-chamber, subjected to a pressure of four and a half at-

Digitized by Google

mospheres, and their coming out to the usual pressure, the wonder is, not that so many were sick in consequence, but that any escaped unharmed.

The patient I show you is suffering with the disease in one of its milder forms. He is twenty-eight years of age, and, as you see, is a strong and muscular-looking man. He was employed at the bridge which the Baltimore and Ohio Railroad Company are building below Gray's Ferry. What the depth is at which they are now working I do not know, but this man labored in the caisson only during one shift, and he tells us that they are now engaged in concreting, which shows that the work must be near its completion, for concrete is only used after the caisson reaches the bed upon which it is to rest; first to make a level surface for it to rest upon, and lastly to fill the caisson itself.

This patient went to work at four in the afternoon and labored until twelve at night, having had a rest at the end of the first four hours, when all the men on the shift came out of the chamber to eat lunch. He had never done any work of the kind before, and after coming out from the caisson at first felt no ill-effects. At this bridge the air-locks are placed at the top of the shafts, and the men climb out by means of ladders; the ascent is made, therefore, while still in compressed air and not after coming out, as was the case at the St. Louis Bridge. This man walked to his boarding-house, which was about half a mile away, and as he climbed the stairs to go to bed he felt some pain in the calves of the legs. He was hardly in bed, however, and had not even slept, when he was seized with pains through and above and below the knees, which were so violent that he was forced to jump from bed. The greater part of the rest of the night he passed in rubbing his legs and limping about the room, the pain being so severe that he could not lie still for a moment. Thirty-six hours later he came to the hospital, and was admitted the day before yesterday, so it is now three days and a half since he was attacked, and the attack came on, as I have told you it usually does, within a short time after leaving the compressed air-chamber. This man is only now beginning to have any comfortable degree of freedom from pain. When he was first admitted he was given, as is the custom in the ward with all patients who are not too ill, a warm bath, and he says it gave him great relief. An examination of the urine showed that it contained a very small amount of albumen but no tube-casts could be found.[1]

In none of the accounts of this disease that I have been able to obtain, is any mention made of the urine having been examined for albumen, and this is very strange, for *à priori* there seems every reason to expect that it would often be present, for there have been found, at some of the autopsies made, hemorrhages in the kidneys, and all authorities speak of the high degree of congestion of the internal organs that exists.

The prognosis in this disease should be a guarded one, if the patient manifests any of the more severe symptoms. It can probably be said, however, that any one who is not severely affected within twenty-four hours after exposure to the cause of the disease is safe, for in all the men attacked the symptoms seem to have reached their maximum within that length of time. By this statement is meant the primary symptoms, for it goes without saying that injury of the brain and spinal cord might set up inflammatory conditions which would take much longer to limit themselves; witness the fact that one of the men stricken with paralysis at St. Louis, lingered for nearly a year, to die finally.

The treatment which should receive our closest study and promises most fairly in the results we may hope to attain, is to be sought for in the direction of preventive medicine. No more striking exemplification of the truth of this statement could be desired, than what I can tell you in connection with the building of the St. Louis Bridge. In building the east pier thirteen of the men employed died; in building the east abutment, which was sunk five feet deeper than the east pier, being carried down one hundred and twenty-seven feet below high water mark, only one man died. The causes of this great discrepancy in mortality are not far to seek; in building the east pier, the men after coming from the air-chamber found themselves at the bottom of the shaft, in the open air, chilled to the bone from having come out of the compressed air, and exhausted with having worked under the unnatural pressure, with about one hundred and ninety steps to climb before they arrived at the surface of the earth. When the east abutment was constructed, a steam elevator was used to transport the men from the bottom of the shaft to the top, and at this time, too, the physician in charge had had further opportunity to study the effects of compressed air, and stringent regulations were made to oblige the men to keep themselves in the best possible condition.

All the men who applied for employment at the caisson work were examined, and those found to have any physical disability were rejected. Each man was made to lie down upon a bed for half an hour after coming out of the caisson, before he was allowed to go home. Beef tea was served to them, and no man was allowed to go to work except he had had a good meal within an hour or two before. No ill-nourished or poorly clad men were employed. Dr. Jaminet insisted very strongly upon the very great importance of taking food shortly before going to work in the caisson. The effects of these hygienic regulations and the use of the elevator, which probably did more to save the men than any other one thing, were abundantly demonstrated by the results, for, as already stated, thirteen men died during the construction of the east pier, while but one life was lost during that of the east abutment, which was sunk five feet deeper.

Prof. Woodward suggests the following rules (*loc. cit.*, p. 262) as proper for the management of men working in compressed air.

"1. Men must be sound and well fed. They should eat a hearty meal about one hour before entering the air-chamber.

"2. The periods of labor should be diminished as the pressure increases; say, to two watches of two hours each per day under a pressure of four atmospheres.

"3. Men should have perfect rest and warmth for half an hour after coming out. This includes the use of an elevator.

[1] A few days later the albumen had disappeared from the urine, and the patient was discharged declaring himself well.

Digitized by Google

"4. The pressure in the air-lock should not be increased more than six pounds per minute, nor diminished more than four pounds per minute. If, when the pressure is increasing, any one has pain in his ears which cannot be removed by blowing his nose, or by swallowing water, the inlet of air should be stopped and the man sent out.

"5. Every man, just *before leaving the air-chamber*, should be required to swallow about a pint of hot coffee, tea, or soup.

"6. There should be separate air-locks for *entrance* and for *exit*. The *exit* air-lock should be provided with heating apparatus, which should maintain a proper temperature and furnish direct heat to the bodies of the men."

The treatment of the disease itself must be varied as one or other of its phases is presented. The pains can be best relieved by the use of morphia, and Dr. Smith recommends its free use; half a grain to be given at first and a quarter of a grain every hour afterwards until relief is obtained. Epigastric pain can usually be relieved by an alcoholic stimulant with ginger. Dr. Smith highly recommends the use of ergot, and gives a drachm of the fluid extract when there seems to be threatening of paralysis. If there is paralysis, it must be treated upon general principles. A hot bath has been found greatly to relieve the pain, but its use is discountenanced by Dr. Jaminet, as paralysis came on in some of his cases while they were in the bath. It has been said that prompt relief of the symptoms may be obtained by returning the subject to the compressed-air chamber, but this would be difficult to manage in most instances, as there are often many stairs or high ladders to be climbed before it could be accomplished, and there would be no facilities for taking care of sick men; besides that they would be much in the way of the further prosecution of work.

REMARKS ON EXCISION OF THE HIP.[1]

BY L. M. YALE, M.D.,
OF NEW YORK.

AN apology is perhaps due to the Society for again bringing up so well-worn a subject as excision of the hip. But as it is one upon which surgical opinion is far from unanimous, its consideration must be always in order until the value of the operation is better settled than it yet is. The more recent views concerning tubercle and the rise of antiseptic surgery have stimulated the resort to excision in hip disease. Aseptic methods have now been long enough employed for considerable experience to have been accumulated as to their effect upon the ultimate results of this operation. This paper is the outcome of an attempt to ascertain from the periodical literature of the last six or seven years, what this experience has been, and whether any conclusions could be drawn from it regarding the indications for resection in hip disease. Although tolerably familiar with the difficulties of the question, I confess that I was somewhat surprised at the scantiness of the material which came to hand that was valuable for exact comparisons.

The grounds upon which resection of the hip is urged as preferable to non-interference are usually three:

First. That it directly saves life.

Second. That it shortens treatment, and by so doing, lessens risks both vital and functional.

Third. That it gives better functional results.

There can be no manner of doubt that the operation often saves lives that otherwise must certainly have been sacrificed. Such operations *in extremis* have been aptly compared to tracheotomy in like conditions. Under such circumstances failures should not be counted. Every success should be esteemed a clear gain, and even prolongation of life and mitigation of suffering be reckoned in favor of the operation. About such resections there is probably no question. The inquiry is rather this: comparing cases as nearly as possible similar, at what period, or under what circumstances, do the results obtained by excision become preferable to those gained by less radical measures? And it may be here said, that a good deal that has been said regarding the relative value of early or late operations is rather beside the question; for there is little doubt as to their comparative success. The issue is between the operation at all and conservative methods, and the former is clearly indicated whenever it can be shown to give better prospects for life than the latter.

The value to be set upon resection, therefore, depends very largely upon what is held to be the natural tendency of the disease, and upon what success can be gained by conservative treatment. And right here, at the start, we find a divergence of views so wide as to go far toward explaining the unsettled condition of opinion regarding the operation. The most gloomy statements come from German authors.

Thus, Billroth gave the death-rate of his cases, some of which were followed after leaving the hospital, at 31¼ per cent., taking, if I understand correctly, all cases. Hueter,[1] from hospital records alone, gave 26¾ per cent. The two lists united give 28⅔ per cent. Nowhere else is the death-rate set so high when all stages of the disease are considered together. From reports for several years of the Orthopædic Hospital in this city, I find that the deaths and discharges on account of incurability together make an annual average of about 4¾ per cent. of all cases treated. Gibney's statistics[2] from the Hospital for the Ruptured and Crippled, give for 288 cases a mortality from all causes of 12½ per cent. Taylor's statistics,[3] which give (deducting one case of violent death) 2 deaths in 92 cases, or 2⅙ per cent., cannot be fairly quoted here, as they are drawn from a private practice among well-to-do people.

Although exsection has of late been done quite early in the disease, yet it would be obviously unfair to make any comparison between the death-rate of these collections of cases in all stages, and the most favorable operative statistics. Again, although exsection is frequently done when destructive changes are recognizable in the joint, but before suppuration is evident, I know of no extended statistics of the corresponding cases treated conservatively. A few cases will be mentioned further on. But regarding suppurative coxitis, we have more distinct expressions of the results of experience and some statistics. Here again, Hueter's estimates exceed others in gravity. While acknowledging the absence of exact information, he states that he should be surprised if statistics would show that more than 50 per cent. of cases that reach the "second florescence stage" (the stage of flexion, adduction, and inward rotation) ever were healed. And he further states his belief that "suppuration of the hip-joint, if the cases in which a single small abscess forms and quickly closes again, and also the cases of scanty suppuration in the granulations of synovitis hyperplastica granulosa are subtracted, is a nearly absolutely fatal process."[4] Volkmann[5] is by no means as hopeless. Ollier[6] thinks that "the greater part of the suppurative coxalgias of children, may be cured by methodical expectation, aided by the resources of hygiene." Taylor lost 2 out of 24 suppurative cases, or 8⅓ per cent. This, as before stated, was in private practice. The Committee of the Clinical Society of London[7] set the mortality cases of suppurative hip disease treated expectantly at 33½ per cent. from all causes, or leaving out causes unconnected with the disease, at 31⅙ per cent. Cazin[8] gives the result of 80 cases treated at the hospital at Berck, sent from a Parisian hospital after they had failed to improve there. All but 10 of these were grave cases, and 5 per cent. were already albuminuric when received. The statistics cover five years; 55 per cent. were cured, 12½ per cent. died, 7½ per cent. were benefited, and the remaining 25 per cent. were not cured when removed. This remarkable success for cases of such severity, may perhaps be not fairly introduced here, as the patients, although belonging to the hospital class, were at Berck under excellent hygienic influences, and were systematically treated.

Gibney[1] out of 80 cases of hip disease, cured without mechanical treatment, found 48 that had had abscesses. No percentage of mortality can be made here, as the total number having had abscesses is not known; but this number of recoveries under a plan of the purest expectancy, shows that suppurative coxitis cannot be nearly as grave an accident as some have estimated it to be. As an offset, however, may be mentioned 19 cases recorded by Caumont,[2] treated conservatively, of which 12, or 63.1 per cent., died.

From these discordant figures and opinions it seems to me fair to conclude that their disparity is not the result of the bias of different observers, but that in some communities or districts circumstances may so influence the course of disease, as to make an actual difference in the facts. as well as in the interpretation of them. To express an opinion, therefore, as to the average mortality of suppurative coxitis may be hazardous, or even presumptuous. Nevertheless, my own observations lead me to accept the more moderate estimates as the more nearly correct, and I consider that the rate set in the Clinical Society's report is amply large; that is to say, that the death-rate does not exceed 30 per cent. even among the poor, at least as we know poverty in this great city. In private conversations, Drs. Gibney and Shaffer, of this city, both of whom have had unusual facilities for knowing the results of hip disease among the poor, expressed the opinion that the estimate I have given is very liberal and would considerably exceed the facts.

Now as to the death-rate of excision. Leisrink's[3] often quoted tables set it at 63.6 per cent., but this high figure is reached by setting aside all unhealed cases as worthless; which is a source of error, as many such cases go through the same course as unoperated cases and reach an ultimate cure, perhaps by ankylosis, after a long time. If all of Leisrink's cases had been included, his death-rate would have been 57.9. Sayre's[4] table gives 72 cases (2 being still under treatment) with 25 deaths, or 34.7 per cent. Culbertson's tables contain 418 cases, with 174 deaths, or 41.62 per cent. If uncertain cases, 30 in number, are excluded, the percentage will be 45.61. All these collections contain cases kept under observation for quite a long time, and this death-rate is by no means that of operation. Culbertson gives only 29 as immediately resulting from the operation, that is 6.93 per cent. of all cases. This is interesting as showing that even before the advent of anti-

septic surgery, the operation, as such, added but little to the general mortality from hip disease.

Many lists published since the beginning of antiseptic surgery, contain cases treated in both periods, and often no attempt is made to separate them. Thus, Cowell,[1] in reporting 65 operations of his own, says "I now perform the operation antiseptically," but the results are all grouped together. It does not apppear that these cases were followed beyond the hospital. There were 7 deaths among them, or 10.77 per cent. Three cases above 18 years of age all died. Of the 62 cases below 18 years only 4 died, or 6.15 per cent. Here should be placed the statistics of the Clinical Society's report, before quoted, which gave a mortality of 40 per cent., or excluding deaths from causes unconnected with the disease 37.7 per cent. Holmes's[2] list, given in his well-known address in surgery, of operations done in British hospitals, belong to the five years ending 1878, a period during which antiseptic precautions were coming into use. They should probably be considered as mixed operations. It does not appear how long the cases were followed, but of 215 cases, 40, or 18.6 per cent., died, and 57, or 26.5 per cent., failed. Caumont,[3] whose statistics are commendable for the care with which cases have been traced for years after they left the hospital, and carefully classified, records 42 cases with 26 deaths, or 61.9 per cent. Only 5, or 11.9 per cent., died from the operation, the remaining 50 per cent. were from progressive caries, amyloid changes, and tuberculosis. His death-rate before antisepsis was 66 per cent.; since antisepsis, 41 per cent.

Of operations entirely antiseptic, Volkmann[4] reports 48, with but 4 deaths, or 8⅓ per cent. Two only of these (from shock) were strictly deaths from operation; the third, after two months, was from thrombosis, and the fourth, after three and a quarter months, from hemorrhage, from ulceration of an artery, due to a suppurating scrofulous gland. Volkmann estimates that 8 to 10 would subsequently prove fatal from the progress of the disease, which would run up the death-rate to 25 to 30 per cent. Korff[5] reports 16 deaths out of 33 cases treated antiseptically (48.48 per cent.), the death-rate diminishing steadily as the methods were improved, being 75 per cent. when Lister only was used, 52.63 per cent. with a modified Lister, 30 per cent. with a bichloride and salt gauze dressing. Grosch[6] bases his statistics on 166 cases treated antiseptically; 120 of these were observed to the end, with 44 deaths, or 46 7 per cent. He divides his cases into three stages. The first contains those operated on with unruptured capsule and slight changes in the joint; the second, cases with abscess and fistulæ; the third, cases with long suppuration, and extensive destruction of joint, with great debilitation. In the first class there was for children no death-rate; for the second, it was 24.1 per cent.; for the third, 67.5 per cent. Further, he found that for the period 1876–82, after antiseptic methods were well established, the death-rate was 9 per cent. less than for the period 1870–75, in which these methods were forming. Quite recently Alexander[1] gives the results of 36 operations apparently all done and dressed antiseptically (chloride of zinc and Lister). One case only died of operation (shock), 2.77 per cent., 10 more from disease. Total death-rate, 30.55 per cent.

It will at once be seen that statistics gathered in such different ways and to bring out different aspects of the question, cannot be closely compared with hope of an exact result. But if I have correctly apprehended the general import, it is this, that the mortality after resection of the hip-joint has materially diminished since the introduction of antiseptic precautions, and that the diminution corresponds very closely to the death-rate formerly chargeable immediately to the operation itself. Take the extensive tables of Culbertson; setting aside uncertain cases, he had a total death-rate of 44.58 per cent.; deducting deaths from operation (6.93 per cent.), we have 37.65 per cent., which is very nearly the same as Grosch's 36.7 per cent. for 120 completed cases under antiseptic treatment. In other words, asepsis has nearly abolished the risks from wound complications, and the death-rate is reduced very nearly to that from the uninterrupted disease when the operation has failed to arrest it.[2] And as it has been shown that in cases that heal, the period of healing is shorter than when antiseptics are not used, the danger of amyloid changes may be slightly lessened. Thus much has been gained by perfect antisepsis: in weighing the chances in any given case, we need no longer put much stress on the dangers of the operation itself, except perhaps the one element of shock, which the prolonged extirpation of diseased and suspected tissues necessitated by the thoroughness of modern surgery, sometimes favors. It seems then fair to say, that whenever the disease in its natural course assumes an aspect threatening to life resection is indicated, provided none of the less radical operations (drainage, gouging, etc.) can remove the danger.

It has just been mentioned that very early operations done while the changes in the joint are slight and the capsule unruptured have given no death-rate or almost none. But, on the other hand, the disease itself has practically no death rate at this stage. Occasionally, general or visceral tuberculosis may occur thus early, but rarely. Amyloid changes and exhaustion do not enter here as causes of death. It does not appear then that there is thus early any vital indication for excision. The early operation has been urged as vitally indicated in forestalling tuberculosis, and the other attendant risks of morbus coxarius by cutting short the disease. If it could be proven that such prevention actually followed the operation, it would be a weighty argument. As Grosch points out, tuberculosis is still the com-

[2] At first sight, it would seem as if more had been accomplished, but, as Grosch's statistics contain very early cases of a kind that scarcely appear in Culbertson's, the comparison is not quite upon an equal basis.

Digitized by Google

monest cause of death. König[1] maintains, as the result of a large experience in excision of all kinds (117 in three and a half years), that the hoped for immunity from tubercular infection has not been gained by antiseptic resection; of 25 deaths out of his operations, 18 were from tuberculosis, and, in addition, 9 cases, not yet dead, were hopelessly tuberculous; in all, 21.5 per cent. of his cases; and of 21 hip excisions, 10 (47.6 per cent.) died of tuberculosis in four years. In the debate on König's paper, some disagreement with his views was expressed, but Esmarch essentially confirmed them. Caumont[2] distinctly states that he found no preventive effect in his cases. Of 26 cases of scrofulous origin, treated by expectancy, he lost 5, rather less than one-fifth, from tubercular diseases; of 12 resected, he lost 4, or one-third. Others may have better results, but the prophylactic effect cannot be very decided if such marked exceptions occur.

Nor is it clear that destructive changes in the joint without evident suppuration often present a vital indication for excision. A vicious form of caries, characterized by great suffering and great destructiveness of tissues, without much pus-formation (caries sicca), is probably best met by resection. But of ordinary caries this is not true. It is a matter of common experience to find cases in which the destructive process is evidenced by the misplacement of the trochanter, which go through the whole course to recovery without any external evidence of suppuration. Caumont has taken the trouble to place such cases by themselves in his report. Of those treated expectantly, 25 per cent. died; of those exsected, 50 per cent.

It is not until suppuration has taken place that any vital indication for resection appears. Even here, I believe, the dictum of Hueter[3] is far too sweeping when he says: "I hold resection of the hip-joint in coxitis to be indicated as soon as an extensive suppuration of the joint manifests itself, or as soon as the course shows that the termination in suppuration can be no longer prevented. Such a statement, however, is the natural outcome of his extremely gloomy views of the results of suppuration. If the opinion I have expressed as to the prognosis of suppurative coxalgia is anywhere near a correct one, resection is only indicated in a minority of cases. The indication comes not from the existence, but from the persistence, of suppuration. If it persists, after the drainage of the abscesses, and under the best hygienic resources the patient can command, particularly if fever attends the suppuration, then exploration of the joint is indicated by incision or dilatation of existing fistulæ, with resection or a less extensive extirpation of the diseased parts, as the condition found may demand. And this should not be delayed after the system shows distinct depression from the suppurative process. To wait until the operation is the only escape from impending death, is to err on the side of ultra-conservatism. I have not mentioned necrosis or sequestra in the joint, because under such circumstances some operation for the removal of the dead bone is imperative. Likewise, if perforation of the acetabulum with pelvic abscess exist, we have no resource but resection. True dislocation of the femur with suppuration of the hip-joint is of very rare occurrence in ordinary hip disease, and the indication for excision, often urged in this connection, is rather orthopædic than vital.

A few words may be said regarding the second claim, that, namely, resection shortens the period of treatment, and that it diminishes the risks, both vital and functional. This is true of those cases that heal promptly and soundly, but only of such. Besides those that are fatal, there is a long series of cases that neither die nor heal, but live for years with persistent fistulæ. In Leisrink's tables 12.5 per cent. were "unhealed;" in Holmes's, 26.5 per cent. were "failures." Such cases are now spoken of as "relapses." Asepsis favors prompt healing of the soft parts, and the union subsequently in many cases breaks down, and the old process is reëstablished under circumstances in no way improved. Just how frequent these "relapses" are, I cannot say, but they are often mentioned as "common." My own observations make them about 20 per cent. of all cases operated on. A friend, who was in Kiel in the past summer, quotes Neuber as saying that "about half" of his cases relapsed. This refers, I understand, to the reopening of the wound, with tubercular granulations of its edges. Many of these ultimately do well after excision of the diseased parts.

Lastly, as to function. It is far from proven that resection gives better average results than a "natural" cure. In the question, shortening is not the most important element; the shortening from resection is, on the average, greater than from natural cure, but not so very much. In a case not resected, but of such severity as to bring the operation into consideration, the growth of bone from the upper extremity will have been considerably retarded or arrested according to the degree in which the epiphyseal cartilage has been affected. In a case resected, the growth will be entirely abolished and some bone already produced must be sacrificed. Ollier[1] points out that although the total growth in length from the lower extremity of the femur amounts to about twice that from the upper, yet, during the first four years of life, the two ends contribute about equally, and that later the lower increases in activity until its work is, toward the end, about three times that of the upper. The prognosis as to length, then, will vary with the age at which excision is done; very early excisions giving much the greatest ultimate shortening. The leaving of the trochanter does not much affect this relation, for what it contributes to growth in length is mainly above the joint, and does not much increase the efficient length of the bone.

The atrophy from inactivity affects the whole limb, and is not materially different in cases resected from those left alone. If a resection were promptly successful, the advantage ought to be in favor of the operation as permitting more speedy use of the limb.

Again, a useful joint in a lower extremity must be stable as well as mobile. And, for most occupations, security in the support of the trunk is more essential than motion at any one joint. Mobility, with security at the hip after excision, is only obtainable when very strong fibrous attachments exist between the pelvis and the remains of the femur. The destruction from the disease, and the necessary extirpation of affected tissues, usually prevent the formation of attachments at once strong and flexible. Exceptions occasionally occur, and some very brilliant results have been obtained in which stability existed with very free motion.[1] Some very remarkable attempts at renovation of a hip-joint have occurred, and interesting specimens have been described.[2] Nevertheless, as a rule, the motion, if considerable, is combined with such feebleness of support that the femur rides up and down on the pelvis in the act of walking. "Flail-joint," in the usual acceptation of the term as meaning uncontrollable motion in various directions, is rare, and I do not remember to have seen it. It is this insecurity that has led some operators (Ollier, Caumont) to urge that if the operation is made very late, or in cases where much local damage has been done, if the patient must earn his living it is better to strive for ankylosis rather than mobility. *A fortiori*, the ankylosis of a natural cure—the limb, on the average, being longer than after excision—will give for such persons a more useful limb. The compensating mobility of the spinal articulations if the disease occurs in childhood is often marvellous. The most striking instance I ever saw is No. 31 in Dr. Sayre's tables of excision; the motion took place in the lumbar spine, not only antero-posteriorly, but laterally through a wide arc. Statistics (Grosch) show no better functional results for antiseptic operations than were formerly obtained.

Functional reasons strengthen the indication for the substitution, whenever possible, of the simple extirpation of diseased parts for formal excision, in that they disturb less the relations of parts. These less radical performances are, by the perfection of aseptic precautions, rendered safe, and the large removals of bone formerly necessary to prevent accumulations of pus and septic matter seem no longer essential. In the same direction, improvement of functional results may be hoped for by the employment in proper cases of the operative manœuvres in which a partial or temporary removal of the trochanter only is resorted to, the muscular attachments being little disturbed.[3]

Further, it should not be forgotten that good functional results as to position and motion can only be obtained by prolonged after-treatment. Neglect in this particular constantly produces great deformity; and the care required to secure these good results quite answers the claim already alluded to, that resection is a short road to cure.

The conclusion, then, to which the foregoing brings us is that exsection of the hip is indicated as a life-saving operation only, and that as it has not been shown that it can save from any dangers except those consequent upon prolonged suppuration, it is, with rare exceptions, only indicated when the suppurative process has evidently reached a dangerous point, and cannot be interrupted by any less serious operation.

THE LOCAL TREATMENT OF LARYNGEAL TUBERCULOSIS.[1]

BY BERNARD TAUBER, M.D.

WHETHER phthisis of the larynx precedes the pulmonary deposit or is only a sequence of the latter, is a question which I shall not discuss in this paper. A great many text-books on the practice of medicine still set forth the antiquated notion that topical treatment in this affection is not crowned with the success which we should anticipate, and the *nolle me tangere* plan is generally adopted. I think this is a fallacious doctrine against which I raise my earnest protest, and I can enumerate five cases of laryngeal phthisis of the first stage which are alive to day, after a lapse of ten years, and three cases of the second stage who lived three, four, and five years.

Having observed such favorable results, I take the ground that, *if laryngeal phthisis be observed in the initial or first stage and be properly treated, it can be arrested and sometimes cured.* In the advanced stages, by applying proper treatment to the parts, the patient can be made comfortable and kept up for some time.

Most authors on diseases of the throat recognize two stages of laryngeal phthisis. Clinically, three stages present themselves for treatment; pathologically, four stages are seen, namely: 1st, the stage of anæmia; 2d, that of tumefaction; 3d, that of ulceration; 4th, that in which necrosis or caries of the cartilages is present.

Examining the larynx in the first stage we find a marked anæmia—a paleness of the mucous membrane of a grayish hue, also a loss of adductive power in the vocal cords. Sometimes the latter may be congested. On physical examination, although we may find the lungs insufficiently expanded with diminished resonance, and although we may hear a prolonged expiratory breathing, the lungs may yet be comparatively free from disease. Patients in this condition will seldom seek for medical advice; only when local irritation in the throat has set in, is a laryngeal examination resorted to.

Having recognized the first stage, fortunately for such patients, little local treatment is required; stimulant inhalations of oleum eucalyptus, oleum pini or tinct. benzoini may suffice to allay the local disturbance in the larynx. Change of air and of scene is of paramount importance. There is no doubt that the various climates contain something for the arrest of phthisis in this stage; these are absence of damp soil, asepticity of the air, and dryness of the atmosphere. Outdoor life is the best tonic in phthisis; therefore a trip to New Mexico, Monterey, Mexico, or to Nassau (Bermuda Islands), with the

[1] Read before the Cincinnati Academy of Medicine, November 16, 1885.

Digitized by Google

intention of remaining there for several years, is requisite; it is, I may say, indispensable for restoration to health. Those who cannot undertake such an expensive treatment, should use at home compressed air inhalations, and, if tonics be indicated, granules of arsenious acid, hyphosphites and koumiss, etc., should be given them. In a large majority of cases it is in our power to arrest this first stage before the development of the graver symptoms.

If the case have progressed to the second stage, we note a thickening and tumefaction of the mucous membrane, generally covering the arytenoid cartilages on one or both sides, or invading the interarytenoid commissure. I have had good success in checking this tumefaction for three or four years by applying the galvanocautery knife, flat surface, to the swollen parts. The pain occasioned by the cautery was allayed by insufflation of morphia and gum acacia. To reduce the pain to a minimum, I now brush the parts several times before and after the use of the thermocautery with a ten per cent. solution of cocaine. We must not overlook, however, one cardinal point in this stage of the disease, namely, to keep the stomach in good condition, and to treat the subjective symptoms as they appear. For the cough and excessive discharge from the throat, I generally order the patient to inhale a few drops of chloroform and creasote, and insufflate the larynx with morphia and iodoform, or cocaine and powdered sugar.

In the third stage we have to combat an excessive cell growth—destructive ulceration goes on. All our efforts to arrest this progressive stage of the disease are futile. The principal complaint of the patients is the painful deglutition of liquids and solids; they resist the act of swallowing, and it is done only with the greatest reluctance. To allay this misery, insufflation of morphia alone or combined with iodoform is not efficient; the effects of this anodyne may last only a short time, say one hour. The recently discovered cocaine, so highly spoken of as a local anæsthetic, I have tried extensively and faithfully in this stage of the disease in solutions of 4, 8, 10, and 20 per cent., also in the form of powders insufflated to these ulcerated parts. I must confess that this great remedy has disappointed me. Its effects pass away very rapidly—in 25 to 30 minutes—and to keep up its effect it would be necessary for the patient to remain all day in the physician's office, in order to have it reapplied.

For several years I have studied and tried to correct this painful deglutition, and can recommend to the profession a simple and efficient remedy; the application of the following solution, applying it thoroughly to the ulcerated parts once or twice a day:

℞.—Acidi carbolici . . . . ℥jss.
Tinct. iodini . . . . ℥ss.
Glycerinæ . . . . ℥ij.—M.

This application produces a whitish eschar and gives to the thickened and ulcerated parts an artificial covering, a protection, and a prolonged anæsthesia is established. The patient experiences a burning sensation for a very short time; in a few seconds he is enabled to swallow liquids and solids. I have seen patients ten or fifteen minutes after this application drink a cup of tea or coffee, or a glass of beer, make short work of a tenderloin steak and mashed potatoes, and even eat a hearty meal.

The anæsthetic effect will last from eight to ten hours; therefore, if the patient gets one topical application in the morning, he will be enabled to eat two meals a day; and another application can be made in the afternoon or in the evening, to enable him to take his tea. Imagine the patient's comfort and gratitude!

It is not necessary for me to explain to you the anæsthetic action of carbolic acid. We all know that it lowers the sensibility to pain and touch of the parts to which it is applied. It will even permit free incisions without suffering. Further, the carbolic acid is a destroyer of the bacilli, and at the same time we have the cleansing and antiseptic effects of the iodine.

The question of tracheotomy arises as a remedial measure to overcome the great dyspnœa. This operation is indicated only in the second stage of phthisis laryngealis, in order to secure to the larynx rest from the movements of the muscles, cartilages, and vocal bands engaged in respiration and phonation. In the third and fourth stages I am decidedly opposed to tracheotomy. This operation was justifiable in pre-laryngoscopic times. We know that ulceration is present to a great extent; the cartilages of the larynx and trachea are prone to caries; the presence of a tracheotomy tube in such a locality only causes irritation of the trachea, and does not materially aid respiration and deglutition. All we could achieve by the operation is the prolongation of a miserable existence for a few days. Such a procedure should be resorted to only under the most exceptional circumstances.

In looking over the literature of this subject, I have nowhere found the mixture here recommended to you, and which I have used with the greatest success for the last ten years, described or mentioned as a topical application to the larynx for the production of continued local anæsthesia. I hope my *confrères* will give it a fair trial and report their results.

HOSPITAL NOTES.

DISPENSARY FOR NERVOUS DISEASES, BALTIMORE.

Service of JOHN VAN BIBBER, M.D.

CLINICAL NOTES.

Facial Paralysis (Right).

R. S., sixty years of age, presented himself for treatment, Oct. 16, 1885. Gave the following history: retired on night of Sept. 27, 1885, in good health. On arising next morning, found that he could not comfortably masticate his food, that his mouth was drawn over to left side of face, and that he could not close eye of right side; he experienced some pain on this side. On questioning, he denied having been exposed to draughts while asleep, or at any other time; he said, however, that his face had been swollen and painful for a week previous

Digitized by Google

to paralysis. On examination, found that all the muscles of the right side of face, supplied by the seventh nerve were paralyzed, for he could not voluntarily wrinkle his brow, close the eye, or move nose or mouth on this side. All the symptoms usually accompanying facial paralysis of a severe form were present. One symptom of particular interest was the hyperæsthesia of the right ear, indicating that the neuritis had extended high enough to affect some fibres of the auditory nerve.

The muscles were somewhat atrophied, and the temperature was below normal. There was no reaction whatever to faradic current, and only slight response to galvanic current. He was ordered to come daily for electric treatment, to rub the paralyzed muscles frequently, and to relax the overstretched fibres by pushing the side of face into its proper position.

After one week's treatment, it was found that some of his muscles would slightly reply to the faradic, after first using galvanic current. Patient was now ordered Van Bibber's hook and rubber muscle, and wore strips of adhesive plaster so adjusted as to support the lower fibres of the orbicularis. The above treatment has been persisted in up to date, November 9th, and patient's recovery is now assured, nearly all the muscles of the paralyzed side replying to faradic current. This is the result of above treatment for three weeks, begun three weeks after occurrence of paralysis.

Remarks.—In a case of facial paralysis in a patient 60 years of age, the prognosis is not as good as in younger subjects. The faradic contractility being lost, and interrupted galvanic not producing exaggerated reaction, prove that the origin of the paralysis is not central. I have reason to believe that if the patient had been unable to have the advantage of elastic apparatus and the bands of plaster to overcome the constant stretching of the paralyzed muscles, that his recovery would have been much delayed and a perfect cure extremely doubtful.

If massage is any advantage to a badly nourished muscle, certainly the physical aid in bringing about a more rational and relaxed condition of the over-stretched muscular fibres is a good element in the successful treatment of any paralysis where the opposite muscles are producing injurious traction. It does constantly what massage only does for a limited time, and in this case without the aid of some similar apparatus the good effect of the manipulation of muscles is soon lost in the injurious traction of the left facial group.

MEDICAL PROGRESS.

USE OF THE RECTAL LEVER.—MR. RICHARD DAVY has demonstrated the practical value of rectal compression of the aorta and both common iliac arteries in three instances within the last ten days. The first case was one of compression of the right common iliac artery for the removal of a recurrent growth involving the whole of Scarpa's triangle and the inguinal canal. The external iliac artery and vein were ligatured; so also were the superficial and deep femoral arteries and veins. The patient was a man aged twenty-eight, under Mr. R. Davy's care. Mr. Thomas Bond held the lever. In the second case, Mr. George Cowell amputated at the left hip-joint in a boy aged twelve, for sarcoma of the femur. Mr. Davy controlled the left common iliac artery. The third case was one of excision of the cervix uteri and adjacent parts for epithelioma, by Dr. Potter, in a woman, aged twenty-nine. Mr. Davy controlled the aorta for five or six minutes during Dr. Potter's manipulations. The total loss of blood during the three operations did not exceed seven ounces, and no rectal inconvenience has been experienced in either case.—*British Medical Journal*, Nov. 7, 1885.

NITROUS OXIDE AND OXYGEN AS AN ANÆSTHETIC IN LABOR.—The great advantages of nitrous oxide as an anæsthetic have induced various observers to endeavor to find a method of administering the gas continuously, so as to keep up the anæsthesia for a sufficient length of time for the performance of surgical operations. Paul Bert, some years ago, made experiments with animals in a chamber of compressed air, a mixture of nitrous oxide and oxygen being inhaled. He found that anæsthesia could be safely kept up for a long period; and he urged the construction of such chambers for operating on the human subject. Nothing of the kind, however, has, as far as we know, been attempted. In 1881, Dr. Si Klikovich, of Professor Botkin's clinic in St. Petersburg, made some experiments on himself, with a mixture of nitrous oxide and oxygen, in the proportion of 80 to 20, without any increase of atmospheric pressure, with a satisfactory result. He also used it for alleviating the pains of labor, and found it very successful and perfectly safe; the great objections to it being its expense, and the cumbersome nature of the required apparatus. Some months ago Professor Zweifel, of Erlangen, erected the necessary apparatus for the supply of the mixed gases to the accouchement ward of his obstetric clinic. He finds it best to administer the gases continuously during the latter part of labor, when the pains are most severe, not, as was practised by Klikovich, merely giving the gases when signs of an approaching pain appeared. Though this treatment had been adopted in sixty patients, no retardation of the process was ever observed. The patients were generally semiconscious; so that though they would answer if asked a question, they felt no pain, and were unaware when the child was born. In one case, where the woman screamed as a stitch was put in the perineum, she afterwards declared she had felt nothing. If this plan of administering nitrous oxide gas be really as satisfactory as Drs. Klikovich and Doederlein, in St. Petersburg and in Erlangen, have found it, surely there might be an apparatus constructed in some of our own lying-in hospitals. Probably, too, the mixed gases could be compressed in an iron bottle, and so made portable. If ever this plan should come into general use, the practitioner of the future, on being sent for in a midwifery case, will find himself obliged to carry, or get carried for him, very much more weighty impedimenta than the present pocket midwifery-case, or even than the most complete "obstetric bag." He will, however, have the satisfaction of knowing that he can really alleviate his patient's sufferings, instead of, as at present, having simply to look on, with folded hands, at agony which, being physiological, he can do nothing to relieve, at least, without running other risks, which, as a rule, he does not not feel called upon to do.—*British Medical Journal*, Nov. 7, 1885.

NEPHROTOMY FOR TOTAL SUPPRESSION OF URINE.—MR. CLEMENT LUCAS performed an unique operation in Guy's Hospital on October 29th. A woman, from whom he had removed the right kidney for total destruction of its secreting structure by large calculi and hydronephrosis, about four months ago, and who had made a rapid and complete recovery, was suddenly seized with great pain in the left kidney, followed by vomiting, headache, and suppression of urine. She passed urine last on Sunday morning, October 25th, between eight and nine o'clock; and, from that time till the operation on Thursday afternoon, no urine passed, and vomiting was persistent. Her medical attendant. Mr. Atkins, of Sutton, correctly interpreting the meaning of her symptoms, placed himself in communication with Mr. Lucas, and the patient was brought to London on Wednesday, October 28th. It was thought that the effect of diuretics in flushing the kidney might yet be tried whilst the patient was watched. These proved of no avail, and on Thursday afternoon, the patient having become drowsy and much weaker, Mr. Lucas cut down the remaining kidney, and removed from the pelvis a conical calculus, measuring seven-eighths of an inch by one-half in its greatest diameters. Total suppression had then lasted 102 hours. A free flow of urine took place at once through the wound, and the patient was relieved of her vomiting and drowsiness. Five days after the operation she was doing well and feeling comfortable. Mr. Lucas's case of nephrectomy performed on October 20th healed without suppuration or fever. The patient sat up for the first time on the eighth day, and is now convalescent.—*British Medical Journal*, November 7, 1885.

TREATMENT OF LUPUS.—A new method of treating lupus has recently been suggested by PROFESSOR C. GERHARDT, of Berlin, which may be said to be a direct outcome of the discovery of the bacillus of tubercle. Hitherto it has always been thought essential to use destructive measures in dealing with the disease, and whether by cauterization or by direct scraping out of the affected tissue the main object has always been the same. But of late years the presence of the tubercle bacillus in the lupoid patches has been constantly recognized, although in very small number. As many as twenty and thirty specimens have been examined by Professor Koch before the bacilli have been seen. Taking this fact into consideration with the extremely slow progress of some cases of lupus, Professor Gerhardt is led to the belief that while the bacillus is at work as a principal factor in the disease, some other element must be present which prevents the bacillus from spreading and multiplying with the rapidity which characterizes it elsewhere. He finds in the superficial situation of lupus and its consequent exposure to cold, the deterrent influence which hinders the spread of the microörganism. Acting upon this view, he has adopted a form of treatment whereby the influence of cold, by means of small ice-bags, can be constantly exercised upon the diseased surface, and he records some cases (*Deutsche medicinische Wochenschrift*, No. 41) which would seem by their results to justify the line of treatment, if not to prove the theory upon which it is founded. The advantages claimed for the method are these: that the disease is checked in the same or even a shorter time than by the ordinary means, and without any destruction of surrounding tissues, and that the activity of the tubercle bacilli is checked, if not altogether destroyed. To what extent the good results hitherto obtained will be permanent has, however, yet to be proved by the test of time.—*Medical Times*, November 7, 1885.

THE EMPLOYMENT OF POWDERED COFFEE AS AN ANTISEPTIC DRESSING IN MILITARY SURGERY.—DR. OPPLER (*Deutsch. milit. Zeitschr.*, 1885) proposes the employment of powdered coffee as a primary dressing upon the battlefield, especially in default of other antiseptics. The powdered coffee should be applied to the wound and covered over with a small quantity of soil, an air-tight antiseptic dressing thereby resulting. Former experiments of Dr. Oppler show that powdered coffee prevents putrefaction of blood, urine, foods, etc., and that it is a true antiseptic.—*Archives de Médecine et de Pharmacie Militaires*, November 1, 1885.

BELLADONNA AS AN AGENT TO PRODUCE TOLERATION OF THE IODIDE OF POTASSIUM.—M. AUBERT, in *The Lyon Médicale*, No. 13, 1885, proceeding from the fact that belladonna produces dryness of the throat, nose, and mouth, was led to employ it along with iodide of potassium as a preventative of the coryza which attends the long-continued use of this drug. His observations show that when the two remedies are used together intolerance is never experienced, and the iodide fails to produce its characteristic symptoms.

The quantity of belladonna necessary to produce such result is stated to be from one to two pills, each containing five-sixths of a grain of the extract.—*Annales de Dermatologie et de Syphilographie*, October, 1885.

MALARIAL GANGRENE.—DR. BLANC, in a contribution to the study of malarial gangrene, concludes:

1. Cold and serious pulmonary disease should be placed among those causes which play an important part in the production of local asphyxia and malarial gangrene.

2. Exposure of those suffering from malaria—their sudden transition from warm to cold countries—may occasionally produce local asphyxia and malarial gangrene.

3. The antiperiodics, quinine and arsenic, seem to constitute the best treatment for the complications attending the disease.

They may arrest and cause the local asphyxia to disappear completely; they may check and limit the gangrene, but here the specific action seems less sure and rapid than in the state of asphyxia. The well-known difference in the action of quinine upon visceral lesions, according as they are congestive or sclerotic, is here observed, though in a mild degree.

4. From a surgical point of view in the treatment of malarial gangrene it is advantageous to operate only when the progress of natural elimination has ceased.

The gangrene being dry, danger of infection is remote. The difficulty of at first distinguishing parts which are mortified and those simply the seat of prolonged local asphyxia, is a further reason for tardy operation.—*Archives de Médecine et de Pharmacie Militaires*, November 1, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, NOVEMBER 28, 1885.

UTERINE INVERSION FOLLOWED BY NORMAL PREGNANCY AND CURE.

A CASE of inversion of the uterus, in which this condition did not prevent pregnancy, and at some time during the latter, spontaneous restoration occurred, is reported in *L' Union Médicale*, October 13.

The story as told by DR. PARRELL, of Dieppe, is briefly as follows: The patient, twenty years of age, a primipara, was attended in her labor by a midwife, who stated that the delivery of the placenta was difficult, the cord was very short, and strong tractions upon it were necessary to remove the former. The uterus, after the placenta was withdrawn, was in normal condition. The following night the patient had violent pains, and straining efforts were made as though she were in labor. The next morning, about twenty-four hours after delivery, Dr. Parrell was called, because the woman had retention of urine. He found the uterus inverted, and efforts were then made, and also at other times within the next few days, to restore it, but without even partial success. In six weeks the patient was up, and by wearing a Gariel's air pessary could walk, or stand, with comparative comfort. At each menstrual period she suffered with dysmenorrhœa and some menorrhagia, but the flow was not alarming. One year after the accident, she called upon her physician, stating that she thought herself pregnant, having then missed her monthly flow once. He examined, and found the uterus still inverted. She was not seen again for four months, when vaginal examination showed that the uterus was no longer inverted, and auscultation detected the sounds of the fœtal heart. Four months subsequently she was delivered of a child, the accident following the first labor not being repeated.

Is the story credible? Velpeau said that he accepted the occurrence of the *vagitus uterinus*, because reputable persons asserted they had heard it, but if he heard it himself, he would not believe it. In this case, we think a good deal stronger proof than the statement of one individual, however intelligent and conscientious, must be adduced before the story can be accepted, and we wish the reporter had manifested a similar scepticism to that of Velpeau.

Three things in the narrative seem improbable, and a fourth is apparently impossible. First, the non-occurrence of severe menorrhagia is not the usual fact, at least in the absence of lactation, in case of uterine inversion: an inverted uterus suffers more readily from congestion, and exhausting hemorrhages follow, so that anæmia is the common result. Second, dysmenorrhœa is certainly not a probable accompaniment of uterine inversion. Third, spontaneous reduction of an inverted uterus is a very rare occurrence, there having been so far recorded, according to Denuce's statement in his *Traité Clinique de l'Inversion Utérine*, published two years ago, only fourteen cases: of course, the possibility of this event occurring in Dr. Parrell's patient, is not denied, but only its great improbability suggested.

Finally, we are asked to believe that the uterus remaining inverted, fecundation occurred, that the ovum was by some means detained at some point upon the surface of the organ, and a few weeks after the beginning of pregnancy the uterus restored itself, carrying the ovum from its external surface to its cavity, a detention and transportation which seem so utterly improbable, that the combination of the two may be regarded as impossible. It would be much easier to believe that the reporter committed an error of diagnosis, than that nature accomplished such wonders.

This, however, is not the first instance in which pregnancy is asserted to have occurred while the uterus was inverted. Chevreul, of Angers, communicated to Baudelocque such a case. He had recognized the inversion before the pregnancy, and found it still present after an abortion which happened at three months, an embryo three inches long being expelled. Chevreul thought that the pregnancy had taken place in a dilated oviduct. But such hypothesis is unnecessary if we admit the alleged facts in Dr. Parrell's case.

THE CURE OF ANGINA PECTORIS.

IN the *Bulletin Général de Therapeutique*, for September 30th, HUCHARD has an important communication on this subject. In the first place, he distinguishes most carefully the pseudo-anginal attack from the true, and his remarks upon treatment apply to the latter alone. He regards the disease as an affection of the arteries of the heart, and not a cardiac

Digitized by Google

neurosis, and quotes numerous facts in support of his position. As adherents to this view he claims Germain Sée, Potain, and others, and even Lancereaux, who formerly regarded it as a neurosis. Perhaps the majority of writers on the subject are of the opinion, which has had numerous supporters since the days of Edward Jenner, that the actual lesion of the disease is in the coronary arteries.

An arterial malady must be met by arterial medication, and as the blood-pressure is always increased in the affection, all remedies which heighten the vascular tension must be avoided, as ergot and digitalis. He refers to a curious observation of Wesley Mills, in which anginal attacks followed the local application of ergot. For the relief of the paroxysms, we have at our command amyl nitrite and nitro-glycerine, which cause vaso-dilatation, lowering of the blood-pressure, and increase in the vigor and frequency of the heart-beats. They relieve the angina alone, and are in no way curative, but Huchard believes that the iodides possess the means of so modifying the arterial condition, that a positive cure may be effected. In 1883 he reported six cases which had been greatly benefited by their use, and since then he has had twenty-five patients under his care, of whom fifteen have recovered completely, six have been much improved, and in four cases the effect of the treatment was negative. The possibility of any of these being pseudo-anginal cases was carefully excluded. This brilliant result he attributes in a great part to the action of the iodides on the sclerosed coats of the vessels. The chief element in success is perseverance in the treatment for many months, at least fifteen to eighteen; from fifteen to forty-five grains of the salt are taken daily, until some months have elapsed from the last attack. The administration of the drug may be kept up for as long as three years, to insure durable and certain recovery. He prefers the iodide of sodium for prolonged use, as the potassium salt, when employed for many months, has a weakening effect upon the heart; moreover, it is better borne and more readily assimilated.

Details are given of six cases, in which the results of the treatment, as narrated, are truly remarkable, and certainly justify the prolonged trial of the remedy in this terrible affection. The usual care must, of course, be exercised in these cases to regulate the diet, and remove all sources of mental worry and disturbance. The four cases of failure show that the remedy is not always curative, but in such instances the arteries may be in a state of calcification and past medication.

RUSH AS AN ALIENIST.

IN his recently issued volume, *On the Insane in the United States and Canada*, DR. D. HACK TUKE has an interesting preliminary sketch of Rush in relation to the insane. The *Medical Inquiries and Observations upon the Diseases of the Mind*, which appeared in 1812, was the first work on insanity issued in this country, and remains one of the most valuable of American publications on this subject. A fifth edition was published in 1835. While in some respects the views entertained by Rush, and the practice which he followed, did not differ very much from those in vogue at his time, Dr. Tuke claims for him that he distinctly recognized the corporeal nature of insanity, that he taught it to be a disease requiring medical, as well as moral, treatment, and that he gave to the profession and world an able exposition of the forms of mental disorder.

The extracts which Dr. Tuke gives in illustration of Rush's mode of dealing with refractory patients show how impossible it was even for so humane and gentle a man to free himself from the ideas and practices of his day. Still he was in many points far in advance of his time, if he did not quite come up to the standard of his noble contemporaries at the Bicêtre, and the York Retreat; for we find him advocating the employment of the insane, and taking active measures for the amelioration of the unfortunates in the basement cells of the Pennsylvania Hospital; and he seems rejoiced to be able to say that "the clanging of chains, and the noise of the whip are no longer heard in their cells."

After reading of his heroic treatment for mania, we wonder that any of the patients recovered—copious bleedings, purges, and low diet; and after the system was thoroughly reduced, "blisters, issues, errhines, the cold bath, and exercise"—and yet he seems to have been very successful.

The position taken by Rush in regard to moral insanity is that of advanced modern writers, and we are reminded of Maudsley, when, in his "Inquiry into the Influence of Physical Causes upon the Moral Faculty," he speaks of "moral derangement and of innate preternatural moral depravity, the result of defective organization."

Rush was an ardent temperance reformer, and was one of the first to plead for the establishment of curative institutions—*sober houses*—for dipsomaniacs. Only a few days ago, in recognition of his labors as a pioneer in this department, the interesting ceremony of planting a tree upon his grave was performed by one of the National temperance organizations.

Rush has been called the "American Sydenham," but Dr. Tuke prefers to call him the "American Fothergill," and he points out striking resemblances to his great London contemporary "in the independence of his medical practice; in acuteness of observation; in an enthusiastic love of the art of healing; in his incessant labor; in popularity as the

Digitized by Google

leading physician of the day in a great city; but, above all, in uniting with the functions of a physician the philanthropy which manifested itself in innumerable practical suggestions for the benefit of his kind."

POLYMASTIA.

ANCIENT fable taught that the Amazons burned, or compressed, the right breast in childhood, so that, its development being arrested, these warrior women could more readily use the bow. A less ancient mythology, for the cry, "Great is Diana of the Ephesians," was heard in the first of our centuries, represented Diana of Ephesus by a statue with two large, full breasts, and other breasts covering the chest and the abdomen; according to St. Jerome, the statue was the mystic image of nature, which is the mother and nurse of all living things. The Ephesian Diana, therefore, must be considered the first and best known example of polymastia.

Polymastia has been observed in both the male and in the female, but probably never was advantageous to either. Even a single supplementary breast, in at least one instance, was a woman's greatest misfortune, if the story as to Anne Boleyn be true; for she, who had a superfluous finger on each hand, had also a third breast, and it was this condition that aroused the hate of that most cruel of monarchs, Henry VII., a hate which could only be appeased by her death.

Polymastia is not a very rare anomaly. Puech has collected in France seventy-seven cases; in forty-six there were three breasts, in twenty-nine four, and in two five. Lichtenstein has in Germany collected one hundred and five cases.

If there be only one additional breast, it is usually below one of the other breasts, or in one of the axillæ; if two, they are generally in the axillæ; but if three, the third will be found above the umbilicus. The supernumerary breasts are usually pectoral, rarely are any abdominal, and in a few instances a breast has been found upon the thigh, upon the shoulder, and even upon the back.

Cicero found proof of divine wisdom, in that the number of breasts corresponded with the number of young born at one time; and hence a multiparous animal had many breasts, the sow and bitch being familiar illustrations. The problem of polymastia in the human female, probably never presented itself to his mind.

The presence of breasts in the human male is, according to Darwin, evidence that in the earlier stages of evolution lactation was performed by both sexes. Upon the same principle, polymastia would be considered an indication of atavism, a reversion to a former type, which, were it to become general, would disturb the very bones of Malthus.

DR. HOLMES AND HOMŒOPATHY.

SEVERAL years ago, DR. OLIVER WENDELL HOLMES delivered a series of lectures upon "Homœopathy and Kindred Delusions." In reference to the former, he remarked that the most scientific men see through its delusions at a glance, and that while it might be practised by shrewd men, and by honest men, rarely, it must be feared, by those who are both shrewd and honest: as a psychological experiment on the weakness of cultivated minds, he regarded it as the best trick of the century.

We have been led to refer to these earlier utterances of the wise, learned, and observant doctor, as to homœopathy, by finding in the December number of the *Atlantic Monthly*, a brief, incidental reference to the same subject from his gifted pen—a pen, which, not in malice, but in kindness and love of truth, has done so much to expose medical error, an Ithuriel spear, which penetrates disguises, and reveals the shams and falsehoods concealed by them. The reference made by Dr. Holmes to homœopathy, which we present, shows that his opinion of this delusion has been in no wise changed. The following is an extract from a letter written by a young lady to one of her female friends; the two being among the characters in "The New Portfolio." In this letter, after referring to the possibility of her becoming a doctor's wife, she says: "I don't know but I should be willing to let him try his new medicines on me. If he were a homœopath, I know I should; for if a billionth of a grain of sugar won't begin to sweeten my tea or coffee, I don't feel afraid that a billlionth of a grain of anything would poison me—no, not if it were snake-venom; and if it were not disgusting, I would swallow a handful of his *lachesis* globules, to please my husband. But if I ever become a doctor's wife, my husband will not be one of that kind of practitioners, you may be sure of that, not an "eclectic," nor a "faith-cure" man.

Alas, that a woman entertaining such just sentiments in regard to medicine, should find her affinity in a clergyman, instead of in one of the graduates in medicine of Harvard.

SOCIETY PROCEEDINGS.

NEW YORK STATE MEDICAL ASSOCIATION.

Second Annual Meeting, held in the hall of the Murray Hill Hotel, New York, Nov. 17, 18, 19, and 20, 1885.

TUESDAY, NOVEMBER 17TH.—FIRST DAY.

AFTERNOON SESSION.

DR. HENRY D. DIDAMA read a paper on

TUBERCULAR CONSUMPTION; IS IT EVER HEREDITARY?

in which he quoted the opinions of different authorities on the subject of a hereditary tendency, hereditary diathesis, etc., and also the results of post-mortem exami-

Digitized by Google

nations by various pathologists, and said that in examinations of the bodies of thousands of fœtuses, none were found to have tubercle, which weighed heavily against the hereditary theory. He also quoted the statistics furnished by insurance companies, in which it appeared that the majority of cases of phthisis occurred in persons whose parents had not suffered from the disease.

The following are the conclusions which the author reached: First, that tubercular disease is not inherited. Second, that if a special tendency to the disease be transmitted, the term liability better expresses the idea than the term tendency. Third, many conditions, as poor and insufficient food, damp and impure air, stinted sunlight, and certain occupations, favor the development of the disease. Fourth, two conditions are almost indispensable—abundance of bacilli and an inviting asylum for their development, whether it be an inherited or an acquired vincibility.

An important indication is to place the newly born of a phthisical mother under the charge of a healthy wetnurse, who should occupy a room entirely secluded from that of the consumptive members of the family. This gives an opportunity to strengthen the feeble constitution and to eradicate a liability to the development of consumption. If a syphilitic taint exists or is suspected, the author advised antisyphilitic treatment, not only with a view to cure the syphilis, but also with a view to strengthen the constitution and guard against the development of phthisis.

DR. ROCHESTER said that some years ago he made an autopsy on an infant which died three weeks old, and he found one lung crammed with miliary tubercles, and in the other was a cavity the size of a hickorynut. The mother was healthy; the father had died before the baby was born. In another case in which the father died before the birth of the child, and the mother was a healthy woman, having no tuberculosis, the child died at eighteen months of age, having had for a long time before death every indication of pulmonary phthisis, and recently of tuberculosis of the vertebræ. In the light of these cases he could not help but believe that, sometimes at least, phthisis is hereditary. He admitted, however, that many people have phthisis whose parents were free from the disease. The paper was further discussed by Drs. Colvin, Pomeroy, and others.

DR. SIMEON TUCKER CLARK, of Niagara County, then presented a paper on

PSOITIS AND PERPSOITIS: THEIR PATHOLOGY AND DIFFERENTIAL DIAGNOSIS,

in which he first referred to the paucity of the literature of the subject, and the difficulties attending a differential diagnosis, and then proceeded to give the clinical histories of three cases which had come under his personal observation. In all of the three cases there was a history of traumatism. In the first case the patient, a woman without children, aged forty-three, had received a blow on the abdomen, which was followed by severe pain in the suprapubic region, two inches from the median line. The physician who examined her recognized a hard lump, from which the pain seemed to proceed. Vaginal examinaton resulted negatively. Dr. Clark saw the patient later, and became convinced that there was suppurative inflammation of the psoas. Finally, pus was removed, and thirty-one aspirations were made before a cure was finally effected. The pus did not contain a trace of phosphate of lime.

The second case was in a young man, whose condition originated in strains during roller skating. When he consulted his physician, Dr. Gould, he complained of pain in the region of the hip, and had a rapid, bounding pulse, the temperature 105°. Afterwards copious perspiration, of acid odor, etc., led to the diagnosis of rheumatism; but later a boggy tumor appeared in the suprapubic region. An exploratory puncture gave exit to foul gases, followed by pus. An opportunity to make an autopsy was afforded in this case, and a psoas abscess was found, which had led to denudation of the bone beneath; and there was also some softening of the vertebræ; but it was evident that the disease had originated in the muscle, and not in the vertebræ.

The third case was that of a man, who first attributed his difficulty to rheumatism, from which he was a frequent sufferer, but it was learned that he had injured himself in the region of the psoas while throwing filled sacks upon a wagon. He complained much of pain in the neighborhood of the thigh. The pain was relieved by a local anæsthetic. A suprapubic tumor developed, which, at a time when Dr. Clark had intended to open it, burst spontaneously into the bladder, and a quart of healthy pus was evacuated per urethram. Later, another opening for the escape of pus was made by the knife, above Poupart's ligament, and then pus ceased to escape through the bladder, and, finally, through the artificial opening, and the patient went on to complete recovery.

DR. CLARK pointed out, in the differential diagnosis, history of traumatism, pain in the region of the thigh and leg, the posture of the patient, avoiding extending and rotating the leg, the suprapubic tumor, and, on aspiration, obtaining laudable pus. In each instance the syringing of the pus cavity was followed by washing out with solution of carbolic acid.

DR. FREDERICK HYDE, of Portland, believed that many cases of supposed vertebral disease are really cases of the kind related by Dr. Clark, and he urged with great earnestness the importance of making a careful search in suspected cases for a history of traumatism, for a pelvic tumor, and for pus by repeated use of the aspirator, if necessary; for the train of evils following a change of the laudable pus, which was first present into unhealthful pus, is too long and serious to permit of postponement of the case, with the idea that eventually the symptoms will demonstrate it to be a case of Pott's disease. If taken in the early stage, a cure can be effected and the bones will escape implication.

DR. CRONYN, of Buffalo, had seen two or three cases of psoitis, and said that in diagnosis valuable aid will be found in putting the patient under the influence of chloroform, flexing the thigh, and searching for fluctuation over the region of the psoas muscle. History of traumatism is important in diagnosticating psoitis. Let the pus escape, then keep the leg in the extended position, bringing the walls of the sac together, and union will rapidly take place.

DR. MOORE, of Rochester, thought that where it can be shown that the disease has begun with a traumatism, it is unnecessary to try to explain its occurrence on the supposition of a tubercular inflammation. An acute disease may become chronic, and, of course, when this occurs, there is a good opportunity for tuberculosis to

Digitized by Google

develop. But the commencement may be in fibrous tissue, thence to the bone.

DR. CHARLES W. BROWN, of Elmira, then opened a discussion on

SHOCK, AND THE EFFECTS OF INJURIES UPON THE NERVOUS SYSTEM.

He described the symptoms present in shock, and referred briefly to the explanations which had been suggested of its nature. He had seen a few cases of what had been termed "insidious" shock, in which the patients did not suffer pain in proportion to the seriousness of the injury, and were of a cheerful state of mind, although there was almost a diagnostic melancholy expression upon the face, which seemed to foretell death. He also referred to individual susceptibility, and said that some persons of fleshy habit and apparent health will succumb sooner to a minor injury producing shock than some others of delicate habit and nervous temperament, the nervous system in the latter giving way less readily. Shock is less in persons suffering from chronic disease, but such persons are less likely to regain strength and make complete recovery afterwards, than are those of previous good health, who may be able to withstand the first influence of the injury upon the nervous system. There are two indications in treatment, the first to modify the effects of the shock, and the second to control superinflammation. The use of heat and stimulants received some attention.

DR. FRANK H. HAMILTON, of New York, continued the discussion with a short paper, read for him by Dr. Bermingham. His remarks were limited to surgical shock, which, he said, may be defined as a general paresis of the nervous system induced by external violence. One point which received his attention was what is called railroad shock. Many of the symptoms which have been described as belonging to railroad shock were seen in certain cases of shock which occurred before railroads had come into existence. But, if he admitted that the introduction of railroads had brought into existence a particular kind of shock, Dr. Hamilton thought it is due to that sort of injury to the spinal column which is likely to occur in railroad accidents, resembling the cracking of the lash of a whip. In these cases he believed that the injury is not primarily in the nature of a shock resulting from commotion of either peripheral or central nerves, but that those structures which lie external to the spinal marrow, and contribute more or less to its support and protection, of which the ligaments are the chief factors, are those which suffer direct injury, and from which inflammation subsequently progresses to the spinal marrow itself. As to the treatment of shock, bring about reaction by rest, in some cases by warmth and stumulants.

DR. EDMUND S. ARNOLD, of New York, took the view that shock is due to an impression produced upon the sympathetic nervous system, tending to stop its function, and in doing so stopping nutrition of vital parts over which that system of nerves presides. Sudden death occurs if such influence is sufficient entirely to destroy the function of this system of nerves or ganglia, as in death by lightning-stroke. Another illustration, he thought, is in death by hydrocyanic acid. If there is an influence upon the heart in this case, he thought it is directly due to suppressed function of the sympathetic system which presides over its action, and other parts of which system of nerves are also affected at the same time.

DR. CARLOS F. MACDONALD reported a case of

INSANITY FOLLOWING AN INJURY OF THE HEAD; CEREBRAL CYST; OPERATION; RECOVERY.

The patient was a man who received a pistolshot on the frontal region, inflicted by his own hand. The man was sent to prison, where he developed symptoms of insanity, and had to be confined to a cell. For a considerable period of time, however, he had been required, and was able, to do prison duty, but manifested an impassionate temper. It was decided to trephine. At the seat of the wound, which was half an inch in diameter, a fourth of an inch in depth, located over the right first frontal gyrus, corresponding to the junction of the anterior and middle third, three-eighths of an inch to the right of the median line. The patient was etherized. The wound was found traversed by dense fibrous tissue, no bone intervening between the dura mater. A fine hypodermatic needle was introduced, and nothing was withdrawn until the fourth puncture, when about two drachms of serum were withdrawn. The fluid contained a few blood corpuscles, which were accidental. Nothing more was done than to close wound with suture and dress antiseptically. The patient on coming from under the influence of the anæsthetic was in his natural mind, was greatly pleased with relief from pain at the seat of the injury, and shortly afterward gave a satisfactory account of his case from the beginning, excepting a period when he was unconscious. He went on to complete recovery, with permanent relief from cerebral symptoms, excepting a part of a day. It was learned that the physician who saw him after the shooting had removed the pistol-ball; he found no fracture of the bone, or spiculæ.

NIGHT SESSION.

DR. AUSTIN FLINT opened the

DISCUSSION OF PNEUMONIA

with a paper, in which he propounded the following eight questions:

1. Is acute lobar pneumonia a primary local inflammatory disease, or is it an essential fever, the pulmonary affection being secondary thereto and constituting its anatomical characteristic?

Since 1877, when he read a paper in support of the doctrine, that acute lobar pneumonia is not a local affection, but an essential fever, that doctrine has been gaining ground. This view is supported by the following facts: First. Acute lobar pneumonia is characterized by an enormous exudation into the pulmonary alveoli, and this exudation may be rapidly absorbed, leaving the tissues intact. This anatomical fact, he said, has no analogy in local disease. Second. Acute lobar pneumonia never persists and becomes a chronic affection. Third. It is never referable to any appreciable local condition, nor is it possible by any form of traumatic injury to produce the affection. Fourth. Ordinary causes of local disease are not capable of producing acute lobar pneumonia. The traditional belief that the affection may be produced by a cold is without foundation, and is being abandoned, even by the Germans. Fifth. That a special or specific influence is invariably the cause of

Digitized by Google

acute lobar pneumonia, is rendered probable by its occurrence at certain seasons, greater frequency in certain climates, occurrence at times as an epidemic disease. Sixth. It differs from acute primary local inflammation in that at the outset there is a pronounced chill. Seventh. In the course of the disease, the temperature and associated febrile phenomena bear no constant relation to the local affection. Eighth. Experience shows that acute lobar pneumonia responds better to treatment addressed to the fever, than to the local affection.

2. What facts and rational grounds, with our present knowledge, can be cited in support of the doctrine, that acute lobar pneumonia depends on the presence of a specific microörganism?

Dr. Flint left this question for discussion to Dr. Janeway, but expressed his belief in a specific microörganism as the cause of the disease.

3. What conditions or circumstances incident to acute lobar pneumonia, tend to render the disease fatal?

The present or previous existence of certain other diseases, renders the prognosis more unfavorable, and certain conditions, as empyema, pulmonary gangrene, malarial miasm, etc., are more likely to develop in one who has been reduced by pneumonia. Of special conditions rendering danger of a fatal issue in the course of the disease greatest, the author mentioned heart clot and heart failure.

4. Are there known remedies or therapeutic measures capable of arresting this disease, or of exerting a curative influence by either shortening its duration or conducing in any way to a favorable termination?

Dr. Flint had reason to believe, that quinia had been of benefit in shortening or exerting a favorable influence upon acute lobar pneumonia. But he could not enter fully into discussion of the treatment.

5. Is bloodletting ever indicated in this disease, and, if so, what are the circumstances indicating and contra-indicating this measure of treatment?

Acute lobar pneumonia tends intrinsically toward recovery. Treatment in general should be for special indications. He believed there are circumstances in which bloodletting will prove of benefit, and that benefit will be most likely to manifest itself in relief of oppressed heart-action. Contraindications of bloodletting are previous existence of enfeebling affections, and the anæmic state. A plethoric condition and a bounding pulse are among indications for this measure. The collection of cases made some years ago by Lewes, in which there were twenty-eight deaths out of a total of seventy-eight cases in which bloodletting was resorted to, showing a high mortality; but the cases were not selected.

6. Is alcohol useful in the treatment of cases of acute lobar pneumonia, and, if so, what are the indications for its use, and how is its use to be regulated as regards the quantity given, etc.?

The author regarded alcohol as indicated wherever there is required the supporting plan of treatment; wherever there is a tendency to asthenia, it should be begun tentatively.

7. To what extent is it safe and useful to employ antipyretic measures of treatment in cases of acute lobar pneumonia, inclusive of the cold bath, sponging of the body, or the wet sheet?

Dr. Flint spoke specially as to his experience with the wet sheet, which he had employed in three cases, with favorable results.

8. Do relapses of acute lobar pneumonia ever occur during or shortly after convalescence, and does this disease involve any special liability to other diseases, or sequels.

The first part of the question, the author answered in the negative, and said that this fact is in favor of the view that the disease is an essential fever, for local diseases have relapses. But one attack does not exempt against subsequent attacks.

The first question propounded was discussed in brief papers by Drs. Didama and Ross; the second by Dr. Janeway, who expressed regret at having been unable, on account of sickness, to make further investigations, personally, regarding the influence of a microörganism in the causation of pneumonia. He gave a synopsis of the literature of the subject. The third question was discussed by Drs. W. H. Robb and H. M. Biggs; the fourth by Drs. T. F. Rochester and Van de Warker; the fifth by Drs. S. J. Clark and C. S. Wood; the sixth by Drs. John Shrady and E. D. Ferguson; the seventh by Drs. G. Griswold, C. G. Stockton, and W. S. Fuller; the eighth by Dr. J. G. Orton.

WEDNESDAY, NOVEMBER 18TH.—SECOND DAY.

MORNING SESSION.

DISCUSSION ON PNEUMONIA.

DR. CHARLES G. STOCKTON discussed the seventh question propounded by Dr. Flint in a brief paper, and said he thought the special manner in which the temperature should be lowered would depend upon the individual case; a single antipyretic would not answer in all cases of elevation of the temperature. He had sometimes used quinine and antipyrin successfully in the same case. Regarding antipyrin, he recommended its use in from fifteen to twenty grain doses, repeated once in eight to twelve hours. When so used, it had never produced any toxic effects upon the heart, and it had had the desired effect upon the temperature.

DR. E. D. FERGUSON'S experience with antipyrin had been similar.

DR. J. G. ORTON discussed the eighth question in a brief paper. He had never seen an unqualified case of relapse of acute lobar pneumonia, during or shortly after the period of convalescence. But one attack seemed to predispose to subsequent ones in the same lobule. He thought pneumonia is a non-infectious essential fever. He also spoke of complications and diseases to which pneumonia predisposes.

DR. F. HYDE had in several cases found evidence at autopsies in cases of acute lobar pneumonia, that there had been early and persistent thrombosis as well as embolism of the veins, and in two cases there was embolism in the arteries as well. This condition, he thought, occurs more frequently than is supposed, and we could see why remedial measures proved of no avail, and why death occurred so early in the course of the disease.

DR. ELY VAN DE WARKER, of Syracuse, then read a paper on the

MEDICO-LEGAL BEARING OF PELVIC INJURIES IN WOMEN,

in which he said that actions at law to recover damages for injuries sustained to the pelvic organs in women

Digitized by Google

were becoming quite frequent and involved large sums of money; they were usually brought against corporations, particularly cities and villages, and railroad companies. He cited three illustrative cases, by which it appeared that the facts of the case, could they be obtained by a thorough medical examination, were in favor of the defendant, but the verdict was likely to be in favor of the complainant. Some of the women attributed conscientiously but erroneously their symptoms to the injury sustained, but most of the cases were of a fraudulent nature. In all perhaps there would be found a history of previous pelvic inflammation, or affections which would fully account for the symptoms present. The impossibility of a fall, of some nature, which was the usual accident in these cases, producing such concussion of the healthy uterus and pelvic organs as to cause permanent displacement of the womb, or swelling and pelvic inflammation and abscess, was evident to the physician but not to the simple juryman, whose sympathies were appealed to by a suffering woman standing before him, while the other party to the action was a heartless corporation with a supposed unlimited supply of money.

DR. AUSTIN FLINT, JR., then read an address on

SOME OF THE RELATIONS OF PHYSIOLOGY TO THE PRACTICE OF MEDICINE.

He said that physiology is the only rational basis of scientific medicine; this is true, even should we use the term medicine in its widest signification, including in it the practice of surgery, gynecology, and pathology. A knowledge of anatomy and physiology is a most important requisite in making a correct diagnosis. The necessity for a knowledge of physiology is evident in the study of valvular lesions of the heart, for our ability to diagnosticate heart lesions depends upon our familiarity with the functions of the heart and the sounds produced by the blood-current in health. Dr. Flint analyzed the heart sounds in different diseased conditions of the heart in proof of his assertion that a knowledge of physiology is an important element in scientific medicine.

AFTERNOON SESSION.

DR. ISAAC E. TAYLOR read a paper on

RECTO-LABIAL OR VULVAR FISTULÆ: THEIR CAUSES AND TREATMENT,

in which he spoke of the comparative rarity of the condition. It is very liable to begin with a vulvar abscess, depending upon an inflammation of the vulvar glands, perhaps excited by injury during coition, masturbation, labor, direct injury, or in cold. A small tumor may exist in the labia prior to breaking down into an abscess, perhaps quite movable, and leading to the suspicion of an ovary in Broca's canal. The history of such a case, seen by the author, was given. The tumor constituting the suspected ovary broke, and gases and feces escaped by the small opening. Huguier's plates were shown in illustration of the subject-matter of the paper. The pathognomonic symptom of vulvar fistulæ is the escape of air and thin feces. The vulvar opening is usually small—perhaps so small that it will be found with great difficulty. As to the treatment, he adopted the ligature, being in general the method employed by Barton between 1835 and 1840. The method is simple and efficient; and, in view of the great and serious difficulties liable to attend the use of the knife, he thought it deserves much more general employment. The elastic ligature is to be preferred.

DR. EDWARD M. MOORE then read a paper on

RECURRING LUXATIONS.

That luxations are likely to recur, he would not attempt to prove, for it is a well-known fact. Recurrence of the luxation takes place often not as a result of violence, but of the action of different forces not connected with violence. Some replacements are maintained with great difficulty. Attention was then called to the tendency of recurrence of luxation in different joints, and to the manner of preventing this accident. To prevent recurrence of luxation in the clavicle the elbow is thrown backward and retained in that position by binding the hand to the side by means of adhesive plaster, or, what is better, by means of his figure-S bandage; thus the scapula will be carried nearer the vertebral column.

Several interesting cases in which recurrence of luxation took place in the shoulder-joint were related, and the manner in which the accident is liable to occur was pointed out. His views with regard to luxations occurring in this joint were made clear by certain experiments which he had performed after removal of the flesh about the shoulder, and bringing forces applied upon the arm and forearm to bear upon the ligamentous structures. His experiments illustrated incidentally how it is that in many cases of sprains or supposed injury to ligamentous filaments, the symptoms are as serious and more prolonged than in fractures of bone; for, as was shown in these instances, the ligament gives way only by taking with it a portion of the bone to which it is attached. In luxations at the shoulder, either upon the dorsum of the scapula or into the axilla, examples are met with in which maintenance of reduction is found difficult. The manner in which the luxation takes place is by gravity—allowing the arm to fall, especially if at the same time the arm be turned more or less forcibly outward. Touching upon recurrence of luxation at the hip-joint, the author cited an interesting case which had come under his observation, and had been reported, with two others, by Bigelow, in which a soldier acquired the tact of dislocating and replacing the head of the femur by a certain twisting motion of the body.

DR. FREDERICK HYDE read a paper on

THE DIFFERENCE IN THE SYMPTOMS OF STRANGULATED OBLIQUE INGUINAL HERNIA,

in which the following were the principal points developed:

1. In proportion to the length of time an inguinal hernia existed would the symptoms and signs of strangulation be mild and chronic.

2. In a case of long-standing inguinal hernia in which signs of stricture of the bowel are obscure, there not being evidence of total obstruction of the canal, often it is not safe to wait for fecal regurgitation before deciding that strangulation exists.

3. When strangulation occurs at the first protrusion, the symptoms of strangulation will be found to be more marked.

Digitized by Google

4. If hiccough and fecal vomiting existed from nearly the beginning of the symptoms, no time is to be lost, herniotomy should be performed at once.

5. If a swelling exists with symptoms of obstruction of the bowel, the patient complaining of severe pain in the abdomen, but of none in the tumor, and had hiccough, although there is absence of marked general disturbance, a fair trial of taxis should be made, and that failing to reduce the tumor, herniotomy should not be delayed. This remark was based on an interesting case, the history of which Dr. Hyde gave in detail. No fecal vomiting occurred, no pain in the tumor even after taxis, but there was some pain in the abdomen and hiccough. Because of the mildness of the symptoms, the consulting physicians delayed the operation more than twelve days, and when it was finally performed the strangulation was found to have existed within the abdomen. The patient died.

6. If no strangulated portion be found within the external sac, the finger should be passed internally and adhesions sought for in the neighborhood of the opening.

7. Too long a trial of taxis before dividing a stricture should be guarded against, as it prepares the way for the death of the patient after herniotomy.

8. After stercoraceous vomiting has set in taxis should not be supplied, but herniotomy should be performed at once, although the prognosis is unfavorable.

9. If after opening the sac the omentum is found smooth, and no intestine can be detected, the omentum should be opened to learn whether it may not contain a strangulated portion of intestine. It is unfair to speak of herniotomy as a dangerous surgical operation *per se*. The danger attending the operation is due to the condition of the sac and its contents and to taxis and delay in operating.

DR. J. W. S. GOULEY read some notes on the same subject, in which he reached the following conclusions:

1. When doubt arises in the mind of the surgeon respecting the existence of strangulation of the intestine or omentum in case of incarcerated hernia, it is his duty to give the patient the benefit of the doubt by at once resorting to the operation of herniotomy.

2. Delay in relieving the strangulation is often fatal, while herniotomy in a case in which no strangulation exists is not usually harmful.

3. Medicinal treatment is often delusive, and local applications, such as opium, tobacco poultices, ice, etc., are in most cases worse than useless.

4. Persistent taxis is infinitely more dangerous than herniotomy, and such taxis even when it is followed by reduction of the hernial protrusion is often the cause of fatal peritonitis.

5. Another, though rare, effect of violent taxis is the reduction *en masse* of the hernia in its state of strangulation, and its result is known.

6. As a general rule, two minutes of gentle taxis, the patient being in a hot bath, will settle the question as to the possibility of safely reducing the hernia.

7. Therefore, it may be said with propriety that the less taxis, the less ice, the less other topical applications, the less opium, the less general or special meddlesome interference which often do serious injury to the intestine, the better the chances of recovery in the event of herniotomy. This is particularly the case in femoral hernia.

He said he had abstained from incising the neck of the sac in femoral hernia, but had made divulsion by simply insinuating the index-finger through the free opening made in the sac until it entered the abdominal cavity, and had had no trouble in effecting reduction of the intestine, the object of the procedure being to avoid division of the obturator artery should it be abnormally situated. He coincided with Dr. Hyde that hernia is not *per se* a dangerous operation. Dr. Gouley said further that if it seemed necessary in a case of inguinal hernia, after herniotomy, he would open the abdominal cavity in order to relieve the strangulated intestine.

NIGHT SESSION.

DR. ISAAC PURDY presented

A CURSORY REVIEW OF THE EPIDEMIC AND ENDEMIC DISEASES OF SULLIVAN COUNTY DURING THE LAST THIRTY-FOUR YEARS.

The first years of the period, commencing in 1850, pneumonia and fevers of asthenic type prevailed, in which it was common to bleed, to employ cathartics, diuretics, and a depleting system of treatment; and this course seemed to be indicated as being followed by the best results. About the beginning of 1854 typhoid fever was heard from in the distance, and soon reached Sullivan County, and for several years pneumonia and other forms of disease took on a typhoid character, and this period was marked by the fact that in nearly all cases the asthenic form of disease showed itself; a depletory course of treatment was followed by the worst results. Close attention had to be given to the diet, encouraging nutrition, and to checking excessive discharges. About 1860 diphtheria began to prevail in Delaware, and marched up the Delaware River, and existed in Sullivan County in the epidemic form for about five years, being very violent, and carrying away many patients. The odor of persons suffering from the disease was peculiar, and could be recognized at a great distance from the sick-bed. In the author's opinion, it was a constitutional, not local, affection, although the local deposit, constituting diphtheritic croup, was present.

About 1862–63 it was present in the form of black fever, petechial fever, etc., being in places very malignant. Afterward it again appeared as genuine diphtheria of the throat. In these cases they applied turpentine and sweet oil to the throat at night with benefit. During a part of this period dysentery prevailed, first severe, then of mild type. Scarlet fever was present at intervals of about five years, sometimes of severe, sometimes of mild character. Rubeola or measles had occurred at different periods, but in general required little treatment. Occasionally diphtheritic cases occur up to the present time, but the contagion was generally brought from afar. Typhoid fever continued to prevail more or less, especially in the fall months; typhoid pneumonia during the winter, up to 1881. The spread of typhoid fever up the Hudson and its tributaries occurred at one period. The highest point was situated 1200 feet above the level of the sea at Montauk. The treatment consisted chiefly in moving the bowels, particularly by calomel, and then genuine as a sheet-anchor.

(*To be concluded.*)

CINCINNATI ACADEMY OF MEDICINE.

Stated Meeting, November 16, 1885.

THE PRESIDENT, SAMUEL NICKELS, M.D., IN THE CHAIR.

(Specially reported for THE MEDICAL NEWS.)

DR. BERNARD TAUBER read a paper on

THE LOCAL TREATMENT OF LARYNGEAL TUBERCULOSIS.

(See page 596.)

DR. A. B. THRASHER gave expression to his disbelief in the ability of any plan to prolong life in cases of laryngeal phthisis. The instances in which a favorable result has been claimed for a certain plan of treatment, usually depend upon errors in diagnosis. With reference to the relation of the laryngeal affection to phthisis of the lungs, referred to without comment by the essayist, the speaker expressed the belief that the disease generally, if not always, commences within the chest, the affection of the larynx being in the same proportion a secondary disease. Prolonged expiration, as referred to, is the very earliest indication of the presence of disease in the lungs. It is further possible, in many of these cases, to effect a cure of the disease simply by proper hygienic treatment without the use of remedies. The local treatment, in these cases, is not of much importance with regard to the final result of the case, and in making a choice of remedies we should confine ourselves to those which will give the most complete temporary relief from suffering. Inhalations of carbolized steam have been employed with benefit, but, so far as the speaker was aware, the remedy had not been employed to so vigorous an extent as was recommended in the paper. The production of anæsthesia in the larynx in the second stage of tuberculosis is of great importance. A number of agents have been employed for this purpose. Dr. Carl Seiler claims to relieve the pain by the local application of the nitrate of silver. If employed, the remedy must of course be used in concentrated solutions, because of the painful effects otherwise produced. In the treatment of the third stage he agreed with the authors who recommend the use of morphia by insufflation combined with starch powder. This method should not, however, be practised within a shorter interval than an hour before a meal, for it requires fully an hour to obtain the full effect of the remedy. The relief afforded by it is only transient, it is true, but the method has the advantage of being easy of application, not requiring the skill of a specialist, or indeed of the physician.

The opinion that tuberculosis, when found in the larynx, is always a secondary affection, the speaker believed is further demonstrated by the fact that no post-mortem examinations have yet been conducted upon persons dying with laryngeal phthisis, in which the affection had been positively diagnosticated during life, where the disease was not found also in the lung.

DR. JAMES G. HYNDMAN remarked that the hopes offered us by the essayist of being able to cure a disease whose prognosis is almost universally fatal, would be very cheering, did not the combined and uniform experience of the leading specialists of the world prove them fallacious.

Mackenzie knows of but four cases in which he had reason to believe a cure was affected, and these cases were proven to be tubercular by the presence of well-marked signs of pulmonary disease. While not denying the possibility of tuberculosis primarily affecting the larynx, the speaker thought it quite improbable in view of our present knowledge upon this subject, and quoted the results of Heinze's numerous observations to the effect, that no post-mortem examination had ever been made in a case of laryngeal phthisis which did not show well-marked evidences of the disease of the lung, and the pulmonary affection appeared in all those cases under his observation to have been well advanced. In the earlier stages of laryngeal tuberculosis, the local appearances are such as may result from numerous conditions causing malnutrition, and it is only their association with distinct evidence of pulmonary damage which renders positive a diagnosis of laryngeal phthisis. The cures effected by the essayist were of cases in the earlier stage, and it is much to be regretted that the reporter gave no positive statement of the condition of the lungs, for it is in just these cases we most require the corroborative evidence of pulmonary disease and thus be able to exclude all danger of mistaking the cure of a trivial, for one of a very dangerous malady. The speaker agreed in the main with the essayist's plans of local treatment, but believed that it must be mainly palliative and that our efforts must be principally directed to the primary disease in the lungs and the general weakness resulting from the combined pulmonary and laryngeal affections.

DR. E. G. ZENKE thought it erroneous to consider phthisis of the larynx only a secondary affection. M. Jaccoud, among others, advocates the doctrine that phthisis can be cured if properly treated. Whether or not the bacillus is the cause of the disease, is of little practical bearing upon the treatment, so far as we know at the present time. If the disease can be removed from the lungs, it should certainly be more easily eradicated from the larynx; and a man's skill in the treatment of the disease will consist in his ability to apply proper remedies to the larynx.

DR. JAMES M. FRENCH expressed his preference for the term tuberculosis instead of the word phthisis, which appeared to be the favorite with the speakers of the evening. The former term is more in accord with modern nomenclature, as well as with the more recent views on the pathology of the affection. For we now look upon the disease as one having a special dependence upon a definite microörganism, and not simply as a destructive process. He further objected, *a priori*, to the view that laryngeal tuberculosis is always a secondary affection. If the disease owes its origin to a germ, we can readily understand how it may be produced in the mucous membrane of the larynx as readily as in that of the smaller bronchi, and there is no more reason for pronouncing the affection secondary when found in the larynx than when found in any other tissue of the body, where it is of frequent occurrence. It is only when an early stage of the affection is observed in the larynx, in connection with a more advanced invasion of the lung, that it should be pronounced secondary. If, however, the disease of the larynx is advanced, and that in the lung is indicated by only such signs as a slight prolongation of expiration, in-

Digitized by Google

crease of vocal or whispered resonance, or a faint crepitation in some part of the lungs, all recognized as among the earliest manifestations, we may with propriety consider the pulmonary lesions secondary to the laryngeal, or simply coincident to them.

With reference to the local treatment, the experience of the speaker did not warrant his expression of an opinion. But as it is always advisable to combine with the local treatment some course of general medication, he desired to express his confidence in the administration of the bichloride of mercury in combination with the sulphate of strychnine, from which he had in several instances obtained unquestionably good results, in both the early and median stages of the disease.

DR. HYNDMAN said that it is an easy matter for one to state his inability to understand why a lesion is or is not primary in a certain organ, but that so long as statistics do not coincide with the view, it can have little bearing on the result. The statistics to which he had just called attention were to his mind sufficient to indicate that the occurrence of primary tuberculosis of the larynx is exceedingly rare. He desired also to call attention to the use of morphia, dissolved in glycerine and water, as a local application to the larynx. The glycerine renders the effect more lasting by retaining the remedy longer in contact with the mucous membrane.

DR. ZENKE remarked that in all probability the reason for not finding tuberculosis unassociated with the pulmonary affection upon post-mortem examination, lay in the fact that tuberculosis of the larynx is rarely a fatal disease; and although it may exist for years, the death is usually the result of lesions elsewhere, independent, it may be, of the laryngeal affection.

DR. JOSEPH RANSOHOFF was gratified to hear one of the speakers support the ground that laryngeal tuberculosis is not of necessity a secondary affection. That such a position is tenable, he firmly believed. Only a few weeks ago he was consulted by another physician with regard to the propriety of operative measures, whether it should be to open the larynx and remove a tubercular depbsit, or totally extirpate the organ. The disease was very advanced and progressive in character, but the most thorough examination of the lungs failed to reveal the presence of any pulmonary disease. That the disease was not one of syphilis of the larynx, was well established by the fact that it had been examined by several gentlemen of skill, among them the speaker of the evening, and by each pronounced unmistakably tubercular in character. The disease, when seen by the speaker, had progressed to the extent of destructiveness, producing dysphagia, and even stenosis.

With reference to the statistics that have been quoted, the speaker said that while it is perfectly proper that we should be guided to a certain extent by the views of such men as Morell Mackenzie, it is yet highly probable that within the course of five years their views will undergo considerable modification. Their views have been derived from clinical experience, but at present there is a tendency to disregard clinical experience for a more scientific view of disease. We have tubercular disease in nearly all other parts of the body, including the skin, tongue, pharynx, tonsil—and why not in the larynx? And what is of still more value, a number of primary causes have been recently reported.

DR. ROBERT W. STEWART reported a case of tubercular disease of the larynx without other discernible lesions, in which recovery followed the patient's removal to more healthy climates—Florida in winter and Colorado in summer. The speaker thought it a matter of little importance whether phthisis is tuberculous or not, and in some cases he was inclined to doubt their identity. Further it does not necessarily follow that, where tuberculosis of the larynx is found associated with advanced tuberculosis of the lung, the disease commenced in the latter organ. There is sufficient ground for considering phthisis sometimes of primary origin in the larynx.

DR. TAUBER, in closing the discussion, called attention to the fact that in his paper he had not quoted an authority. He had desired to express only his own experience. In a review of the literature of the subject he had found eight cases of primary tubercular infection of the larynx, but this was a question which he had no intention of raising by his paper.

With reference to the anæmic stage of laryngeal tuberculosis, he agreed with the speaker who stated that such an appearance may be associated with a number of other conditions, but when it is associated with the inactivity of the larynx and a relaxed condition of the cords, with the various subjective symptoms usually seen, it is almost pathognomonic of the disease. As for the use of the nitrate of silver, he had employed it in solutions of varying strength, up to 140 grains to the fluidounce, but had found its effect not to be sufficiently lasting. The point he desired to lay most stress upon is the treatment of the third stage of the affection by the method he had described. It enables the patient to eat and thus to retain his strength, in this manner prolonging his life.

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, November 3, 1885.

THE PRESIDENT, W. P. BIRDSALL, M.D., IN THE CHAIR.

DR. LEONARD WEBER read a paper on

A CASE OF OPHTHALMOPLEGIA EXTERNA.

Peter W., æt. 52, father of a number of apparently healthy children. Has worked in an iron foundry for the last thirty-two years. His mother died of pulmonary hemorrhage at 64 years of age; his father died at 53 of typhoid fever. Has a brother and sister living, in good health. He has never had syphilis. Fourteen years ago he was under treatment for hæmoptysis, accompanied by fever and other signs of acute lung trouble. But he recovered in the course of a year or so, and has been able to continue his work since. Nevertheless, the signs of old pulmonary trouble are well marked in the interscapular space, particularly on the right side. In the course of years the patient sustained various injuries about the head, but no fracture of the skull. At no time did his condition give any evidence of renal or cardiac disease. Since February 1, 1885, he experienced considerable and lasting pain at the back of the head on the right side. In getting out of bed on the morning of February 23, of the present year, he felt somewhat dizzy, and noticed a pain in the right temporal, extending to the occipital, region. He also found that he could not use his eyes as on the night before. He continued to

Digitized by Google

work, however, and on March 9, 1885, consulted Dr. Mittendorf, who reports that the use of the patient's right eye was lost early in childhood. The left eye gave him no trouble until recently. On March 9th both eyes were found to have turned considerably toward the nose. Neither eye can be moved in the direction of the external rectus. The pupils slightly contracted, accommodation good. Treatment: Hypermetropia necessitating use of strong glass for left eye to make reading possible. Vision of right eye, which has a corneal macula, very poor. Acuity of vision of the left eye (not fairly tested, patient presenting himself at night) about 20 or 30. Marked hyperæmia of the left disk. Interior of eyes normal. Paralysis extended to third nerve, but was not complete. Patient would move his eyes downward considerably at times, but he seemed to have lost control over the movements of the muscles, and if directed to look in a certain direction, he could not not do it. On March 1st he first noticed some numbness and a cold feeling from the fingers up to the middle of the arm on the right side. While this sensation was unpleasant, it in no way interfered with his work of using a heavy hammer, but about April 15th his arm became weak. At the same time coördinate muscular action became impaired. He was unable to direct blows with precision, often striking an inch to either side of the object. He soon had to quit work.

He consulted me on May 14th. At that time the eyeballs were almost immovably fixed. Nevertheless there was complete paralysis of the external recti only. The levatores palpebrarum were not affected, neither were the muscles of the iris. The right hand was colder than the left. Sense of touch diminished, actual muscular power also. Visible trembling and gradual dropping of wrist when the extremity is extended horizontally, showing weakness of extensors. Slight exaggeration of patellar tendon reflex on right side.

The patient's speech was not very articulate; some dysæsthesia existed already. There was no dysphagia, and no symptom indicating disturbance of cerebral nerves other than of the fifth pair. The gait was unsteady, resembling that described by Nothnagel in connection with certain cerebellar affections. The lesion producing the above symptoms I am inclined to locate in the pons. As to its nature, it is probably a neoplasm of syphilitic or tubercular origin.

The patient was ordered iodide of potassium in doses beginning with ten grains three times a day, which was increased by five grains every week. In this way the dose was carried up to forty grains three times a day. From June on, a noticeable improvement began, and by September 2d his speech had become almost normal. The power of his right arm was much increased, there was no more headache, and the eyes had largely recovered their mobility.

On October 30th it was observed that the eyes could be freely moved, although some paresis of the external recti still remained. The patient was then taking forty-five grains of the iodide three times a day. Some spitting of blood now occurring, the remedy was discontinued for two weeks, and then resumed with an initial dose of twenty grains.

I believe the anatomical lesion to be situated in the left half of the pons, near the tegmentum, involving the lemniscus, and extending beyond the raphe, some little distance into the right half of it.

DR. W. M. MITTENDORF said the author of the paper was to be congratulated on the result of the treatment in this interesting case. As stated in the paper, when the patient visited him, there was this paralysis of the external recti, and he thought there was also a slight defect of the facial nerve, and he was inclined to place the lesion in the upper part of the fourth ventricle, but, as motor oculi paralysis developed, he came to the conclusion that there was a more extensive lesion than he had at first supposed. An interesting feature in the case was the fact that, while there was ophthalmoplegia externa, there was at no time while the patient was under his care, any affection of the intrinsic muscles, and this fact, according to recent investigations, pointed to a lesion below the aqueduct of Sylvius. The cases of ophthalmoplegia externa without other symptoms, were very few. He had now under his care a young man with ophthalmoplegia affecting both eyes, in whom there had been no change for two years. The lesion, he supposed, was to be placed in the region of the corpora quadrigemina. At one time he thought there were real ataxic symptoms, but he was unable to make out a clear case of locomotor ataxia.

DR. T. R. POOLEY thought the fact that the patient struck to the outer side of the body, which had been attributed by the author to paresis, might have been caused by faulty projection depending upon paresis of the external rectus muscle. He had never seen a case of complete paralysis of the ocular muscles with so satisfactory results.

DR. WEBER remarked that at first there was no tendency to strike outward. In reply to a question by Dr. Spitzka, he said there had been no wasting of the muscles, although the general nutrition of the patient had not been at all times equally good.

THE PRESIDENT had reported two cases to the American Neurological Society, which in some respects resembled this case, but in some other respects there were important differences. He reported them as cases of ophthalmoplegia externa, according to Hutchinson's nomenclature, and they were, strictly speaking, cases of this sort. The ciliary muscle and the iris were not involved at any time, while the external muscles of both eyes were involved to a greater or less degree. No other nerve tract in the body could be found defective. The two cases had remained about in the same condition, with slight improvement, for two years. It seemed to him, however, that the cases which Hutchinson had reported under the name ophthalmoplegia externa did not all belong to that class, for in only two or three were the external muscles of the eye alone affected. Most of his cases were of a complex character. It seemed to him that the pathology of these cases must vary greatly. The lesion would probably be found to vary, not only in location, but also in character. His cases, he thought, were due to a slow degenerative form of disease, similar to that in progressive muscular atrophy. Certainly some of Hutchinson's cases were of a multiple character, and probably in many others the lesions were multiple.

DR. E. C. SPITZKA was much pleased to find a doubtful point in the past history of the case cleared up by

Digitized by Google

Dr. Pooley's discovery of a residual paresis of the other rectus externus. It adds, however, to the difficulties of localization, though not incompatible with the diagnosis of Dr. Weber. With regard to Dr. Pooley's suggestion, that the loss of skilled motion of the right side is due to the eye trouble, that possibility had already been taken into account, and disposed of for the following reasons: First, the motor disturbance was not present when the eye trouble was at its height, nor present when the latter began. He believed ophthalmologists will agree that locomotor trouble is apt to be proportionate to the intensity of the eye complaint, and, if anything, to be regulated, provided the eye trouble remains stationary or improves. In this instance, however, we have eye trouble at its maximum without arm trouble, and arm trouble developing as the eye trouble improves, and manifested when the eyes are closed. Besides, we must bear in mind that, as the patient has not had the use of his right eye from childhood, he would not be as likely to be disturbed in his movements as patients with binocular vision would be. He believed the oculo-motor disturbance can be best accounted for by a regional extension of lesion in that part of the tegmentum which lies between the trochlearis and abducens nuclei, and where certain coördinating tracts run.

DR. WEBER asked Dr. Mittendorf whether there were not for a time symptoms of hemianopsia.

DR. MITTENDORF said that there was no lesion of the retina or nerve when he examined the patient.

DR. M. A. STARR asked whether there had been any ptosis.

DR. WEBER replied in the negative.

DR. STARR thought that a lesion lying outside of the cerebral axis, as a syphilitic meningitis, affecting the adducens nerves at their exit between the medulla and pons, might explain the symptoms more intelligibly, than to suppose a lesion in the floor of the fourth ventricle affecting the nuclei themselves. Of course, such a lesion would yield to syphilitic treatment, whereas he could not conceive of a nerve nucleus' being destroyed and again restored. If the third nerve were involved, he might suppose the meningitis had extended a little further forward. He had the privilege of seeing a case in Baumberger's wards at Vienna three years ago, in which the third, the fourth, the sixth, the seventh, and the eighth nerves upon one side were paralyzed, and Baumberger made the diagnosis of lesion at the floor of the fourth ventricle, involving the nerve nuclei from above downward, especially so as there were signs of atrophy in the facial muscles. The autopsy showed localized meningitis affecting these nerve trunks after their exit from the cerebral axis.

DR. WEBER again mentioned the symptoms present, and said that, so far as the oculo-motorius was concerned, there certainly was an affection of the superior and inferior recti.

DR. E. C. SEGUIN had not been convinced, from seeing the patient this evening, that there were any ataxic symptoms in the right upper extremity. The dropping of the fingers might indicate either weakness of the extensors or the loss of a certain amount of muscular sense, which might be due to a lesion situated in many places besides the pons. He was inclined to Dr. Starr's view. The discussion seemed to indicate the vanity of theoretical pathology.

DR. SPITZKA, in a crude way, had always regarded muscular sense disturbance as a factor of ataxia, and he believed authorities generally would so consider it.

DR. SEGUIN said that Erb recently described a case in which there was ataxia, but all kinds of sensation were perfect.

DR. SPITZKA replied that that had nothing to do with the question. Ataxia is of different kinds, cerebellar, spinal, due to ordinary contact, to muscle sense, space sense, and coördinary disturbances, sometimes singly, sometimes combined; but muscular sense disturbance is mentioned in the definitions of ataxia by our best authorities, and he should like Dr. Seguin or any one to formulate a general definition of ataxia which should declare muscular sense disturbance not to be a factor. It is precisely because there is muscular sense disturbance that he believes the lesion to be one of the pons. The interolivary layer happens to run in the deep part of pons. In those levels where the cranial nerve symptoms of this case are possible, he had shown, if any one case be conclusive, that this layer is the muscular sense tract, and the case agrees with others of its kind. There is a combination of slight paresis with the muscular sense disturbance which is almost characteristic of certain pons diseases—it requiring but an extension of the lesion across the deep transverse pons fibres to involve the pyramidal tract bundles. With regard to the suggestion of a meningitis, it does not seem to him to harmonize either theoretically or with experience. It is true that the affection of both abducent nerves might be accounted for in this way. But there are other symptoms which the supposed lesion must accommodate. How to account for the arm symptoms on this ground. he did not know. There are too many important nerves near the hypoglossal, whose function is intact, to account for the dysæsthesia on the ground of meningitis. Besides, there is no true paresis of the hypoglossal. Its intrinsic movements are well executed, and there is no evidence of either nuclear or peripheral hypoglossal palsy—in other words, it is some higher tract, the speech tract, that is involved—we know that this runs somewhere in the pons—near the raphe, whereby another nerve, the fifth, is affected in its decussation, thus accounting for the bilateral disturbance of face sensation. But the strongest objection to the meningitis theory is that it would have us believe it possible that the third pair can be diseased so totally in its extracerebral course or intracerebral course, for that matter, as to cause total paralysis of ocular motion, without any affection of the pupil, the accommodation, or the levator palpebræ. He has never heard of such a case, and does not think there is one reported, and he does believe such a case possible. If there were no other reasons for suspecting pons disease, it would, in his opinion, be confirmed by the character of the ocular paralysis; but, in addition, we have the almost pathognomonic combination of paresis and ataxia. True, Dr. Seguin calls it muscular sense disturbance, which it is undoubtedly—with this difference of interpretation and definition, that he says it is not ataxia, and Dr. Spitzka considered it to be such.

DR. STARR thought that the abducens nuclei could not be involved, together with the interolivary layer, without affecting the formatio reticularis, which ought to show sensory symptoms if affected.

DR. SPITZKA said that the difficulty seemed to be that

Digitized by Google

Dr. Starr had only one particular level of the pons in mind, one not necessary involved in this case. Even allowing the lesion to be in the level spoken of by Dr. Starr, the difficulty he discovers does not seem to him to be as he states it. That no symptoms referable to the formatio reticularis are present, can constitute no objection, as long as the function of that part which lies between the raphe and the abducens roots is unknown. The abducens roots, however, skirt and partly perforate the interolivary layer, and so far it is possible to have coincident abducens and muscular sense disturbance; the real difficulty in this case is to account for the double involvement of the abducens, without the bilateral involvement of the interolivary layer. As he understood Dr. Weber when he presented the case, he supposed the lesion to be in the anterior third of the pons, with a dorso-mesal, and possibly caudal, extension too near the ventricular floor. Here the altitude of the tegmentum is extremely low, a comparatively small lesion may involve the interolivary division of the lemniscus—he meant its continuation, the raphe, with its trigeminal decussation, the posterior longitudinal fasciculi, the pyramidal tract slightly, and the speech, either after Raymond and Artaug, or the other theories. The advantage of this explanation over the others offered is, that it requires the smallest lesion to harmonize with the symptoms, while grave objections can be urged against every other location, particularly the one which would locate the lesion as a meningitis involving peripheral nerves.

He reiterated that till the inconsistencies of the oculomotor paralysis are explained away, insuperable obstacles oppose the meningitis theory. Possibly Dr. Weber's reference to the voluntary control of single ocular muscles might lead to misapprehension. No ocular muscle is capable of isolated movement under voluntary effort, but groups of such are. There is a ready-made coördinated mechanism of which the posterior fasciculus is probably the important mediator, which regulates the coördination of both globes, and it is here where the trouble lies.

DR. LEONARD WEBER then read a paper entitled

A CONTRIBUTION TO THE STUDY OF LANDRY'S ASCENDING PARALYSIS.

It was in 1859 that Landry described a few cases of ascending paraplegia with negative post-mortem results as regarded the spinal cord, to which he gave the name of "paralysie ascendante aigue," and in the same year Kussmaul reported two rapidly fatal cases of paralysis in which the post-mortem appearance of the cord was apparently normal. The attempt of Petit fils to classify Landry's ascending paralysis among the varieties of poliomyelitis anterior acuta or subacuta, has been repeated quite recently by Prof. Immermann, but in the light of later researches and of negative results of autopsies made by Westphal, his theory is hardly tenable. Another and perhaps less objectionable theory is that of Rogers, who believes that many cases of the favorable form of Landry's paralysis are really polyneuritis acuta, of infectious or other origin, in which the spinal cord is either not at all or only secondarily affected. In an article in *L'Encephale*, No. 2, 1885, this writer instances the clinical picture presented in many affections of the spinal nerves, particularly in polyneuritis, in which the symptoms are very similar to those of disease of the medulla spinalis. In cases of simultaneous peripheral and spinal affection a correct diagnosis is of course difficult, but although we have hitherto, says Rogers, paid almost exclusive attention to the central lesions, the course of the disease often bears evidence of the fact that the lesion ascended from the periphery to the centre, and he claims that not only do many cases of Landry's paralysis belong in the category of peripheral nervous affections, but also Duchenne's "paralysie générale spinale subaigue," and "paralysie diffuse."

Dr. Weber then gave Rogers's description of the usual course of the disease, and said regarding the etiology that we were still in the dark; Westphal laid much stress upon infection, and Roger drew attention to the frequent coincidence of polyneuritis and tuberculosis. Erb said as late as 1879, that cases of progressive polyneuritis ought not to be mistaken for acute ascending paralysis, since the differential diagnosis is sufficiently established by the sharp pains, anæsthesia, and paralysis, limited to the affected nerves, and their rapid loss of electrical excitability.

On the strength of these recent observations, he thought it might be justifiable to speak of two forms of acute ascending paralysis—the well-characterized spinal and the less well-known peripheral. Acute ascending spinal paralysis is characterized clinically by motor paralysis, beginning usually in the lower extremities and advancing with some rapidity to the trunk and upper extremities. The bladder and rectum are but little affected; sensation is nearly normal, and the affected muscles do not waste much, or suffer any change in their electrical excitability. More or less fever may be present, and death from asphyxia is a not very unusual termination. No cord lesions are found at the autopsy. Landry's paralysis is more common in men than in women, and occurs with greatest frequency between the ages of twenty and forty years. It is thought by Landry, Westphal, Roger, and others, that infection, of an unknown character as yet, may be the real determining cause of the disease, and it is significant to note, that in some carefully made autopsies, changes similar to those occurring in other infectious diseases have been found in the liver, spleen, lymphatic glands, and intestinal follicles. In the fatal cases death may occur at a period of the disease varying from two or three days, to three or four weeks. But the average duration seems to be from eight to twelve days. When recovery ensues improvement begins usually within a few days after the disease has been fully developed, restoration occurring first in the parts last affected, and progressing very slowly.

Some cases of poliomyelitis anterior subacuta simulate very closely acute ascending paralysis, and it may not be until the development of atrophy and the loss of electrical excitability that we can be certain of the presence of anatomical lesions in the spinal cord. But a well-marked case of poliomyelitis anterior acuta is not progressive, does not attack the medulla oblongata nor lead directly to a fatal termination; the loss of faradic excitability and the muscular atrophy develop rapidly. In very light cases a doubt might arise in diagnosis. In acute general and infectious myelitis we always find fever, marked sensory disturbances, early loss of all the reflexes, paralysis of the sphincter, diminished faradic

Digitized by Google

excitability, bedsores, and a rapidly fatal termination, Certain forms of spinal syphilis resemble closely Landry's paralysis, and the diagnosis can often be determined only by the history of the case and the positive results of specific treatment. The prognosis of acute ascending paralysis is always serious, as it is impossible to tell at the beginning whether a case will result in recovery or death. Antisyphilitic treatment has given doubtful results, but better have been obtained from the wet pack or warm baths followed by cold affusions. Of remedies the best would seem to be iodide of potassium and ergot. The application of a continuous current along the spine is recommended by Erb.

The author then related the following case, which had been observed by himself: On December 20, 1880, he was called to see J. H., a butcher, thirty-one years of age, of apparently good constitution, no hereditary taint, syphilis denied. In early life he suffered often from intermittent fever. At the age of twenty-one he went to work in a barometer factory, and after some time began to grow weak, had occasional slight tremor. and frequent vertigo, but no salivation or other sign of mercurial poisoning. These troubles increased, so that he was compelled to give up his work after four years. He then spent four years in the West, and returned home in good health two years ago. About three weeks before he was seen by Dr. Weber, the patient's horse ran away with him in his open cart, and he was obliged to exert all of his strength to control the animal. He received no concussion or apparent injury, but felt tired and ill all the afternoon. The next day he kept about with difficulty, and the day following felt somewhat ill, and had slight fever; and, after some days of paræsthetic feelings, such as numbness and tingling creeping up from the fingers, he gradually lost the use of both arms; and two weeks later, after similar sensations proceeding from the toes upward, the lower extremities became also paraplegic. No paresis of the sphincters was noticed then or at any subsequent time. The stools were retarded. The intercostals and other muscles of the trunk remained intact, and there were no symptoms indicating involvement of the medulla oblongata, but the patient felt some pain along the spine, and continued to have pain and numbness here and there in the extremities.

Up to the time of Dr. Weber's visit the case had not been examined with special care. The author found the patient still unable to do more than move his limbs slightly while in bed; he could neither stand nor walk, nor had he the power to grasp firmly any object. Cutaneous sensation appeared to be normal, but the patellar and tendo Achillis reflexes were absent. The limbs were not wasted, and the muscles responded to electrical stimulus. Pulse and temperature were normal, and examination of the urine gave negative results. The slight improvement of the paralysis, noticeable to the patient at the beginning of the fourth week, had not progressed any further. Ascending myelitis and poliomyelitis were excluded, and the diagnosis made of ascending paralysis, Landry's. It being impossible to carry out at his home a systematic course of electrical treatment, with massage and warm baths, which seemed to be indicated, the patient was removed to Roosevelt Hospital, where the late Dr. Goetyky became interested in the case. He agreed with Dr. Weber as to the probably nature of the disease, and also looked upon the chances of recovery as good. The paitent was discharged cured on the thirtieth day, and was soon able to resume his occupation. He called at Dr. Weber's office October 30, 1885, at which time he appeared in fair health, could walk briskly and firmly, and said he was well able to attend to his business, but he required more sleep than he did five or six years ago. He had occasional backache, but no lancinating pains; the bowels were somewhat constipated; the urine normal; the patellar tendon reflex was totally abolished on both sides, and the patient could not stand very well on one foot when the eyes were closed. The pupils were normal. There were no sensory disturbances, and no paræsthesia.

The author then related briefly two cases recently reported by Sorgenfrey and H. Mietks, in which there was early loss of the patellar and tendo Achillis reflexes, but in which, as opposed to his own case, the reflexes returned after the complete recovery of the patients. He also mentioned a case of Immermann's, in which the diagnosis wavered between anterior poliomyelitis and Landry's paralysis, and in which, at the autopsy, there was found recent inflammation of the anterior horns in the cervical, dorsal, and lumbar regions of the cord. It was this case which led Immermann to conclude with Petit fils that both these clinical pictures might be due to the same morbid process, differing only in degree.

DR. E. C. SEGUIN had not seen a case of Landry's disease, but he had always had a strong suspicion that there was great similarity if not identity between that disease and poliomyelitis acuta. The mere matter of ascension did not seem to him to be of so great importance in the diagnosis. The views which, when a pupil, he had heard Brown-Séquard frequently express with regard to ascension of spinal symptoms had always seemed to him very reasonable. They were that ascension of symptoms might be apparent when they did not represent any ascending lesion in the cord; they were due to a change in the depth of the lesion in the cord. Suppose, theoretically, a case of paralysis of the arms, with later paralysis of the legs; it is not at all necessary to suppose a descending lesion in order to explain the descending symptoms; a change in the depth of a lesion which extends but a little ways up and down the cord will account for the descent of the symptoms. In the same way we could account for ascending symptoms without supposing an ascending lesion in the cord. Many authors lay stress upon the value of negative symptoms in the diagnosis of Landry's paralysis—such as absence of degenerative reaction and muscular atrophy; but it is equally true that in many cases of poliomyelitis these symptoms are retarded. He regarded Immermann's case as instructive, inasmuch as it shows the similarity if not the identity of the two diseases; the difference may be in exact location or in the virulence of the affection.

DR. PECKHAM described the symptoms in the case of a girl sixteen years of age, whom he saw only once, and made a diagnosis of acute poliomyelitis, following exposure by sitting on a rock at a picnic. He gave a favorable prognosis. The case was reported by Dr. Rockwell before the American Neurological Society, in June last, as one of transverse myelitis, with recovery. Con-

Digitized by Google

siderable discussion followed with regard to the nature of the disease.

DR. SACHS thought that while Immermann might entertain the idea that the pathological process in Landry's disease and poliomyelitis is the same, he did not suppose that he believes the lesions to be identical in localization. While the question of infectious origin has not been demonstrated in either acute myelitis or Landry's disease, Dr. Sach's thought it deserved investigation.

DR. WEBER closed the discussion, reviewing the differential diagnosis between Landry's paralysis and poliomyelitis anterior acuta.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, November 10, 1885.

THE PRESIDENT, ROBERT F. WEIR, M.D., IN THE CHAIR.

DR. L. M. YALE read a paper entitled

REMARKS ON EXCISION OF THE HIP.

(See page 592.)

DR. MARKOE said that the paper was so statistical in character that there was hardly room for discussion, and that it contained extremely interesting and very valuable accumulation of results obtained by different operators. So far as he had been able to discover, nothing appeared in the paper which indicated that the danger of tubercular infection was either greater or less in those operated upon than in those not operated upon.

DR. YALE said that was the conclusion, except in this one instance. Caumont analyzed all the cases treated in every way, between one and two hundred in all, and drew the conclusion that tuberculosis in no way is relieved by exsection; indeed, one-third died after excision, and one-fifth of his suppurative cases without exsection. Of course, that was not a sufficient large number of cases to settle the question.

THE PRESIDENT asked whether we are not premature in laying much stress on general infection after an operation upon a tuberculous bone or joint, as it was a matter which had not been brought to our notice, especially with reference to later pathological developments, until within the last two or three years. He should feel unwilling to accept such statements as conclusive until a larger experience had been obtained. This inference, if received as final, would cut off all attempts at operative interference for the purpose of getting ahead of tuberculous disease in bones and joints, and would render operative interference unjustifiable.

DR. C. T. POORE thought that private statistics should not be put in comparison with hospital statistics, because statistics derived from patients among the better classes are more favorable with regard to the expectant plan of treatment. He did not believe that statistics in general of excision of the hip-joint in hospital cases would show more than thirty-three per cent. mortality, and in the same class of children treated expectantly without operation, his impression was that mortality is greater than after excision.

He was unable to see, while persistent suppuration exists, how one can determine whether or not he had to deal with simple caries of the joint, or with a sequestrum which cannot be removed until an operation is performed. Besides, it is a serious question whether many cases of extensive disease of the acetabulum can ever get well without an operation, and whether an operation in those cases will remove that source of danger.

DR. F. LANGE thought it generally conceded that a comparatively large percentage of cases of hip-joint disease would entirely recover under proper conservative treatment, without excision of the joint. Even extensive destruction of bone does not exclude spontaneous recovery and comparatively good functional result. He has observed so much destruction of bone, that, at last, the trochanter was considerably above Nélaton's line, still without noticeable suppuration, and, at the end, with some mobility and a very useful limb.

He thought it so much a point of experience as to whether, in a given case, one should follow out conservative treatment or resort to more radical interference, that only the long-continued observation of a large material might entitle us to draw general conclusions. He must say that, as a principle, he was rather inclined to push the conservative treatment as far as possible; and his impression was, that even in cases presenting a more serious aspect, if only all the indications of hygiene and orthopedy are fulfilled and retentions of pus prevented as much as possible, good results can be obtained. Further, he thought that if by consequent general treatment one succeeds to alter in a favorable way the constitution of the patient and to check the progress of the local tubercular process, that then any kind of surgical interference will be followed by more satisfactory results, as far as complete recovery is concerned. Though feeling convinced that small particles of necrosed bone may be absorbed by the action of vigorous granulations, it is beyond doubt that a large percentage of cases will not recover *entirely*, unless tubercular sequestra are removed. Hence, eventually for these cases, the indication of excision falls into the scope of consideration. He had repeatedly tried to avoid total excision, and to perform more of a sequestrotomy, but he must say, that in all cases but one, he was obliged to add excision of the upper end of the femur, in order to get sufficient access to the diseased parts as would enable him to remove with some degree of certainty the structure involved. The one case above mentioned, in which several tubercular sequestra were removed from the anterior aspect of the acetabulum without touching the head of the femur, except to scrape away quite an amount of granulations, healed apparently, but it had not been under observation a sufficient length of time to enable him to determine whether recovery was permanent.

He regarded the necessity to remove so much bone, in excision of the hip-joint, as a great drawback of the operation, and did not think that the amount of shortening was as little as generally assumed. The question, what is the amount of shortening of the extremity in adults, who at an early age have been subject to excision of the hip-joint? is not settled yet, and is worthy of careful investigation. Suppose we have a young patient with tubercular ostitis of the acetabulum, and we remove, as might become necessary, a large portion of that bone, besides the separation of the shaft of the femur above the trochanter minor. In such a case we may have three or more inches of bone in its length

Digitized by Google

lost, and have, in addition to that, abolished what additional growth may have come from the preservation of the upper epiphysal cartilage. We ought to state how much that represents in the adult, in order to fix more accurately the question of indication for total exsection. The latter will, of course, always exist where the operation has to be done as a means of preserving life; and he thought that the standpoint of a good many surgeons and orthopedists, as a matter of principle not to do any exsection at all, was identical with sacrificing a certain number of lives which otherwise might have been saved. Especially the results of orthopedists are not absolutely conclusive, because the majority of the worst progressive cases do not apply to them, or eventually give up their treatment in order to search for some more speedy relief.

Regarding the very important question of functional result, he was not able to give a decisive answer. He had had some very good results after excision, and other cases in which, after excision, recovery was incomplete, or the functional result deficient. He had observed in several cases, where a great portion of the acetabulum had to be removed, in spite of consequent adduction during the after-treatment, that the shaft will not find a favorable point of support. One is able to make out, in such cases, a certain amount of slipping of the bones against each other, according to the more or less strong and tense fibrous connection; and he must further say that he was not yet convinced that under all circumstances a patient with movable joint, after excision, was better off than one with ankylosis in good position. The latter, with a slight amount of flexion, will always have a safe gait, and is not deprived of the advantage to be able to sit. Besides, his limb will probably not be as short as that of the former, who, to be sure, might occasionally offer an excellent result, at other times an incomplete one. He also thought one point worthy of attention, namely, whether the position of the limb, after excision as well as after conservative treatment, was a lasting one, and eventually how, later on, perhaps after a good many years, an unfavorable position might take place.

He had once, within the last seven years, seen general tuberculosis follow excision of the hip, apparently caused by the operation. The latter was done at an early stage of the disease. There were several sequestræ belonging to the head of the femur, and the patient died, in the third month after the operation, from tubercular meningitis.

DR. YALE said with regard to the amount of shortening which may occur, that (according to Ollier's experiments) if it was assumed that the growth from the upper epiphysis was absolutely abolished it was possible that, with the ordinary growth from that extremity of the femur, about nine centimetres might be lost. To that there may be added the atrophy from inactivity. He had measured many cured patients, some of whom had had abscesses, others none, with regard to the different sources and amounts of shortening, he had seen a tibia in a coxalgic person fall behind one inch or more, and it was fair to presume that the diminution in the growth of the femur is quite as much. If that be added to the other, it is possible that several inches may have been lost through simple inactivity.

The amount of functional use which a limb may have with anchylosis after an extensive disease of bone, was recently brought to his mind by a patient who fifteen years ago came under his care with abscess which had been totally neglected. There were many fistulæ, and in the spring of 1871 he contemplated excising the joint, and asked the opinion of Dr. Sayre, who said that excision would do but little good on account of the great amount of disease of the pelvic bone. He therefore treated the case as best he could without resorting to operative interference, and the patient recovered with anchylosis, is now a teacher in one of the public schools, although she still has six sinuses about the hip which discharge more or less, but the limb is in very good position, the actual shortening in the femur is one and a quarter inches, in the tibia about one inch, which is partially compensated for by tilting of the pelvis, and the remainder is nearly made up by hyperextension of the sound limb, and practically therefore she walks with a shortening of only about half an inch, and locomotion is with only a very slight limp.

He also recalled the case of a young man who, after he was cured, had thirteen cicatrices about the hip, and he was, when last seen, able to take an active part as member of a baseball club.

CORRESPONDENCE.

CHOREA.

To the Editor of THE MEDICAL NEWS.

SIR: The interesting editorial in one of your late issues on chorea raises a question, which seems to me is of so much interest and importance that I must crave a little space for its discussion. As I understand the editorial, the point is made that in chorea the tone of the ganglionic cells cannot be depressed, and that it is not possible for cells which are so diseased, as those I found in the spinal cord of the dog, to produce choreic movements as violent and as regular as those seen in the dog. The obvious reply to this is that whether it be possible or not the thing happened because the choreic movements were violent and the cells were diseased, and there was no other source from which the movements could have originated except the spinal cells. The amount of nervous energy necessary for choreic movements is much less than for voluntary motion. I believe always in the dog and usually, if not always, in the child, chorea is associated with a loss of power. The animal whose limbs are moving steadily and rapidly, may be scarcely able to drag them after him, and is more exhausted by a walk of a few rods than in health by as many miles. It must be remembered also that the change in the cells is a progressive one, and that there sometimes comes a condition of complete paralysis in which even the tremors may be lost. This represents the last stage of cell degradation, but long before this stage is reached the nutritive tone of the cell has undergone most marked diminution. I can see, myself, no reason for believing that at any time during the ordinary chorea of the dog is there an increase in the nutritive activity of the nervous protoplasm. My own experience being that always, so far as I could judge, there has been lessened power when any attempt at voluntary movement was made.

After all, however, this discussion is perhaps one

Digitized by Google

largely of terms, for we hardly have definite conceptions of what constitutes lowered or increased tone of a ganglionic nerve-cell. The important fact is, that there is an altered condition of the nerve-cell which leads it to discharge, at very short intervals minute amounts of nerve energy, but unfits it for storing such energy and discharging it, as it were, *en masse*, and also for sustaining a prolonged production of large quantities of force—*i. e.*, of enduring a prolonged voluntary effort.

Yours, H. C. WOOD.

PHILADELPHIA, Nov. 21, 1885.

NEWS ITEMS.

MONTREAL.

(*From Our Special Correspondent.*)

EXTRACTION OF LARGE CALCULI.—In the Montreal correspondence of THE MEDICAL NEWS, for February 7, 1885, Dr. Hingston is mentioned as having exhibited at a meeting of the Medico-Chirurgical Society, a calculus weighing nearly *six ounces* removed successfully from a young man by the lateral operation. He remarked, that he brought this large stone before the Society because he had lately seen it stated that Sir Henry Thompson had declared that it was impossible to remove a stone larger than *three ounces* by the lateral operation. At a recent meeting of the Medical Society, Dr. Hingston read a letter from Sir Henry Thompson in which the latter stated, that he had been only partially quoted, and that the context modified considerably the text, and the full text and context of his statement are as follows: "No incisions can be made in the region which belongs to that operation (the lateral) through which a calculus of three ounces or more can be extracted. *Laceration, either avowedly by instruments, or but half concealed under the name of gradual distention, invariably takes place, and that affecting very important structures, often to a large extent.*"

In making this correction Dr. Hingston observed, that while he admitted that the extraction of large calculi is often attended with more or less laceration, he thought the limit of three ounces below the possible, and should not decide the question as between the lateral and suprapubic operation, for in the last cases published in Canada, the suprapubic operation for a calculus of three ounces was fatal, whilst the lateral operation for a calculus nearly twice that size was successful and without injury to the neck of the bladder or other important structures.

CINCINNATI.

(*From our Special Correspondent.*)

DR. J. H. TATE, for many years Obstetrician to the Cincinnati Hospital, has recently resigned. In recognition of his past services, he was elected Consulting Obstetrician. Dr. G. M. Allen, Assistant to the Chair of Obstetrics at the Miami Medical College, will be Dr. Tate's successor.

DR. A. T. KEYT, one of our most highly esteemed physicians, died at his residence at East Walnut Hills, on the 19th inst. Dr. Keyt was known to the profession chiefly in connection with his labors to perfect the sphygmograph. A pattern of the instrument invented by him has met with marked favor in Europe, as well as in our own country.

DR. THOMAS ADDIS EMMET has been elected an honorary fellow of the Academy of Medicine in Ireland.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM NOVEMBER 17 TO NOVEMBER 23, 1885.

HEYER, ANTHONY, *Major and Surgeon.*—Member of the Army Medical Examining Board, now in session in New York City, is relieved from the additional duty of Attending Surgeon in that city, to take effect when Jos. R. Smith. Lieutenant-Colonel and Surgeon, shall have arrived in New York, and entered upon that duty.—*S. O. 267, A. G. O.*, November 19, 1885.

ELBREY, F. W., *Captain and Assistant Surgeon.*—Sick leave of absence extended six months, on surgeon's certificate of disability.—*S. O. 263, A. G. O.*, November 14, 1885.

REED, WALTER, *Captain and Assistant Surgeon.*—Granted leave of absence for one month, with permission to apply for one month's extension, to take effect about December 1, 1885.—*S. O. 115, Department of Platte*, November 18, 1885.

STRONG, NORTON, *Captain and Assistant Surgeon.*—Relieved from duty at Fort Union, New Mexico, and ordered for duty as Attending Surgeon Headquarters, District of New Mexico, and Post Surgeon, Fort Marcy, New Mexico.—*S. O. 171, Department of Missouri*, November 16, 1885.

CHAPIN, A. R., *First Lieutenant and Assistant Surgeon.*—Ordered for temporary duty at Fort Robinson, Nebraska.—*S. O. 113, Department of Platte*, November 18, 1885.

EWING, C. B., *First Lieutenant and Assistant Surgeon.*—Now at Fort Leavenworth, Kansas, ordered to proceed to Fort Reno, and report to Commanding Officer for temporary duty in the field.—*S. O. 170, Department of Missouri*, November 13, 1885.

SIMONS, JAMES, *Lieutenant-Colonel* (Retired), died November 11, 1885, at Baltimore, Md.

ORIGINAL LECTURES.

URETHRAL FEVER, AND DEATH FROM CATHETERISM.

A Clinical Lecture, delivered at the City Hospital before the Medical Class, November, 1885.

BY R. A. KINLOCH, M.D.,

PROFESSOR OF SURGERY IN THE MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA, CHARLESTON, S. C.

GENTLEMEN: I propose, this morning, to make some remarks upon the patient into whose urethra you saw me introduce a sound at our last meeting, and who afterwards died in consequence of this operation. The result was very unfortunate, but I regard it as one of the "calamities of surgery" that could scarcely have been foreseen or prevented. The poor sufferer died thirteen hours after the passage into his bladder of a medium sized (No. 24 F.) steel sound. I will first show you the specimens prepared for me after the autopsy, and will read you from an excellent authority on this subject the report of a few similar cases to show you that death under similar circumstances has been before encountered by excellent surgeons, and then I shall comment on the case in question. (Bladder and kidneys exhibited, and extracts read.)

This man had been in the hospital for some time under treatment for malarial fever. He was also known to have a stricture of the urethra. There had been unsuccessful attempts by physicians outside of the hospital to introduce a catheter into the bladder. Such failures are very common where there is sudden congestion of the parts forming the deeper portion of the urethra. An instrument may be readily passed one day, and in the same hands it may not pass another day. I deferred my examination of the urethra until the man had recovered from his malarial fever, for the retention of urine had been only occasional, and not urgent. Prior to my operation, which was intended to be only a preliminary stretching of the contractured canal, the pateint was given ten grains of quinine and a quarter of a grain of morphine. His urine had been carefully examined, and was found free from albumen. This is a very important matter, for the danger from all operations, and especially those upon the urethra, is greatly enhanced if there be any disease of the kidneys. Such disease, as a rule, should preclude any serious operation.

You saw what transpired at my clinic, and how I carefully examined the urethra, first with the bulbous bougie, and then with the steel sound. I then resorted to several filiform whalebone bougies, but did not try a sound smaller than the one that finally entered the bladder. The small elastic bougie established the existence of a false passage at the bulbous portion of the canal and the hemorrhagic disposition indicated a granular condition of the mucous membrane, and a soft stricture. I then felt assured that, with proper manipulation, the steel sound was the instrument most likely to pass. This I could guide, and thus would not enter any false passages that existed. Aided by my finger in the rectum, the beak of the sound was a little elevated, and then with very moderate force it was urged on, and easily entered the bladder. The instrument was now freely movable in the bladder, nor did the urethra tightly grasp its shaft. I was convinced that the stricture was only a congestive one, and that there was no old organic thickening that would require cutting or long and careful attention. I congratulated myself upon my good fortune, and the future prospects for the sufferer. The autopsy, as I will explain, confirmed my view of the character of the disease.

But how uncertain at times is surgery. Three hours after my patient had been put to bed, he was attacked with a severe chill accompanied with vomiting and great restlessness and anxiety. The house surgeon reports that very soon the temperature ran up to 106°. Subsequently there were a rapid and weak pulse, great depression, heart failure, delirium, and the poor fellow died at one o'clock A. M., thirteen hours after the operation. Examine this specimen and you can see no pathological condition to account for the fearful result. And yet the simple passage of the sound, and the slight divulsion which it effected, caused all the evil. Some of the cases I have referred to, show that death has followed even gentler operations of this same kind. Once before I encountered a similar result from an internal urethrotomy performed with Otis's dilating urethrotome, in the case of a young and vigorous man.

When a false passage is made you might expect traumatic fever to supervene, or urinary infiltration to result, and finally death may be traced to such lesion or condition. But there is no very sudden death from such accidents. Suppuration and irritative fever, or septic trouble, will precede death and indicate the initial lesion. In cases like the one we are considering, the rapidity with which the result was reached points clearly to a nervous implication. The death is almost like that due to shock after operations; but the high temperature points to something more. Can septic trouble supervene and kill so rapidly? This is difficult to conceive of. If nerve pathology was not yet so obscure, we might better interpret the phenomena met with and explain the result. As it is, I can only remind you of some facts which go to show how intimate is the sympathy between the urethra and the sympathetic system of nerves. A man in robust health often faints when a bougie is passed for the first time. Let me advise you, unless you know your subject, always to place him in the recumbent position when you introduce a bougie or a catheter, for the reason just given. The fainting under the passage of the instrument clearly indicates a reflex nerve influence. You can imagine that, if this should be carried to an extreme degree, death might result. Again, we not uncommonly see what is called urethral

Digitized by Google

fever follow the passage of a catheter or an operation on the urethra. There is a chill, followed by fever, and this latter by a profuse sweat. Sometimes these symptoms are repeated again and again, like in a malarial intermittent. One condition is often mistaken for the other. I have never seen a fatal result in this variety of urethral fever, where the paroxysmal character was so defined, but I have at times felt alarmed for the safety of the patient.

When urethral fever follows catheterism, or when a decided chill is the consequence, I would caution you as to the repetition of the operation. You should be careful and use all the means we possess for controlling the irritability of the nervous system. Give morphine with atropine, or chloroform, or aconite, in advance of the operation. Use cocaine to modify the sensibility of the canal, and all the time examine carefully as to the condition of the kidneys. I cannot say that I have seen any marked advantage from quinine used in this connection although I habitually prescribe it. Now if our unfortunate case is to be classed as one of urethral fever, then we must call it the *fulminating* form, in contradistinction to those milder cases that I have referred to. The suddenness and rapidity of this case were indeed terrible. We can scarcely be more impressed or startled with the prompt collapse or death that comes of violent forms of cholera. It matters but little whether we conceive a poison operating through the blood, or whether we infer a more direct influence spent upon the great nervous centres.

I must tell you, before concluding, that the autopsy revealed the fact that both the liver and spleen had suffered from the influence of malarial disease. But I cannot assume that this accounts for the fearful end. We know of like results where no such complication existed.

The shock, heart failure, and death following operation most impress us, and illustrate cause and effect. I have regretted that I did not administer an anæsthetic before operating. This may, in such cases, afford some protection to the nervous system.

To go back to the autopsy and its revelations, as seen in the specimens before you. The bladder, you observe, looks healthy, and the urethra exhibits here behind the bulb some evidence of the divulsion; the mucous membrane is congested, thickened, and looks as if split or fissured. Here you see an old false passage at the beginning of the bulbous portion of the canal, and there is a little bloody extravasation in the submucous tissue, which extends up between the rectum and bladder. This last is nothing remarkable, and was to be expected as the result of our operative procedure. It could have had nothing to do with the death. There is another matter more worthy of note. After section of one of the ureters, we find a little muco-pus exuding upon pressure. Such secretion could not have been in any amount, or we should have detected albumen in the urine during life. There is some congestion of one kidney, while the other looks entirely healthy. Some bloody urine was found in the bladder, but it cannot be positively stated whether this was secreted before or after the operation. Blood may have passed back into the bladder from the urethra and mixed with the urine, or it may have come from the congested kidney. No urine was passed by patient after the operation, but certainly there was no uræmic poisoning.

Before leaving, let me give you one or two practical hints as to catheterism. In this operation there is often exhibited very bad surgery. But few men are adroit with the use of the instrument, and in the hands of many it as often perforates the urethra as it goes smoothly on into the bladder. If the beak is elevated too soon, it wounds the anterior part of the canal in front of the triangular ligament; or if it is urged along the floor of the canal and too much toward the rectum, the posterior wall is perforated at the bulb. You should let the instrument go easily on by its own weight, as it were, the beak close to the upper wall, and only when its progress is stopped should you gently depress the handle and cause the beak to follow the natural upward curve of the deep portion of the canal. I have had some curious experience in urethral surgery. Only yesterday I passed into the bladder, without difficulty, a No. 20 F. catheter in the case of a man brought here from Augusta, and whose bladder had been aspirated above the pubes to relieve retention. I once saw a perineal section that had been made by a reputedly good surgeon of this city, for an impassable stricture. Following the section, a large catheter had been passed into the urethra and up between the bladder and the rectum. There the instrument had remained for many days, with the belief that it was in the bladder. The urine had continued to pass alongside of the catheter, but not through it. There was abundant suppuration, and yet the man survived after I had removed the instrument, and afterwards inserted it into the bladder through the natural way. You may ask me whether there is no great danger from these false passages. There is always some danger, but fortunately the perforations are made from before backwards and upwards. This, to a certain extent, guards against urinary infiltration, and admits of drainage in the event of ensuing suppuration. But where a false passage results from ulceration behind a tight stricture, the urine necessarily enters little by little, and we have the starting-point of fistulous tracks which slowly extend, perforate the tissues in numerous directions, and open on the perineum or on the cutaneous surface of the scrotum. We shall see and speak more of these hereafter. When using the catheter, you find that it has wandered from the right direction, and has not entered the bladder, and you find much bleeding from the urethra, you can infer that you have perforated the walls of the canal. Now you should withdraw the instrument, keep the patient at rest for some days, watch his symptoms, and do not, unless there be urgent retention, attempt to pass another instrument for many days.

VENEREAL BUBO.

AN INQUIRY INTO ITS RELATIVE FREQUENCY, AND BEST METHOD OF TREATMENT.

BY S. T. ARMSTRONG, PH.D., M.D.,
PASSED ASSISTANT SURGEON U. S. MARINE-HOSPITAL SERVICE.

WHILE the word "bubo" has been employed to describe an adenitis in any locality, it should, etymologically, be used only in reference to an inflam-

mation of the lymphatic glands of the groin. The conditions causing bubo may be, traumatism; bubo coexistent with general adenitis in plague; tubercle; cancer of the lower extremities, penis, or pelvic viscera; erysipelas, pyæmia, or septicæmia, consequent upon an injury of the lower extremities; excessive venery; balanitis; gonorrhœa; soft chancre; or carried into a gland, the usual processes of inflammation ensuing in consequence thereof. Sometimes this is limited to the gland, occasionally the adjacent tissues are involved. Microscopical sections of such a gland show hyperplastic formation of the cellular substance and reticulum. Rokitansky considers that the former process is more extensive than the latter.

chancre. In this paper, reference has been made only to bubo consequent to the latter three diseases, they bearing the most frequent causal relation.

The pathology of bubo is an absorption by the lymphatic vessels of an irritating substance which is The inflammation may subside, and the enlarged gland gradually becomes smaller by the absorption of the neoplastic tissue, or there is but little absorption, and chronic induration remains, or necrosis of the gland substance results in pus formation. Baum-

Digitized by Google

ber states (Ziemssen's *Encyclop.*, vol. iii. p. 120) that the involution effected through fatty metamorphosis may, under certain circumstances, eventuate in caseous and calcareous degeneration.[1]

The time of the appearance of bubo after the commencement of a venereal disease, seems to depend as much upon the idiosyncrasy of the individual, as upon the date of absorption by the lymphatics. Dirt, negligence, and length of prepuce, are predisposing factors.

Bubo as a complication of gonorrhœa is rather rare; by referring to the appended statistical tables, it will be seen that $2\frac{7}{10}$ per cent. of the combined total of cases of gonorrhœa and gonorrhœal bubo, treated by the U. S. Marine-Hospital Service during the past four years, had bubo. In this connection I would state that the cases in this table are, if not entirely in males, so nearly so, that the question of sex would be of no import toward vitiating the result.

During a residence as Assistant Physician at the St. Louis Female Hospital, I failed to meet with a case of gonorrhœal bubo in woman, and consider—from accessible reports—that this complication is rare. Several times I found abscess of the vulvo-vaginal gland, and its situation would suggest its easy inflammation.

In the question of race, notwithstanding the alleged tendency of the negro to suppuration, the long prepuce retaining the purulent secretion, and his carelessness about an attack of what he calls "runnin' range," I have only—in a recent series of cases—recorded one case of gonorrhœal bubo in forty-four cases of bubo; while in twenty cases of bubo in whites, three were gonorrhœal. The statistics of New Orleans Charity Hospital for the past five years, record seven cases of gonorrhœal bubo in whites, and four in negroes.

This form of bubo is of long duration, the following cases being typical of each stage of the inflammation.

CASE I.—M. R., æt. 34 years, laborer, white, had gonorrhœa early in August, 1879, and later a bubo in the right groin. As the latter, after an acute inflammatory stage, reduced in size, he neglected treatment until the first part of October, when he was admitted to the St. Louis City Hospital for it and gleet. The latter was relieved, but the bubo remained when he left the hospital the last of the month.

CASE II.—J. F., æt. 21, white male, engineer, had gonorrhœa in January and also in June of 1883. July 6, the inguinal glands in each groin enlarged; despite this, he continued both his occupation and fornication. August 9 he was admitted to the hospital (U. S. M.-H.), and both groins lanced. He insisted upon returning to work August 13. September 12 he reported again, stating that he had opened four abscesses in right groin, and three in the left, since leaving the hospital. There were several fistulous tracts in each groin.

The method of treatment for this form of the disease is not different from that applicable to other buboes.

In passing to the consideration of suppurating bubo complicating soft chancre, a reference to the accompanying tables will show that the usually accepted statistics of this subject give too high a percentage. In the U. S. Marine-Hospital Service, all seamen presenting applications for relief receive treatment either in the hospital or dispensary. My experience in the municipal institutions of St. Louis permits the statement that only the severer cases, or absolute paupers, were admitted to treatment for venereal disease. The same rule, I think, existed in Charity Hospital, New Orleans. Consequently, the percentage in the first instance is only 16 per cent.; in the second (combining Dispensary and Hospital Relief, thus resembling the Marine-Hospital statistics), 34 per cent.; and in the last institution, $26\frac{5}{10}$ per cent.

Relative to sex, the statistics of the St. Louis Female Hospital show 18 per cent. of buboes. As regards race, in Charity Hospital, New Orleans, the percentage of buboes in whites is 33 per cent.; in negroes, 20 per cent. In a recent series of cases of my own, the percentage of bubo in whites was $22\frac{8}{10}$; in negroes, $24\frac{5}{10}$.

The bubo accompanying soft chancre may become phagedenic, and by its destruction of important parts prove fatal. A. Vater and G. P. Juchs[1] report a case of perforation of the intestine, and death. Dietzmann,[3] Labbé,[3] and F. D. Lente,[4] each report a case of peritonitis following bubo. Aron,[5] and New Orleans Charity Hospital,[6] each give a case of perforation of the femoral vein, and fatal hemorrhage. Callender,[7] C. T. Poore,[8] and R. V. de Lisle,[9] each report a case of bubo perforating the femoral artery. P. Cullen[10] reports a case of fatal tetanus from bubo. Aside from such complications there may be destruction of a large extent of skin and superficial tissue. I presume most persons are familiar with Ricord's case, referred to by Bumstead and Taylor, where the phagedena involved the loin, buttock, entire circumference of thigh to below the knee, despite all preventive measures, and fourteen years later the ulcer had not completely healed. This indolency frequently follows phagedena.

CASE III.—E. L., æt 26 years, white female, was transferred to my charge, in the St. Louis Female Hospital, in 1880. She had been in the institution for some months for an indolent ulcer of the left groin, and abdominal parietes, extending from pubes to crest of ilium, and to within a short distance of the umbilicus. This was the result of a phagedenic bubo incurred early in 1879. The efforts of my

[1] In the *American Journal of the Medical Sciences* for October, 1885, Dr. A. Victoria Scott, of Philadelphia, reports a case of calculi removed from cysts of the vulvo-vaginal glands in a mulatto, aged 49 years. When 43 years old the patient had abscess of these glands, with itching and burning in vulva, and an irritating leucorrhœal discharge. While this adenitis was not inguinal, the relative frequency of inflammation of this gland in gonorrhœa in women, is referred to elsewhere. While not stating that in this case the vaginitis was specific—so-called—the identity of the latter and ordinary vaginitis is suggested for consideration.

predecessors and myself failed to improve the condition.

CASE IV.—C. J., æt. 26 years, male negro, roustabout, admitted to U. S. Marine Hospital, Memphis, September 29, 1884, for indolent ulcer of each groin. In the summer of 1882, he had a venereal sore, and double bubo. The latter were lanced by a physician in St. Louis. He was drinking a great deal of whiskey at that time, and thinks this caused the phagedenic condition and prevented healing. While caustic applications destroyed the unhealthy granulations, cicatrization did not follow, nor would skin grafts adhere. Patient died of pneumonia January 14, 1885.

The indurated bubo is usually accepted as the complication of hard chancre. The following case is typical:

CASE V.—M. L., æt. 20 years, white male, seaman, had several small pimples on corona some eight days after coition. August 31, 1882, two weeks after appearance of pimples, he applied to me for relief, having a mucous patch on penis, no induration about it; indurated bubo in each groin. September 6, a macular syphilitic eruption appeared. Constitutional treatment cured the buboes.

Where the hard chancre is phagedenic, the induration of the glands is not necessarily followed by suppuration:

CASE VI.—J. L., æt. 32 years, male negro, had a single sore on glans penis in 1870, which destroyed one-half the glans. The inguinal glands were indurated, but did not suppurate. He was treated in the U. S. Marine Hospital, St. Louis, for this and an annular syphilide. July 27, 1881, he came under my treatment for tertiary symptoms, and this history was verified by an examination of the body.

Whether seamen are more liable to mixed sores, and also indurated buboes eventually suppurating, I am hardly prepared to say. But Cases VII. and VIII. are far from rare forms in that class of patients:

CASE VII.—O. W., æt. 25 years, white male, mate, treated August 23, 1883, for an irregular sore on glans penis, and indurated bubo of left groin. The latter rapidly suppurated, and on September 3, it was lanced. While no secondary eruptions appeared, and the patient took no mercury, yet he had osteocopus and sore throat during the winter, and other evidences of constitutional infection. He was given mercury, which he took irregularly. In April, 1884, he had a very severe attack of specific iritis.

CASE VIII.—A. Y., æt. 32 years, male negro, cabin-boy, applied for relief for an irregularly shaped sore and indurated bubo on June 19, 1885. On August 22, he was admitted to the hospital, and the bubo lanced. About the middle of September an annular eruption on body, with sore throat and alopecia, was treated.

This peculiar *sequela* of indurated buboes was first reported by P. A. Surgeon H. R. Carter, U. S. M.-H. S.,[1] who gives statistics of 231 cases of syphilis each in whites and negroes. There were five cases of suppuration of the inguinal glands in the whites, and thirty-nine in the negroes. Dr. Carter says: "This is so common, that the suppurating bubo is almost without significance in the diagnosis between the 'infecting and non-infecting' sore." My experience confirms this.

The first consideration in treatment is the possibility of aborting the acute inflammation. To this end, rest is a most important adjunct. Heat, in the form of poultices, is soothing, but tends to promote suppuration. The use of caustics as counter-irritants is too severe a procedure. Compresses are painful, tedious, and inferior to other measures. The frequent application of tincture of iodine, or of this with belladonna, destroys the epidermis, which usually remains as dead cuticle over the new formation; consequently, subsequent applications have but little opportunity to exercise any topical influence.

Dr. Otis, and also Dr. L. D. Bulkley, of New York, have advocated sulphide of calcium. In doses of 1/8 to 1/4 of a grain every two hours, I have aborted gonorrhœal or chancroidal buboes, and find the drug very useful.

In specific buboes, inunction of the oleate of mercury and constitutional treatment have been, with me, most satisfactory.

In all forms of bubo, excellent results may be obtained, in the early stage, by the intraglandular injection of carbolic acid (10 to 40 per cent. solution), or tincture of iodine (pure), or bichloride of mercury (5 to 20 per cent. solution). The latter may be combined with iodide of potash (making then a biniodide solution), and is useful in syphilitic bubo. In all cases, I first wash the skin with a carbolized solution, and if very tender, cause local anæsthesia with an ether spray. The hypodermatic needles are carefully cleaned, and the injection made into the median portion of the gland. These injections may be repeated daily, though I have obtained as satisfactory results by using injections every other day. Great care must be exercised to prevent the escape of the injecting fluid into the subcutaneous tissue. In some cases the injections cause such great pain that their use must be abandoned.

A method of interstitial medication has been suggested by Dr. M. A. Brondel,[1] of Algiers, of applying compresses wet with a solution of iodide of potash, or bichloride of mercury, over the enlarged gland, and placing on this the negative electrode of a galvanic battery, the positive electrode being placed over the other groin. The solution is decomposed by electrolysis, and the iodine traverses the tissues to the positive, or the mercury to the negative, electrode. This discovery is too recent for any observations on my part, and Dr. Brondel has not reported its use for this purpose.

Where suppuration has occurred, all these measures are futile. A case was reported in the service of Dr. McBurney[2] of an indurated chancroidal bubo not improved by intraglandular injections, in which the bubo was extirpated. I have tried this plan in indolent bubo in a white man and

Digitized by Google

a negro, with a view to diminishing the duration of treatment. If we were assured of phagedena in every case, this might be an excellent procedure, before the gland ruptures. But for ordinary buboes, in consideration of the close proximity of important vessels, of the possibility of pus entering the peritoneum through the inguinal canal, and of the possibility of burrowing in the abdominal fascia, I think the operation is one rarely to be employed.

For the evacuation of pus, Le Pileur proposed aspiration, and washing the cavity out with various solutions. My employment of this method in the City and Female Hospitals of St. Louis, showed that it was painful, protracted in application, and not always successful in accomplishing the desired end.

The use of horsehair or a seton for drainage through a small puncture, advocated by Bodnar, Déchanet, and Bascoul, has never met with favor.

Multiple puncture of the skin over the bubo does not offer the advantages of a free incision.

The most satisfactory method is to wash the surrounding skin with a carbolic acid or bichloride of mercury solution, shave the hair from the adjacent region, produce local anæsthesia by cocaine or the ether spray, and make a free incision in the gland; afterward dress with the same solutions, and favor suppuration and granulation by poultices.

The average duration of confinement in bed in cases treated as above, is twenty days, and I have obtained no better results with other methods.

Where exposed glands remain in the incision, they should be removed with scissors. I have never had the misfortune of phagedena resulting in a case under my treatment from the beginning; this immunity is attributable to thorough cleanliness, and antiseptic precautions.

Where the process of granulation is slow, curetting, the use of chromic acid solution, or arsenical paste, are the most advantageous measures.

MEMPHIS, TENN., November, 1885.

A CASE OF COMPOUND EPIPHYSIAL DIASTASIS.

BY R. W. KNOX, M.D.,
OF HOUSTON, TEXAS.

THE following case is recorded on account of its rarity, and to show that such an injury may be followed by a complete restoration of the parts:

Dean C., aged 16, while racing, received an injury from his horse falling upon him, causing considerable shock, and producing the following lesions, as discovered when brought in for examination.

Severe pain was complained of in the arm and shoulder, and upon removal of the coat the shaft of the humerus was found protruding through the skin for the distance of one inch over the outer and rather inferior aspect of the deltoid muscle. The extremity of the bone presented a transverse surface without spicula; comparatively smooth to the touch, as if released from cartilaginous union, and suggesting the diagnosis of epiphysial separation. The head of the humerus could not be reached with the finger, although the wound was sufficiently large to admit it (the shaft still protruding), but by external manipulation was found to be *in situ*.

Reduction was easy under chloroform. To overcome muscular action and keep the parts at rest, this apparatus was used: A splint of sheet zinc was prepared, extending from the axilla to the finger-tips. This was notched at the bend of the elbow, made rectangular, and accurately fitted with padding to the inner side of the arm. A felt cap, notched to allow drainage from the wound, was applied to the shoulder, and both arm and forearm secured to the chest with a roller bandage.

The patient was of delicate build, with a malarial cachexia, and had recovered only a few months previous to the accident from a severe attack of pneumonia. No fever appeared until the fifth day, when the temperature arose to 105° F. in the evening, and continued with evening exacerbations until the tenth day, when the fever passed off, and the patient went slowly on to recovery. At the end of three months all splints were removed, and when last seen, six months from the date of his injury, the patient had every motion in his arm, and could use it as well as ever. Success is attributed to the complete rest enforced in the early stages of the treatment, together with the close-fitting and immovable character of the dressings; antisepsis and drainage were used for the wound.

The result in this case opposes the idea held by many, that diastasis at this point is usually followed by vicious union or atrophy of the parts, on account of the injury done to the fibro-cartilage that separates the epiphysis from the shaft. One author says that "injured epiphyses are prone to inflammation, going on frequently to suppuration, periostitis, and even osteomyelitis."[1] Is it not possible that they have mistaken a joint injury for an epiphysitis? It would seem that cartilage, which has so little blood, would not be liable to be the starting point of much inflammation. Certainly if an injury to an epiphysis is fraught with such bad results when of a simple nature, how much more surely would this hold true when the injury is such as is described in the case above. However, in this case, with a compound separation there is now no appreciable difference in the size of the two arms, and only a scar remains to tell the tale that there was ever an injury.

A NOTE ON ATROPIA IN ACUTE CORYZA.

BY R. GRAY, M.D.,
OF JACKSONVILLE, FLORIDA.

IN all recent works on nasal diseases no mention is made of atropia as a remedy in acute coryza. The use of the drug in this disease is by no means a new one, and I make no claim to advancing a new idea. My object is simply to urge upon the profession a large use of the remedy, and note the results.

The first case in which I used atropia in acute coryza, was that of a man in middle life, who had "caught" a severe "cold in his head" several days previously. When he came for advice the disease had reached an extreme stage. There were severe frontal headache, a hot, burning sensation in the

[1] See Surgery of the Epiphyses, by Mr. Wheelhouse, Brit. Med. Journ., March 7, 1885.

Digitized by Google

nose, forehead, and cheeks, there was some conjunctivitis, and very profuse mucopurulent discharge, which was extremely irritating. The skin about the nose was irritated and inflamed, and the general condition was one of great misery. Atropia was given with the idea of decreasing the amount of the discharge. The dose was $\frac{1}{120}$th of a grain, repeated after four hours. It had a most marked effect, and the next day the patient was quite free from headache, heat, and swelling, and from discharge.

Since then the remedy has been tried in a large number of cases, in all stages of the disease, and at all ages, with uniform success. It is now my established practice, and is preferable to cocaine in this, that no local application is needed to the nose, thus saving a very painful manipulation.

The only objection that has been made to the treatment, is where the eyesight is troubled. But the dose needed to cure the coryza is not sufficient to produce much disturbance of vision. It is only necessary to influence the secretion, and an extreme degree of dryness of the throat and nasal passages is of no advantage.

A CASE OF INTUSSUSCEPTION.

BY JOHN FERGUSON, M.A., M.D., L.R.C.P. ED.,
ASSISTANT DEMONSTRATOR OF ANATOMY, TORONTO SCHOOL OF MEDICINE, TORONTO, CANADA.

THE following case presents some interesting points, both in its history and treatment.

The patient was a strong, well-built and well-nourished Scotchman of thirty-seven years. When called to see him about 9 P. M., I was informed that he had been suffering considerably from pain in the abdomen. It was for this he sought my service. On making inquiry, I found that he had been troubled with constipation for some two weeks, which he thought was caused by eating dry dinners. Three days before my visit he had taken two doses of castor oil, amounting in all to two ounces. The bowels were freely moved by these doses. On the second day all action of the bowels ceased, and a general but undefined pain came on, reaching a point of considerable severity on the evening when my first visit took place.

As I did not expect any very serious results, I gave him a hypodermatic injection of one-third of a grain of morphia; and left two morphia pills, each containing one-quarter of a grain, to be used during the night if required. On returning in the morning, it was found that the pain had caused more disturbance than was to be expected, considering the amount of morphia administered.

At this visit I learned that on two previous occasions, separated by about a year each time, he had had some pain in the abdomen, lasting, in the latter of these attacks, some three weeks, following an attack of diarrhœa, and gradually disappearing. Careful examination of the abdomen revealed a small tumor a little below, and to the right of the umbilicus. This was distinctly tender to the touch. The tumor was elongated, placed obliquely in the abdominal cavity, and not very firm. The pulse was 81 per minute, and rather hard; the temperature was 101.3°. There had been no action of the bowels during the night.

On the occasion of this visit, I administered a warm water and soap enema, sufficient in amount to fill completely the entire colon, having passed an elastic nozzle some eight inches into the bowel. When this fluid was rejected by the bowel, there was scarcely a trace of fecal matter in it. Another hypodermatic of morphia, one-third of a grain, was given, and doses of one grain of opium ordered to be taken as often as the pain justified their use. Warm applications were directed to be applied to the region of the tumor.

In the evening the temperature remained the same. The pulse was 95; the pain modified, and there was some nausea, though there had been no vomiting. There had been no action of the bowels subsequent to the enema. The opium treatment was continued along with the warm applications.

On the day following, the patient appeared more anxious; the pulse was above 90; the temperature was 102°; the nausea continued, but without vomiting. The bowels had not moved. The tenderness over the tumor was increased, though the latter was not so easily recognized. The patient remained in this condition throughout the day.

The following morning there was moderate meteorism; the tenderness and tumor still about the same. No vomiting had taken place, though the nausea was increased. There was also a slight muco-sanguineous discharge. This discharge continued more or less during the remainder of illness up to date on which the intussuscepted portion of the bowel was passed.

From this date on, for four days, the meteorism increased; never becoming very great, however. On only one day of the illness, the sixth from the commencement of my attendance was there vomiting. It was of a bilious character, but not in the least stercoraceous. This is noteworthy, as it afterwards proved to be a case of entire intussusception.

The opium treatment was continued in full doses throughout the case. The nourishment consisted in rich meat extracts, eggs, and milk peptonized.

On the seventeenth day of my attendance the patient evacuated four and a half inches of the small intestine. From a careful examination of this it was concluded that it must have come from about the lower end of the jejunum, or the upper end of the ileum.

The same nourishment and the opium, though in smaller doses, were continued. On the seventh day after the discharge of the portion of the intestine there was a small fecal motion. The recovery was steady and unbroken. The patient slowly resumed solid food, the opium was gradually lessened, and finally omitted. The patient was sufficiently recovered to return to his work in the seventh week from the date when I was sent for.

I would call attention to the absence of any very severe symptom, while the discharge of the portion of bowel settled beyond doubt the real nature of the case. As to treatment, all that need be mentioned is the use of a rich but easily absorbed nutriment,

Digitized by Google

one which left but little residue to be disposed of, and the steady and free use of opium up to the date of the separation of the intussuscepted portion of the intestine, and for some time after.

HOSPITAL NOTES.

DISPENSARY FOR NERVOUS DISEASES, BALTIMORE.

Service of JOHN VAN BIBBER, M.D.

CLINICAL NOTES.

Torticollis.

A. B., nine years of age, presented herself for treatment, July 20, 1885, suffering with wry-neck. She gave the following history: About one month ago, she was suffering with toothache on right side, and on same day she received a blow on same side of neck. She was not able to sleep that night on account of pain, and next morning she found her head drawn to left side, and any attempt to straighten it caused considerable pain. She was treated with various applications, but as the head continued to be drawn more to the side and the neck to become more painful, she applied at a dispensary in her neighborhood for treatment. She was put under a course of medicine, and the right side of the neck was blistered several times, but at the end of a month her condition was in no way improved.

She then applied to this dispensary. The head was carried very much to the left side, with the chin almost on a line with the left shoulder, and the left sterno-cleido-mastoid much contracted. The right side of the neck was considerably swollen and sore from the blisters, from the spine as far forward as the sterno-cleido-mastoid muscle. Gentle traction caused considerable pain. She was slightly anæmic, otherwise her condition was good. Examination with faradic current showed the left sterno-cleido of normal contractility and very rigid, while that on the right side was stretched, somewhat atrophied, and did not respond readily to a strong current. As the application of a current was extremely painful on account of a sore on the neck, soothing applications were used for a few days, and she was put upon tonic and ferruginous treatment.

At the end of a week the use of the faradic current was begun daily. At the same time, and after applications of the current, she was made to suspend herself for several minutes every day in the Sayre's swing. Under this treatment she improved rapidly. The right muscle grew stronger after each application of electricity, and gradually the head could be brought into its normal position.

She came for daily treatment until August 19, 1885, when she considered herself cured, and did not return for some weeks, although there still was slight weakness of movement. She came again to Dispensary on September 11, 1885, at which time she was carefully examined, and it was found that both sterno-cleido-mastoid muscles acted normally, and that all movements of head and neck could be normally performed.

Remarks.—The deformity in this case differed from that of an ordinary wry-neck. The head was drawn to the left side, and the chin turned to the same side instead of toward the right shoulder. The first inflammation in the muscles of the right side of the neck caused her to assume this position, which, having continued for a long time, induced atrophy and a partial paralysis of the overstretched sterno-cleido-mastoid muscle of the right side. This, however, still retained sufficient power to keep the head in position to cause the least disturbance from jar or movement.

This patient has now entirely recovered, and her treatment has been an instructive example of what can be done to prevent deformity. Without proper instruments this good result could not have been accomplished, and the continuation of the deformity over a long period would have induced a permanent contraction of the muscles, which could have been remedied only by a tenotomy.

Basilar Effusion.

R. B., two years and four months of age, was presented for treatment August 21, 1885. His mother gave the following history: Up to May 25, 1885, the boy was well and hearty; he could walk and take care of himself as well as any other child of his age; he was altogether an exceedingly bright child, could talk intelligently and make himself generally understood. Would always call his mother's attention whenever he wanted to micturate, etc.

The boy enjoyed good health up to May 26, 1885. A few days before this date his mother remarked that he passed worms in the stool—the ordinary ascarides vermicularis. She gave him wormseed without consulting a physician, and not knowing exactly the dose she gave him. On the morning of the first day he was taken sick shortly after going into the yard to play, and was there for an hour. On looking for him, his mother found him eating the leaves of a flower plant, commonly called blue flag (iris versicolor). How much he had eaten could not be ascertained. He ate his usual dinner, and shortly after was put to bed to take his afternoon nap; he remained asleep until about four o'clock, when he called for water, which was given him, but was at once vomited. His face was flushed and swollen, and his skin very hot. On examining the vomited matter, some pieces of the flower leaves swallowed in the forenoon were found.

Shortly after he was seized with convulsions, which were violent and protracted. A physician was sent for, and after the action of a purgative the stool was found to contain considerable quantities of blue flag leaves. The convulsions were violent, and could only be controlled by chloroform inhalations. These seizures continued for more than a week, when they were finally controlled. The child was then exceedingly weak, had lost the power of speech, was unable to walk, and did not pay attention to anything. This was his condition when presented at the dispensary August 21, 1885. The patient's general expression was idiotic; he walked with an oscillating gait and would often fall, and, while he was not paralyzed, a very decided weakness was manifested. He was much emaciated, probably due to the fact that he vomited nearly everything given him to eat.

On examination it was found that the boy was very

Digitized by Google

deaf, and was unable to grasp anything tightly. He attempted to chew and swallow everything that came within reach. Feces passed involuntarily; slept little at night. Was very restless during the day; constantly walking and constantly crying.

Basilar effusion was diagnosed, with unfavorable prospect for recovery. Patient was put on strong alterative treatment: various mercurial preparations by inunction, his stomach symptoms were controlled with small doses of calomel, alternated with pepsin, and stimulating applications to epigastrium. His insomnia and restlessness were diminished by conium, etc.

His general condition improved, he slept well, has ceased to cry in the idiotic manner, and is quieter; from being emaciated and weak, he has grown strong, and appears well nourished; his stomach is in a much better condition, though he still vomits occasionally. Both upper and lower extremities are stronger, though the oscillating gait is still perceptible; and above all, his mother declares that he appears to show many signs of intelligence in noticing objects around him, and in calling his father's name, which he has not done since his first illness.

Remarks.—The serious brain lesion in this case was no doubt due to the force and duration of the convulsions, which were of toxic origin. This result is a strong argument in favor of the active treatment of convulsions in children, from whatever cause produced. The post-febrile brain lesions in children have ruined irrevocably many who otherwise might have developed into strong and healthy adults. The mercurial inunctions, potass. iodide, hydrarg. tinc. iodide, the stimulating lotions to spine and abdomen, and local treatment of the gastric disturbance, have brought about a better result than was anticipated. I am led to think that the vomiting was of central origin, for with the improvement of the cerebral symptoms this difficulty has been overcome.

The curious fact of the child's showing such a morbid and irresistible desire to bite and put everything in its mouth, shows that the vomiting produced by the poison left a decided impression of the pneumogastric centres, and this result was increased and prolonged by the subsequent effusion and meningitis.

From the progress already shown by this patient, I think we can safely look forward to a more rapid and decided improvement.

MEDICAL PROGRESS.

REFLEX MOVEMENTS IN THE BLOODVESSELS OF MAN.—G. FANO (*La Salute*, 1885) has determined by experiment:

1. That the bloodvessels react to electrical stimulus.

2. The time of reaction is always long, varying between two and seven seconds, according to the condition in which the patient is found, and according to the locality to which the stimulus is applied.

3. The vascular constriction consequent upon electrical stimulation is more apparent in sleep than when the patient is awake, and occurs first in the upper extremities, afterward in the lower.

4. The constriction of the vessels of the lower extremity is, perhaps, more slowly manifested than is that of the upper extremities, but persists through a longer period, the vessels of the upper extremities regaining their normal volume very rapidly.

5. During fasting, the vessels respond but slightly to stimulants, but react with great energy after a full meal.

6. Other stimulants than electricity produce the same effect, and the constringing of the vessels is always proportionate to the intensity of the stimulation, and the greater the psychical activity the more intense and more rapid is the reaction of the vessels.—*Annali Universali di Medicina e Chirurgia, parite revista*, September, 1885.

TUBERCULOUS MENINGITIS SUBSEQUENT TO SURGICAL OPERATION FOR REMOVAL OF FUNGOUS SYNOVITIS.—At a meeting of the Société de Chirurgie, held October 21, 1885, M. RICHELOT reported the history of a case of tubercular meningitis, supervening upon an operation for fungous synovitis of the wrist. The operation was performed August 3d, and consisted simply of scraping the fungosities developed in the sheath of the flexor muscles of the wrist. The wound was dressed antiseptically, and united by first intention. The patient was a vigorous, well-developed man, whose general condition gave no indication of tubercular diathesis—but the day succeeding the operation the temperature rose to 102.2° F., and subsequently varied between this and 104° and 105.8°. August 15th, violent pain was experienced in the testicles and a double orchitis was developed, and at the same time symptoms of meningitis came on, to which the patient rapidly succumbed. The autopsy showed, in addition to the meningitis, the presence of gray granulations in the lungs, together with the reappearance of the fungous growths in the wrist.

M. Richelot considers the case beyond doubt as one in which surgical operation produced a general from a local tuberculosis.—*L' Union Médicale*, Oct. 27, 1885.

PATHOLOGY OF HEMICRANIA.—PROFESSOR VIZIOLI (*Giornale di Neuropatologia*, Fas. 1 and 2, 1885), in opposition to the views held by some writers concerning the pathology of hemicrania, holds that the seat of origin of the disease must be the cervical sympathetic nerve.

Further, no inguinal neuralgia is accompanied by symptoms of derangement of the function of the sympathetic by the agency of the ganglionic chain, as shown by nausea, vomiting, etc., conditions always peculiar to hemicrania. Still further, the relationship of hemicrania and epilepsy, maintained by Möbeus, is denied by Professor Vizioli.—*Rivista Internazionale di Medicina e Chirurgia*, September, 1885.

SUPRAPUBIC LITHOTOMY FOR THE REMOVAL OF A VESICO-URETHRAL CALCULUS; DEATH FROM PYELONEPHRITIS EXISTING PREVIOUS TO THE OPERATION—DR. LOUMESA (*Journal de Médecine de Bordeaux*, September 20, 1885) reports the case of a young man, aged twenty-six years, in whom incontinence of urine was present for a long time, and in whom latterly the urine became purulent.

At examination made at the hospital the sound was found to be arrested in the membranous portion of the

Digitized by Google

urethra by a rough immobile body, which was continuous with a much larger calculus in the bladder—the dimensions and exact situation of which could be accurately determined by rectal examination.

The stone was evidently as large as a hen's egg, and, besides occupying the bladder, was prolonged into the deep portions of the urethra.

Suprapubic lithotomy was performed in the usual manner, according to Petersen's method. After the operation Périer's tubes were introduced, and the bladder washed out every four hours.

Death of the patient on the day succeeding the operation.

Post-mortem examination showed the presence of marked cystitis. The urethra exhibited no lesions save extreme redness and some slight ulceration in its membranous portion. The ureters were much dilated and tortuous, especially the left, which had a calibre equal to the small intestine, and was distended by a thick inflammatory pus, mingled with fine débris of uric acid concretions. The left kidney was considerably hypertrophied, and its entire parenchyma studded with purulent cavities the size of a cherry, and occupying especially the medullary substance. The pelvis and calices were also distended with pus. On the right side the lesions were less advanced.

The calculus was of the size and shape of a large egg, one of its extremities, tapering, sent a conical prolongasion into the deep urethra. The composition of the calculus was found to be uric acid in the centre, and phosphate of lime on the periphery.—*Annales des Maladies des Organes Génito-Urinaires*, November 1, 1885.

DANGERS OF COCAINE IN OPHTHALMIC PRACTICE.—At a late meeting of the Ophthalmological Society of the United Kingdom (*British Med. Journal*, November 21, 1885), MR. NETTLESHIP inquired whether there was any general suspicion that the gelatine disks of cocaine were not satisfactory? His suspicions had been raised by the occurrence of a serious run of cases of panophthalmitis at St. Thomas's Hospital, while, at the same time, the cases at Moorfields did well. At St. Thomas's Hospital he had been using gelatine disks of cocaine before iridectomy and cataract. Messrs. Savory and Moore had informed him that, since cocaine was hygroscopic, the gelatine disks were always moist, and that it was impossible to keep them thoroughly dry; he suggested that the disks might afford a breeding ground for pathogenic organisms. Solutions of cocaine also apparently had a tendency to cause panophthalmitis. Gräfe had found chronic interstitial keratitis much more common since he had used cocaine.

MR. M. MCHARDY had also, at one time, had a run of panophthalmitis after using solutions of cocaine. Fifteen days appeared to be the longest time which it was safe to keep a solution of cocaine; since using quite fresh solutions (eight per cent.) he had had no bad cases.

MR. EDGAR BROWNE had also recently had an unfortunate series of cases, and was inclined to suspect that cocaine was responsible for that misfortune.

MR. STORY said that solutions of cocaine might be made up with boracic acid. He observed that he found it difficult to understand why solutions of cocaine should be so dangerous, while atropine solutions had been used for many years without mischance. He observed that epidemics of panophthalmitis had always occurred from time to time before the introduction of cocaine.

MR. MARCUS GUNN suggested that these epidemics might have been due to the atropine solutions, which had also afforded a breeding-ground for germs.

MR. LANG mentioned a case of panophthalmitis which he had recently encountered, where the only cause that could be suggested was that the solution of cocaine was not fresh.

MR. NETTLESHIP said that, at Moorfields, the solutions of cocaine were made up with saturated solution of boracic acid. He had never before had so severe a run of cases in his own practice.

LACTIC ACID AND TUBERCULAR LARYNGITIS.—A discussion has taken place in the Berlin Medical Society on the value of lactic acid in laryngeal tuberculosis. DR. KRAUSE stated that, of fourteen undoubted cases he had treated in this way, some were improved, and some completely cured. The least satisfactory cases were those where the posterior wall of the larynx was affected; also those where there was a lesion below the vocal cords which could not be well brought under the influence of the application. The voice improved, also the power of swallowing, and the general condition of the patients. DR. ROSENBERG confirmed the statements of Dr. Krause as to the good effects of lactic acid, but, for his own part, was still more satisfied with the results of a twenty per cent. solution of menthol. He was also treating pulmonary phthisis with menthol inhalations. DR. LUBLINSKI had had a certain amount of success with lactic acid, but found that, after the ulcers had healed, they again broke out. PROFESSOR VIRCHOW pointed out that when these ulcerations healed, a cicatrix only was formed, not true mucous membrane. He hoped that further observations on this subject might be made, especially on cases that had healed for some time.—*British Med. Journal*, November 21, 1885.

COCAINE IN SEASICKNESS.—DR. WICHERKIEWICZ has been making trial of Professor Manassein's remedy for seasickness—cocaine—and confirms the St. Petersburg professor's high opinion of its value. Dr. Wicherkiewicz employed it chiefly in children, giving from 0.03 to 0.05 gramme (from half to three-quarters of a grain) in a one per cent. solution. He finds that cocaine acts not only by diminishing the impression made on the terminal nerves in the abdomen, but by allaying the irritability of the nervous centres. The best plan is to give cocaine at the very commencement of the voyage, for after vomiting has commenced the power of the drug over the affection is diminished. The dose should be repeated every two or three hours. It is best to use a solution of the strength of from two to five per cent., which, in order to obviate any unpleasant effects on the throat, should be enclosed in amylaceous capsules.—*The Lancet*, Nov. 14, 1885.

THE ACTION OF MERCURY UPON THE BLOOD.—DR. L. GALLARD, in an experimental study to determine the action of mercury upon the blood, concludes:

1. That the number of the red corpuscles may diminish slightly at the beginning of the administration without

Digitized by Google

regaining their original proportion, but more frequently it increases progressively, until about the fourteenth day of treatment, to undergo at this time a slight diminution.

2. The hæmoglobin always increases progressively until about the twenty-fourth day of treatment, and having attained at this time its greatest abundance descends to its original proportion, and if the treatment is continued sinks below it.

3. The abundance of hæmoglobin increases in a proportion beyond that of the red corpuscles, and may even increase when these diminish, whereby mercury may be compared to those metals which induce the production of hæmoglobin.

4. The weight of the body increases almost constantly, though it is impossible to determine the exact relation which exists between such increase and the condition of the blood.—*Archives Générales de Médecine*, Nov. 1885.

THE THICKNESS OF THE CEREBRAL CORTEX IN MAN.—GIACOMINI (*Giornale della R. Academia di Med. di Torino*) gives the result of his microscopic investigations to determine the thickness of the cortical substance of the brain in man. He finds that it varies at different periods of life, and also according to its location.

The investigations were made upon fresh brains, deprived of their meninges.

The cortex was found to diminish in thickness at all points of the cerebral substance with increased age. In the pre-Rolandic region, in youths the thickness of the cortex is greatest at the internal face, but in adults and the aged at the external face.

The thickness of the cortex, which limits the fissure of Rolando, is greatest at the anterior parietes, least at the posterior.

The maximum thickness of the cerebral cortex is met in the region of Rolando precisely at the apex and walls of the ascending frontal convolution.

With regard to sex, the development follows the same laws; and in reference to age there are divers points of variation in the same brain.—*Annali Universali di Medicina e Chirurgia, parte revista*, September, 1885.

SANTONINE IN AMENORRHŒA AND DYSMENORRHŒA.—DR. J. CHÉRON recommends the use of santonine in cases of amenorrhœa and dysmenorrhœa, particularly in connection with adynamia, during the period which succeeds the more or less incomplete establishment of the menses at puberty.

The action of the drug is considered to be comparable to that of ergot, and in cases of chronic congestion, which produces amenorrhœa and dysmenorrhœa in the debilitated, its good results seem to be due both to its local and general tonic effects.—*Revue de Thérapeutique*, November 1, 1885.

ANIMAL HEAT DURING CONFINEMENT.—At a recent meeting of the Academie des Sciences, M. BONNAL reported the results of his observations taken to determine the temperature of both women and children at the moment of birth. His conclusions are the following:

1. Labor does not always appreciably elevate the temperature of the parturient woman.

2. Elevation of temperature after confinement is in relation neither with the duration of labor, the intensity of the pains, the age of the woman, nor with the time intervening between the rupture of the membranes and the birth of the child.

3. The temperature is not more elevated in primiparæ and in twin labors nor in breech and face presentations when there is no disproportion between the size of the child and the parturient passages.

4. Compared with that of the mother, the rectal temperature of the child at the moment of its birth is exceptionally below, rarely equals, and is almost always higher by about $\frac{1}{8}$ to $1\frac{1}{4}$° F.

CONNECTION BETWEEN AFFECTIONS OF THE EYE AND SPINAL CURVATURE.—DR. JASINSKI, a Polish physician, has traced a connection between errors of refraction and curvatures of the spine. In thirty-seven cases of curvature he was able to prove with certainty the previous existence of these or other abnormal conditions in the eyes, such as insufficiency of the internal rectus, astigmatism, asthenopia, etc. Myopia alone, however, does not appear to cause curvature. Unequal vision and insufficiency of the internal recti seem to be most efficient in the production of spinal curvature. Spasm of the accommodation also is capable of producing it. Removal or relief of the eye affection is followed by improvement in the spinal curvature—a troublesome and obstinate class of cases in orthopedic practice.—*The Lancet*, Nov. 14, 1885.

THE QUANTITY OF BACILLI IN THE EXPECTORATION OF CONSUMPTIVES.—DT. ZENKEWITCH, *Revue de Médecine*, as the result of fifty-one observations made in the clinic of Professor Mering, of Kiel, has determined:

1. That the quantity and quality of the expectoration have no influence upon the quantity of bacilli.

2. The statistics given by Balmer, Fraentzel, and Pfeiffer, to show that during the last days of life of the patient, the quantity of bacilli attains a maximum, are far from being exact.

3. The amount of bacilli in the expectoration does not depend upon the extent of the pulmonary disease.

4. It is proportional to the degree of fever, which depends also upon the rapidity of the destructive lesions of the disease.

5. Bacilli do not have their origin in the expectoration, whence they penetrate into the pulmonary tissue, but the contrary fact obtains. The statement that they develop mostly in the pulmonary parenchyma (Balmer and Fraentzel) is at least very doubtful.—*Journal de Médecine de Paris*, November 1, 1885.

TUMORS OF THE BLADDER.—DR. GIOVANNI MORI, in a study of tumors of the bladder, agrees with Pousson, in affirming:

1. The benign tumors of the bladder, papillomata, are more frequent than malignant neoplasms.

2. The favorite seat of these and other new growths is the back and posterior wall of the bladder.

3. They all have a tendency to be small.

4. Ganglionic engorgement and general infection are extremely rare.

5. Inflammatory lesions of the bladder and kidneys are slow, and are only exceptionally the direct consequence of the neoplasm, unless at a late period, when provoked by catheterization or ill-advised treatment.—*Annali Universali di Medicina e Chirurgia*, September, 1885.

COCAINE IN WHOOPING-COUGH.—DR. PRIOR, of Bonn (*Berliner klinische Wochenschrift*), has treated several cases of whooping-cough with cocaine, with good results. As is evident on *a priori* grounds, he does not consider the drug a specific, but simply a means of relieving and reducing the number of the paroxysms. He used fifteen and twenty per cent. solutions to paint the fauces, the interarytenoid fossa, and the vocal cords, with the result of prolonging the interval between the attacks, and lessening the severity of these. The treatment was resorted to twice daily, great stress being laid on the necessity of producing at the time complete anæsthesia of the fauces and upper part of the larynx. Inhalation of a twenty per cent. solution four times a day was not so successful as painting.—*British Med. Journal*, November 21, 1885.

HABITUAL ABORTION AND KIDNEY DISEASE.—At the recent meeting of German scientists and medical men at Strasburg, Dr. Fehling, of Stuttgart, read a memoir on habitual death of the embryo in kidney disease. In the first case under his observation, premature expulsion of a dead fœtus occurred six times, and there was no evidence of syphilis. At every pregnancy, anasarca, albuminuria, and death of the fœtus, with severe cramp of the abdominal muscles, occurred, between the fifth and sixth month; the dead fœtus was expelled from three to ten weeks later. In the second case, similar symptoms appeared in a young unipara; the fœtus died, and thereupon the albuminuria abated. In the third case, the patient had borne two healthy children. During her third pregnancy, albuminuria and characteristic changes in the retina occurred; and, during the fourth, she was seized with hemiplegia; in both, a decomposed fœtus was expelled at the fifth month, with subsequent decrease of the albuminuria. In the fourth case, the patient, in her first pregnancy, aborted at the fifth month; then she gave birth at term to a recently dead child. In the third pregnancy, great œdema and albuminuria supervened, the child was stillborn, and the mother died of uræmia. Dr. Fehling believed that, in all these cases, kidney disease existed before pregnancy, which aggravated the renal symptoms. Winter had described two cases of premature detachment of the placenta, normally situated, where albuminuria existed. Dr. Fehling found atrophy of the villi of the chorion, with wedge-shaped or spherical infarcts in the placenta, in his cases, similar to renal infarcts. The infiltration of the chorionic villi and vessels of the umbilical cord with small cells, as seen in syphilis, was absent, nor did any of the embryo exhibit a trace of congenital syphilis.—*British Medical Journal*, November 21, 1885.

TOXIC ACTION OF COCAINE.—DR. ZIEM, of Dantzic, has communicated to the *Allgemeine medicinische Central Zeitung* the notes of a case, in which he applied two drops of a four per cent. solution of cocaine to the eye of a man, aged 40. In a few minutes, after the pupils had become dilated, the patient's face became pale, sweat broke out on his forehead, and his breathing became embarrassed. Dr. Ziem at once loosened his clothes and opened the window, but it was a quarter of an hour before he could return home. The man's wife said that he had not previously had syncope. He was of intemperate habits, and some years ago had been treated for disturbances of motor power in the lower limbs, apparently connected with syphilis. Dr. Ziem says that seventeen cases have been recorded in ophthalmological literature in which toxic effects followed the use of cocaine. In three it was injected hypodermically, and in fourteen dropped into the conjunctival sac. The cases have been described by Peck (1), Mayerhausen (1), Stevens (1), Reich (2), Knapp (3), Heuse (4), and Bellarminoff (5). In some cases the symptoms have been transient, consisting of pallor of the face, giddiness, and sweating of the face or neck; in others there have been dyspnœa, great feeling of prostration, malaise, and apathy, lasting sometimes for several days. Vomiting and headache have been rarely present. In one case, the application of fifteen drops of a two per cent. solution to the conjunctiva was followed by tottering gait, difficulty of speech, confusion of the mind, and extraordinary restlessness; and, in another, the subconjunctival injection of about eight drops of a 3.5 per cent. solution produced convulsions and loss of consciousness. The strength of the solution used was 4 per cent. in eight cases, 2.5 per cent. in four, and 2 per cent. in three or four others. The quantity generally varied from two to four drops. The subjects were, in some cases, feeble, aged women; in others, they were strong and healthy individuals, both male and female.—*British Medical Journal*, November 21, 1885.

TUBERCULAR MENINGITIS CURED BY IODOFORM.—A Swedish physician, Dr. Emil Nilsson, alleges that he has cured an undoubted case of tubercular meningitis by frictions on the shaved scalp with iodoform ointment (1 to 10). The patient was a boy, aged 8, whose mother had a family history of phthisis, and four of whose brothers and sisters had died from tubercular meningitis. The symptoms in this child's case were similar to theirs—headache, torpor, convulsions, strabismus, and pyrexia. He was at first treated with calomel and iodide of potassium, but did not improve; and, after having been under treatment a week, became distinctly worse, being unable to take food or medicine. The pallor of the face, which had preëxisted, gave way to flushes of the cheeks. The child threw himself out of bed, and presented severe clonic spasms of the limbs and of the facial muscles. The head was then shaved, and iodoform ointment rubbed in, an oil-skin cap being put on. The friction was repeated three or four times in the day, and the next day there was a decrease in the convulsive movements, the sleep was calmer, and the spasmodic contractions, which had previously been excited by the slightest noise, now ceased to be so. Consciousness shortly afterward returned, and the child's face became of a more natural color. This, however, was accompanied by a severe coryza, redness of the lips, and an irritable cough, the breath smelling strongly of iodoform. The ointment was discontinued, and syrup of iodide of iron given. The unpleasant symptoms rapidly disappeared, and the child was soon running about in good health.—*British Medical Journal*, November 21, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, DECEMBER 5, 1885.

EXTIRPATION OF MALIGNANT TUMORS OF THE SKULL.

THE past few years have witnessed a great deal of activity in the study of the surgical treatment of diseases and injuries of the skull; and the increased confidence secured by the success of antiseptic methods of operating, has led to a revival in this field of surgery not unlike that which took place at the beginning of the last century, under the stimulus of the prizes offered by the Academy of Surgery of Paris. In this country, DR. JOHN B. ROBERTS has attracted renewed attention to the question of freely attacking the cranium, under circumstances which to many others do not appear to require such intervention; while in Germany, WIESMANN has followed a number of careful students of injuries of the head, among whom VON BRUNS and VON BERGMANN are conspicuous, with an elaborate study of the modern indications for the use of the trephine.

In this admirable article, contained in the *Deutsche Zeitschr. f. Chirurgie*, Bd. xxi. and xxii., 1885, there is a summary of a number of cases of the removal of tumors involving the bone, with a detailed account of one operation by Krönlein, and a strong recommendation of this procedure based upon the cases cited. Krönlein's patient was a woman of middle age, who had a carcinoma of the forehead, which had been excised thrice, and burnt out with caustics twice. After this she came, in 1881, under the care of Krönlein, having on her forehead an ulcer 2½ inches wide, extending from the root of the nose beyond the line of the hair. In the centre the bone was bare. Under antiseptic precautions, Krönlein extirpated the whole growth, with a piece of the bone and of the dura mater as large as a five dollar gold piece, as well as nearly half an inch of the falx cerebri. The wound was washed out with carbolized water, and dressed with carbolized gauze and salicylated cotton. The result was only fair. In two months a small secondary growth had to be removed with the Paquelin cautery knife. Hernia cerebri soon occurred, and was followed by brain symptoms, vomiting, paralysis, and death three months after the operation. The autopsy showed the existence of meningitis and encephalitis.

A more fortunate termination occurred in a case of GUSSENBAUER, which he describes in the *Prager Zeitschrift f. Heilkunde*, 1884, Bd. V. His patient was a man, 25 years old, who had a sarcoma of the frontal bone, for the cure of which a flap as large as half the forehead was turned up, and the bone cleared away with chisel and forceps, over a space about 3 by 3½ inches. The dura was not cut, although the tumor had to be cut loose from it at one point. The wound healed promptly under antiseptic dressings, and two years afterward there had been no return of growth.

PAULLY, also, has recently reported a successful operation of this sort in the *Verhandlungen der d. Ges. f. Chirurgie*, 1883. His patient was likewise a man, 26 years old, who had a fibrous sarcoma of the forehead. He was subjected to an operation in March, 1882, in which the bone was chiselled out to a moderate extent, and the tumor was separated from the dura. The wound granulated nicely, but the new growth returned in the outer part of it in about two months. At this time it was scraped out with the sharp spoon, and a plastic operation was done to cure an ectropion which had appeared. A third operation was required for recurrence after the lapse of six months, and the frontal bone was removed from the root of the nose to the zygoma, and up to the hair line. In a month the wound was quite well healed, and about five months afterward the patient was shown to the Congress of German surgeons, with the cicatrix complete, but with an ectopion, and an enlarged gland behind the angle of the jaw—whether connected with the growth or not, was not known.

These three operations, with one done by Volkmann, in 1875 (in which the longitudinal sinus was accidentally divided, air entered it, and the patient died promptly), may be taken as fair representatives of the procedure we are considering, illustrating every possible termination of it, from immediate death to apparently complete cure.

A review of the history of operations of this sort, shows that they are not altogether novel. The earliest records of surgery contain accounts of operations of trepanning for fungous tumors of the dura

Digitized by Google

mater. Most of these accounts are not very instructive, because it is not clear whether the writers referred to new growths, or simply to hernial protrusions of the brain, the probabilities being generally in favor of the latter. But, as early as the seventeenth century there are unmistakable records of such operations as we are discussing. Sand has recorded in *Halleri Disput. Chirurgie, select.*, Vol. I., an operation done in 1696, in which by trephining at intervals and removing the intervening bone, an aperture 6½ inches in circumference was made at the junction of the sagittal and coronal sutures; after which, whatever fungous growth there was, seems to have been removed piecemeal with the dressings. In 1757, Volprecht reported to the French Academy of Surgery a case in which, two years before, an attempt to remove a fungus of the occipital region had been begun, by trephining to one-third of the extent of the circumference of the tumor, and then abandoned, because to continue would have necessitated passing across the occipital protuberance, and, it was feared, wounding the sinuses under it. The autopsy showed that this fear would not have been realized, as the bloodvessels had been pushed away by the tumor; but there was also a new growth at the base of the skull, which would have frustrated the hopes of the operators.

This case was cited among others, by Louis, in his article "Tumeurs fongeuses de la Dure-Mère" in the *Mémoires de l'Ac. Royale de Chirurgie*, 1774, which he recommends, in the case of what was then known as fungus of this membrane, but which was probably often sarcoma, early opening of the dura mater. In 1816, Baron Boyer, influenced, possibly, by the views of Louis, urged operation for fungous tumors of the dura.

The first surgeon to put these courageous suggestions into practice, as far as we know, was Bérard, who, in 1833, published in the *Gazette méd. de Paris*, p. 735, an account of a case in which he removed a recurrent fungus of the vault of the cranium as large as a fist, by making 16 openings with the trephine, on two successive days, and clearing away parts of both parietals, and of the frontal, temporal, and sphenoid bones, covering an extent of 5 by 4½ inches. The dura mater was also cut out, with a piece of the falx and longitudinal sinus. The patient died in 34 hours. In considering this result, it must be remembered that these operations were done without anæsthesia.

The next operation to which we have access, was done by Volkmann, in 1875, and to which we have made reference in the earlier portion of this article. After this comes a list of operators, almost exclusively German, including the names of von Bergmann, Novaro, von Langenbeck, Czerny, Küster, Krönlein, Gussenbauer and Paully, who, stimulated by the increasing number of recoveries after the operation, added to the total number thirteen cases in the four years from 1879 to 1882.

In looking over the cases reported with sufficient detail to make them valuable for analysis, we find only 15 done since the adoption of antiseptic methods. Of these, 13 recovered from the operation, and 2 died, one being the patient of Volkmann, and the other that of Krönlein, already mentioned. As to sex, 3 were male, 10 were female, and the sex of 2 is not given. The youngest patient was 19 years old, and the oldest 64; the average age was 44 years. In eight cases the dura was cut into or cut away; the falx was cut four times; the longitudinal sinus was divided twice; and some brain tissue was removed twice; but in no case, except that of Volkmann, was this complication followed by the death of the patient. The extent of bone removed was in all cases considerable, and in some very great. In five cases it was over three inches across. The character of the tumor in these cases was: Myxoma, 1; carcinoma, 2; epithelioma, 1; cancroid, 2 (both in same patient); mixed connective tissue, 2 (both in same patient); and sarcoma, 7 (2 in one patient).

The 15 operations were done on 12 patients, in 10 of whom the tumor occupied the frontal region; in 1 it is said to have been on the side of the head; and in 1 the location is not given. In only 1 of the 15 operations did recurrence take place before the healing of the wound; and speedy recurrence took place in only 4 cases.

The operations were all done, as is stated or fairly presumable, with strict antiseptic precautions. After some of them union of the wound took place by first intention, and in almost all with great promptness.

With this we must leave the subject, simply remarking that such a showing seems to justify the warm approval which this operation has been meeting with in Germany of late, notwithstanding that it is diametrically opposed to what is found in most of the modern works on surgery in the English language.

THE CAUSES OF SUDDEN DEATH.

FROM year to year, the mariners as they passed to and fro saw no change in the Hell Gate rock at low tide, yet there had been unseen forces at work quietly undermining the rock and preparing for its destruction, which came at last suddenly, effected by the touch of a child's hand. So, too, may a man present no outward change, and go about his business as usual, showing neither to himself nor to his most intimate friends any evidence of the secret processes at work within him, and yet the end may come as an explosion, startling in its terrible suddenness.

Theoretically, the animal machine should be constructed like the Deacon's "One-hoss-shay," each

Digitized by Google

component of equal strength and durability, and no one should be the first to wear out, but all should go together. We occasionally see this, not often it is true, but it does occur; the organism gradually wears out in old age, all parts go together, and we cannot say that any one gave way first. This is Bichat's natural death. Few reach it; for the majority, death ends a struggle with evident disease, often painful, tedious, and prolonged. But it may come without any warning, and strike down the active, vigorous man in the apparent possession of full powers and faculties. Nothing is truer in the matter of health, than that "the outward shows may be least themselves." So insidiously may the processes of disease work in the system, that, like the rock, the constitution may be seriously undermined, and present very little external evidence of the deep-seated changes, which only await some slight disturbance—the touch of a child's hand—to cause destruction.

The weak link in the chain, to change the simile, is the one to snap, and in a man with an average constitution, living an active public life, the weak link is apt to be the one upon which the greatest strain is constantly thrown. It is not difficult to show that in the labor of life the circulatory system bears the brunt of the strain, and is the one which has to meet every extra call or demand on the part of the body, and we consequently find that in a sudden break-down of the vital machinery this is the part which has usually given way. The cases of very rapid death are almost always due to affections of the heart, or of the great vessels. Inhibition from shock may stop a normal heart, but commonly when there is sudden cardiac failure, the organ has been more or less diseased. Fatty degeneration, extensive disease of the coronary arteries, and insufficiency of the aortic valves, are conditions of the heart itself most often met with in these cases. In the first of these it may occur without any preliminary symptoms.

Aneurism of the aorta is responsible for a very considerable proportion of all cases of sudden death, and it is surprising how frequently the condition is unsuspected. Associated with chronic vascular changes, especially in the smaller vessels, we find degeneration of the kidneys and hypertrophy of the left ventricle of the heart. This triple combination forms the chief anatomical features in chronic Bright's disease, an affection often latent, which certainly seems to be on the increase, and which brings with it special perils, of which apoplexy is the most serious. In nine of ten deaths from brain disease, the lesion is vascular, but, except in large hemorrhages or when the medulla is directly involved, the death is rarely instantaneous. Sudden, unexpected death from paralysis of the respiratory centre is not common apart from vascular changes.

The recent death of Vice-President Hendricks, although sudden, could not have been entirely unexpected to his intimate friends, for he had, within the past five years, two attacks which indicated serious degeneration in his circulatory system. Four years ago he had a slight hemiplegia, from which he recovered completely, and about 1883 he had gangrene of the foot, which got well with the loss of a toe. After two such knocks, we do not wonder that death should burst in the door without further parley. The details of his last illness are rather meagre, but he appears to have returned from Chicago with a heavy cold, for which he kept his room and bed. The actual cause of the abrupt termination of the illness is, in the absence of a post-mortem, a matter of conjecture, but, in the light of the history of his previous attacks we may reasonably attribute it to heart failure or paralysis, possibly from fatty disease or arterial break-down.

In the case of a man like Mr. Hendricks, whose work was not completed, we may regard sudden death as a calamity, but it is not so in all cases. Better the sharp, quick stroke which at once ends all, than to lose by a gradual process of disintegration those faculties of mind and body which make life supportable, and creeping at a slow pace along the way to dusty death finally to reach a condition which may be truly described as "*ita sine vitâ vivere; ita sine morte mori.*"

REPORT OF THE ENGLISH CHOLERA COMMISSION.

FROM abstracts which have appeared of the report issued by the India Office in London, we gather that DRS. KLEIN and GIBBES have not receded from their original position, but maintain the innocuous character of the comma-bacillus of Koch. While it is allowed that the comma-shaped bacillus of the mouth, observed by Lewis, and the bacillus of cholera nostras, described by Prior and Finkler, are not identical with Koch's organism, yet their occurrence is held to do away with the diagnostic value of the latter. Other organisms are stated to grow on culture media in a way very similar to Koch's bacillus, though it is admitted that the gelatine cultures of the bacillus found in cholera nostras differ in an unmistakable way. The second point on which they differ from Koch, is the prevalence of the bacilli in the intestines, for in their experience these organisms may be, in typical cases, very scarce, and it was found that the longer the examination was delayed or the longer the patient was *in articulo*, the greater the number of bacilli present in the intestines. A peculiar, short, straight microbe was present in many cases, but it, with the comma-form, was regarded "as something extraneous, present only in tissues practically dead in the cavity of the alimentary canal." The third point relates to the artificial pro-

Digitized by Google

duction of the disease. The results of the experiments were uniformly negative.

The conclusion they have reached is that the intestines do not contain the cholera poison in the shape of an organism, but that the virus is produced outside and independently of the body of the cholera patient, and is of the nature of a chemical or non-organized ferment.

This report practically reopens the whole question, and the points at issue must be decided by independent and competent observers. Dr. Watson Cheyne's suggestion of a commission would certainly now be in order; meanwhile, we shall await with interest the results of the study of the disease by the American Commissioner, Dr. Shakespeare.

SANITARY CERTIFICATES.

A WRITER in *The Sanitary Record* tells us that, in looking through a boarding-house at Ramsgate, he found, hanging against the wall of the hall, a printed certificate, signed by the Medical Officer of Health and by the Surveyor of the Improvement Commissioners, stating the results of a sanitary examination of the premises: it was to the effect that the drains of the house were efficiently trapped and ventilated; that the water-supply was derived from the mains, was abundant, and ran no risk of being contaminated; and that the premises generally were in a wholesome and good sanitary condition. This is a practical exemplification of the idea that a party proposing to occupy a house has a right to information relating to its sanitary arrangements. He is unable to gather this knowledge from a personal examination, and, if he depends on the agent or landlord, he may or may not be correctly advised. An authorized and reliable certification of the sanitary condition of the premises will settle the doubt.

No house should be allowed to be licensed as a boarding-house or as a hotel without a sanitary certificate based on a record of facts. It is a question whether such a condition can be legally imposed. If it cannot be enforced by legal enactment, it can and should be made obligatory by the pressure of popular sentiment and demand, which often indirectly accomplish what the law directly fails to secure. If the public avoid such houses as are not certified, by competent authority, as having proper sanitary arrangements, the owners of such houses will be compelled to apply for the necessary record, which is tantamount to a request for a thorough sanitary inspection and the adjustment of the arrangements of the house to the standard of the regulations upon which a sanitary certificate must be based. If anyone fails to demand a certificate and exposes his own health and that of his family to risk, he will only have himself to blame.

There is a wider application of this subject, which is worthy of thoughtful consideration. A thoroughly organized and efficient health department ought to be able to furnish, from the records, a sanitary history of every house in the town or district. By a careful sanitary survey, it is possible to place on record a brief description of every dwelling, showing the plan and character of the drainage arrangements, the location and character of the cesspools, the conditions of the soil, the nature of the water-supply, the number and causes of deaths which have occurred in the house and in the square in which it is located, etc. Such a record could be kept up without great labor, and would be invaluable for the information and safety of the persons proposing to rent or buy and occupy a house. The record of title is not more important in its way than a certified copy of the sanitary history of the premises is from a health standpoint. The neglect of the former may involve loss of property, but the neglect of the latter may result in loss of health, it may be of life.

REVIEWS.

VON ZIEMSSEN'S HANDBOOK OF GENERAL THERAPEUTICS, IN SEVEN VOLUMES. Vol. I. DIETARY OF THE SICK. Vol. II. METHODS OF TREATMENT. Vol. III. RESPIRATORY THERAPEUTICS. New York: William Wood & Co., 1885.

THIS work, which was in process of publication in Germany for about four years, was concluded in 1883 by the issue of what forms the first volume of the English translation. Attached to this is a general introduction and conclusion to the Handbooks of General Therapeutics and of Special Pathology and Therapeutics (Ziemssen's Encyclopedia), in which the editor tells us that the original intention was for the work on therapeutics to form part of, and supplement, the larger handbook. And now, on the completion of the programme, he discusses the question whether any serious objection can be taken to it, either from a theoretical or practical standpoint. The rapid progress of the past decennium has rendered necessary a critical mustering and inspection of our gains, that we may know what and how much we may register as the certain property of science. To do this effectively, a division of labor was essential, and "fundamentally revisional works of this kind in the hands of eminent specialists, become mines rich in ideas and springs of manifold encouragement to fresh work." He acknowledges that the work is not free from the defects inseparable from multiple authorship, but "so long as the most important principles of the science are contested and the struggle of opinion sways to and fro, so long it can do no harm if the strife of theories makes itself apparent in a work that professes to reflect the existing state of science." That the work has attained its aim, is attested by the tokens of kindly acknowledgment which have come from all branches of the profession, and he lays special stress on the impartial judgment of the foreign press.

Volume I. is a complete text-book of *Dietetics*, from the pen of Professor Bauer, of Munich, with a supple-

Digitized by Google

ment on the *Koumiss Cure*, by Dr. Stange, of St. Petersburg. The translation is by Edward F. Willoughby, M.B. An idea of the scope of the work may be obtained from the following headings of sections: Aims of Dietetics in Disease, The Value of the Several Foodstuffs, Preparation and Cooking of Food, Digestion and Utilization of Nutriment, The Demand of the Organism for Nutriment, Special Dietetics for the Sick, Dietetic Modes of Treatment.

We do not know any other work of the kind dealing so thoroughly with these questions.

Volume II. comprises *Antipyretic Methods of Treatment*, by Professor Liebermeister; *Antiphlogistic Methods of Treatment*, by Professor Jürgensen; *Epidermic, Endermic, and Hypodermic Administration of Medicines*, by Professor A. Eulenberg. The translation is by Professor Matthew Hay, of Aberdeen, who has added a few notes and to the end of the volume a short section on certain new antipyretic medicines, rendered necessary from the fact that the original appeared in 1880. The section in antipyretics contains four chapters: I. Abstraction of Heat; II. Antipyretic Medicines; III. Antipyretic Dietetics; and IV. Application and Results. The antiphlogistic methods of treatment and the two subdivisions on bloodletting and transfusion are most elaborately considered by Dr. Jürgensen. In the concluding section there is a full discussion upon the various modes of introducing medicines into the body through the skin.

Vol. III., devoted entirely to *Respiratory Therapeutics*, is by Professor Oertel, of Munich, and is translated with a preface and notes by Professor J. Burney Yeo, of Kings College, London. This forms the largest volume of its series and is, as Dr. Yeo says, "a timely and unmistakable testimony of the importance which is attached in Germany, at any rate, to the methods therein described, of treating the diseases of the respiratory organs." It is a manual upon the use of inhalations and the pneumatic methods.

The departments of therapeutics which Prof. Oertel deals with in this exhaustive manual, have certainly not received from the profession in this country the attention they deserve, and it is to be hoped that a careful study of his work will do much toward removing the prejudice against certain of these methods, which the extensive experience of French and German physicians has found to be of signal benefit in suitable cases.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, November 10, 1885.

THE PRESIDENT, ROBERT F. WEIR, M.D., IN THE CHAIR.

NEURALGIA OF THE SUPERIOR MAXILLARY AND INFERIOR DENTAL NERVES; RESECTION; CURE.

DR. WILLIAM T. BULL presented a man showing the results of two operations, one performed upon the superior maxillary and the other upon the inferior dental nerve for obstinate neuralgia. These operations were performed fifteen months ago, and there had been no return of the trouble whatever, and he thought the case might be regarded as one of cure.

A night watchman, sixty-two years of age, was admitted to the New York Hospital, July 29, 1882. For several years he had had, at intervals, some pain in the right side of the face, which, within a year, had become more severe and almost continuous. He was rheumatic. had not had syphilis, and the history of malaria was doubtful. All sorts of medical treatment had been resorted to, and many teeth, in both the upper and the lower jaw, had been extracted.

When admitted he was suffering from the same pain, which was partly controlled by hypodermic injections of morphine. There were tender points over the infra-orbital and mental foramina, and over the condyle of the jaw. He was slightly emaciated, and could not eat solid food, and also had pain in talking.

Aug. 11, 1884. The superior maxillary was exposed in the floor of the orbit, and three-fourths of an inch removed. The artery was divided, and bled sharply. It was stopped by a plug of catgut, which was continuous with a few strands emerging from the centre of the wound. Peat and bichloride dressing. The wound healed primarily in four days.

Aug. 18. The inferior dental nerve was exposed by a vertical incision over the ramus of the jaw, and chiselling through the outer wall of its canal (Warren's operation). The incision was placed low enough to avoid Steno's duct, the fibres of the masseter with the periosteum were raised with the elevator, and the upper angle of the wound strongly retracted. It was a narrow wound to work in, but there was little difficulty in removing a rectangular piece of bone, whose dimensions were one-fourth by three-fourths of an inch. Three-quarters of an inch of the nerve were removed. In separating it from the artery the latter was wounded and tied with catgut. A small bone drain was left in the wound, which was treated like the other. At the end of a week, when the dressing was removed, the wound had healed except at the orifice of the tube, and this closed promptly under an iodoform scab.

From the time of the operation the man experienced no pain whatever in the face, and there was complete anæsthesia over the areas supplied by the nerves. There was no facial paralysis.

Now, fifteen months after the operation, he continues perfectly well. There has been a dull aching in the lower jaw in damp weather, but it is trifling in degree, and does not increase in either frequency or severity.

DR. R. H. AMIDON kindly examined the man lately, and stated: "I tested the sensibility with a faradic current and a single wire electrode, and found complete anæsthesia on the right side of the face over an area included between two lines running from the outer and inner angles of the orbit downward to the line of the chin. It does not reach far back on the cheek, or much under the chin. It does not reach the lower palpebral margin nor *quite* to the median line on the nose; in the lips and chin it extends *exactly* to the median line. It involves the gums on the right side up to the median line.

"At the outer, upper, and nasal border of the area the anæsthesia shades off into normal perception. On the lips and chin the anæsthesia is complete right up to the median line, and the transition to normal sensibility is sudden.

"There is no anæsthesia of the palpebral conjunctiva

Digitized by Google

of the right lower lid or the right internal canthus, or the gums of the upper jaw or the tongue.

"There is no paralysis of any facial muscle. He complained of his right eye being weak since the operation.

"I find the fundus normal and the vision good, but to the prism test I find that he has an insufficiency of the interni (probably the right) of five degrees for distant vision, twelve degrees for near vision, and he reads much better with a prism to correct that.

"Query: Did you injure, during the operation, the branch of the inferior division of the third nerve which passes under the optic nerve to the right internal rectus?"

THE PRESIDENT said there was one point worthy of special note in Dr. Bull's case, and that was the extremely satisfactory result from an operation performed externally instead of dividing the inferior dental and maxillary nerve within the mouth.

DR. MARKOE said he has had a satisfactory result in a similar case, but the operations were not performed at the same time. He operated upon a patient a number of years ago who had suffered for a long time, and severely, with neuralgia in the parts supplied by the inferior dental nerve. He trephined the canal and cut out about one inch of the nerve, and with perfect success. About three years afterward the patient came to him with neuralgia of the superior maxillary nerve, and he performed the same operation, cutting out about one inch of the nerve, going back to the point where it enters into the antrum, and destroying the nerve as far back as was possible, with the points of the scissors, and again with success, which lasted a little more than two years, when the patient returned with some slight neuralgia, affecting the region supplied by the supra-orbital nerve. The man was unwilling to undergo further operation, and disappeared from observation. Up to that time, however, covering a period of five or six years, he had experienced perfect relief.

DR. J. C. HUTCHISON presented

A SPECIMEN OF URINARY CALCULUS, WHICH WAS SPONTANEOUSLY FRACTURED IN THE BLADDER.

The specimen was removed by bilateral lithotomy from a man 23 years old, who gave the history of stone in the bladder beginning when he was 5 years old. His general health is excellent and he was always able to attend to his business without much suffering until he began to drive a cart in the city of New York, when he experienced considerable pain in the bladder after a day's drive over rough stones.

Three weeks before he applied for treatment his symptoms suddenly grew worse, and the pain was so great that he was compelled to give up work. On exploration of the bladder with a searcher, Dr. Hutchison at once detected a calculus. An instrument had never before been introduced into the bladder. Bilateral lithotomy was performed and two fragments of stone, which were shown, were removed. The patient made a satisfactory recovery. The surface of the stone shows no marks of an instrument with which it may have been broken, and the fractured surfaces are not covered with urinary deposits or smoothed by attrition, showing that the fracture was quite recent. All the evidence goes to prove that the fracture was spontaneous, that it was the result of forces acting from within, and that it occurred at the time there was a sudden increase of pain in the bladder, three weeks before the operation.

The stone is composed of calcium oxalate with a uric acid nucleus. It weighs 859 grains, is disk-shaped, measures 1½ inches in its transverse and 1 inch in its vertical diameter, and its surface is smoothly mammillated.

Dr. Ord,[1] in a paper read before the London Pathological Society, expresses the opinion that there are three methods by which a calculus may spontaneously fracture: (1) From forces arising within the calculus itself; "in an altered state of the urine the nucleus becomes swollen and acts as a bursting charge in a shell;" (2) from molecular disintegration; (3) from weakness of the layers within the crust allowing its fracture. I cannot understand how either of these methods could have caused the fracture in this specimen, nor have I any satisfactory explanation to offer.

Dr. Hutchison also presented 22 calculi removed by median lithotomy from a gentleman 66 years old, on whom he had performed litholapaxy two years before. They vary in size from a pea to a hazlenut, the surfaces are fissured, but not rough, and are of a light red color. A section was made of one for examination. It was composed mainly of uric acid with a small amount of calcium phosphate. The total weight when removed was 478 grains. The patient recovered, but died some time afterwards from causes not connected with the bladder.

He also showed the fragments removed from this patient two years before by rapid lithotrity. They weighed 225 grains, and are composed of uric acid and calcium oxalate.

DR. C. T. POORE presented two small calculi removed from a child who was operated upon in May last, by median lithotomy. The child was three and a half years of age, and he performed the second operation in September last.

THE PRESIDENT asked whether the child suffered very much after the first operation.

DR. POORE replied that the father, although perhaps his statement could not be accepted without allowance, said that the child suffered a great deal after it left the hospital where the first operation was performed. At time of discharge after the last operation, the child had no bladder symptoms.

THE PRESIDENT said he asked the question because it is well known that in the old subject two stones not infrequently exist, and escape detection. One case he recalled particularly, in which the patient was operated upon by Dr. Van Buren, and got a great deal of relief, and then pain came on again and he was lithotomized one year afterward by Dr. Buck. At the second operation, a stone as large as the original one removed by Dr. Van Buren, about the size of a walnut, was removed, and there was no evidence of facets upon its surface, nor in its interior structure after division, and the explanation of the presence of the second calculus was found in the fact that an unusually large bar between the mouths of the ureters divided the bladder into two parts.

DR. BUCK was much struck by this condition found

[1] British Medical Jonrnal, May 10, 1879, and Sept. 7, 1878.

Digitized by Google

at the time when he operated, and as the patient complained about two weeks afterward of some pain, he anæsthetized him again, and made another search, and found a small fragment of a calculus which had lodged in one of the irregularities of the prostatic portion of the urethra.

DR. POST has met with two cases in which there was contraction of the bladder between two calculi so that the stones could not come together. His cases occurred in young subjects. In each case one calculus was near the urethral orifice of the bladder and the other was far back in the cavity, and there existed a contraction of the bladder between the two which could be felt with the finger.

DR. LANGE directed attention to one way of treating

FISTULA IN ANO,

namely, cutting the entire canal out and sewing up the wound. In most cases it was a simple procedure, and he would be much obliged if the members of the Society would try it. He adopted it for the first time about two years ago in the case of a woman who had a deep-seated fistula. In that case he had a complete result, and the patient recovered in about fourteen days. He had tried it in a limited number of cases, but he had not succeeded in all. With improved technique, he thought the results would become better. So far, at least, the results were encouraging. Having a probe in the canal, he dissects all about the probe and cuts the entire fistulous canal away, including some of the tissues surrounding it, and then with catgut sutures closes the entire wound; and, besides, inserts several silkworm-gut sutures around the whole mass, as after other plastic operations, to relieve torsion and to prevent eventual separation at the wound in consequence of too early absorption of the catgut.

THE PRESIDENT said he had performed this operation four times with satisfactory results. In one instance the fistula ran from the labium to the rectum. His first knowledge of the operation was obtained from the *Proceedings of the American Gynecological Society* and from a Western surgeon who reported a number of cases.

DR. MARKOE had performed the operation twice by scraping out the fistula, but he did not get good results.

DR. GERSTER had employed this method in a limited number of cases; and, as Dr. Lange had stated, with some good results, and with some failures. He thought the method applicable in cases where the fistula is simple; where, however, there are several fistulæ crossing each other, as occasionally occurs, and running perhaps in a spiral line around a part of the circumference of the rectum, and where, after removal of all the lining of these different canals, a complicated wound remains, the results had not been very satisfactory. The relations of the wound are such, that absolute contact of all the surfaces cannot be brought about. and accumulations of secretion with retention in pockets, frustrate primary union. But certainly in simple cases, however deep, that is, up to a certain extent, the method is a rational one, and it shortens the time of cure very considerably.

NEW YORK STATE MEDICAL ASSOCIATION.

Second Annual Meeting, held in the hall of the Murray Hill Hotel, New York, Nov. 17, 18, 19, and 20, 1885.

THURSDAY, NOVEMBER 17TH.—THIRD DAY.

MORNING SESSION.

The number of members registered was 220. The total fellowship for the entire State is about 514.

THE NOMINATING COMMITTEE REPORTED THE FOLLOWING NOMINATIONS.

President.—Dr. E. M. Moore, of Rochester.

Vice-Presidents.—Drs. William Gillis, H. Van Zandt, Frederick Hyde, and Desault Guernsey.

Council.—Drs. E. M. Lyon, Ira H. Abell, Thomas Wilson, F. W. Ross, S. T. Clark, E. S. F. Arnold.

The Secretary was instructed to cast the ballot of the Association, which he did in the affirmative, and the President declared the gentlemen named elected.

DR. FELL, of Erie County, then read a paper on

SOME ETIOLOGICAL FACTORS IN THE ACNE FORM OF DISEASES.

He described some cases of rebellious acne which had come under his observation and which had finally yielded to treatment, the cure, he believed, bidding fair to be of a permanent nature. This opinion was founded on his views regarding the possible or probable etiology of the disease. It was true that his views are new, but, so far as his own observation had gone, they were substantiated by facts. In a large number of examinations of the contents of the little acne tumors he had always been enabled to find the demodex folliculorum, usually from six to ten in number; while the presence of this mite in the skin was not of unusual occurrence, and had long been known, it had not been regarded as the cause of acne form of disease. He had found them in the pus or oil globule, and not in the indurated matter. While their presence in few numbers might not give rise to apparent disease of the skin, he thought that when large numbers exist they may stand in the relation of etiological factors of considerable importance.

DR. JANEWAY, by request, made some remarks on

OXYGEN IN THE TREATMENT OF PNEUMONIA.

According to his experience, oxygen inhalation in pneumonia is of marked benefit. It is especially serviceable in commencing cyanosis or just previous to this symptom; its use should not be delayed until cyanosis has become well marked. If employed at the proper time, it will often be found to tide life over the critical point and lead the patient on to recovery.

Dr. Janeway would also add to the discussion on pneumonia, that he had seen one case of pneumonia in which the patient had a relapse at the end of a week. it being as much a case of relapse as are cases of relapse of typhoid fever. He said, further, that he had seen a number of cases in which tuberculosis of the upper lobe of the lungs had occurred in patients who had suffered from pneumonia, and he was of opinion that the attack of pneumonia had left the lung in a weakened state, fitting the soil for the development of the tubercle bacilli.

Digitized by Google

Dr. Janeway then proceded to read his

ADDRESS ON PATHOLOGY,

which was devoted largely to mention of the advances made in pathology, particularly during the past few years, and the relation of pathology to exact diagnosis and the etiology of disease. The importance of culture methods adopted by Koch, the value of the discoveries of Pasteur regarding anthrax and hydrophobia, etc., received attention. The field for labor and new discoveries is still great, and offers excellent opportunities for able and progressive young men. The backwardness of this country in new scientific discovery was attributed in large part to want of government aid, such as is given in Germany and other countries of Europe. Special paths for investigation are offered in tetanus, anæmia, malignant tumors, lithæmia, etc. Dr. Janeway thought vaccination should be done, if possible, before the third day after exposure to smallpox if it were desired to abort the attack, otherwise it may be too late.

THE LIBRARY COMMITTEE

made its report, by which it appeared that a room had been secured in the Carnegie Laboratory; the entire number of volumes was about 3450, and more than 4000 pamphlets had been received. Some interesting specimens had been presented which, it was hoped, would form the nucleus of a museum in connection with the library.

AFTERNOON SESSION.

DR. W. T. SEYMOUR reported

A CASE OF GALL-STONES, PATENT AND CONCEALED; EXPLORATORY LAPAROTOMY, WITH AUTOPSY EIGHT WEEKS LATER.

The usual symptoms were present, but the gall-bladder could not be felt through the abdominal walls. Nevertheless, the patient's sufferings were such, and her health so reduced, that an incision was made for the purpose of removing the supposed stone or stones. The gall-bladder was found empty; there was a hard nodule involving the cystic and hepatic ducts, and believing that the patient's symptoms were due to malignant disease, the abdominal wound was closed. Eight weeks later the patient died, markedly emaciated and jaundiced. In the upper margin of the right lobe of the liver was the cancerous patch; the gall-bladder was empty; the common duct impervious; the junction of the cystic and hepatic ducts was involved in the hard mass, which was of the size of a hen's egg and continuous with the right lobe of the liver. The hepatic duct was enormously dilated, and filled with gall-stones the size of a peachnut; an ulcerative opening led from the upper part of the hepatic duct into an abscess cavity, an inch and a half in diameter, in the right lobe of the liver, where a gall-stone was found. The hard mass was cancerous.

DR. ROBERT NEWMAN then read a paper on

CAUSES OF FAILURE IN THE TREATMENT OF URETHRAL STRICTURE BY ELECTROLYSIS.

He said this method of treatment had been so successful in his own hands that he was not aware of any failures until his attention had been drawn to a paper on the subject quite recently. He then made some inquiries and found that failures did sometimes occur in the hands of those of little experience with the method. The cause of failures could be given in two words—bad management. This could be classed under three heads—incompetence on the part of the operator, error in diagnosis, and faulty instruments. These headings were treated of at considerable length, the points being sustained by reference to letters, cases, and instruments.

DR. G. C. H. MEIER corroborated the statements of the author from his own experience, and testified to the excellent results obtained by this harmless method of treatment when properly carried out. It was true that it was not until he had assisted Dr. Newman in his public and private practice for some time, that he was enabled alone to give the patient the full benefit of the treatment of urethral stricture by electrolysis. The paper was also discussed by Dr. Manley.

DR. W. W. SEYMOUR the read a paper on

PELVIC HÆMATOCELE; ITS DIAGNOSIS AND TREATMENT.

A great many cases had occurred in his own and in his father's practice, going to show that pelvic hæmatocele is of much more frequent occurrence than is stated by most authorities. Speaking of treatment, he said that where there is a tendency to increase, or to interfere with the function of neighboring organs, aspiration may give prompt relief. Aspiration failing, and suppuration taking place, he was disposed to make incision per vaginum, and irrigate.

MONDAY, NOVEMBER 20TH.—FOURTH DAY.
MORNING SESSION.

DR. SAMUEL W. SMITH read a paper entitled

THE HISTORY AND TREATMENT OF THIRTY CASES OF DIPHTHERIA.

The great mortality from diphtheria was shown by figures obtained at the Board of Health for this city, from which it appeared that out of an average of about 2500 cases yearly for several years past there had been a mortality of nearly fifty per cent., the rate of mortality varying slightly from year to year. In order to test the value of a given method of treatment, Dr. Smith employed that adopted by Dr. Billington, described in a paper read before a Section of the New York Academy of Medicine. It consisted in syringing the nose and pharynx, every two hours, with a solution of chloride of sodium, a teaspoonful to a pint of warm water, and to which Dr. Smith added a teaspoonful of borax. The syringing should be done in a very thorough manner. In addition, the throat was sprayed with a solution of lime-water and carbolic acid, and tincture of chloride of iron and glycerine administered, alternated with chlorate of potash. Of the thirty cases there were five deaths.

A number of papers were read by title, and the Society then adjourned to meet in New York on the third Tuesday in November, 1886.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 19, 1885.

THE PRESIDENT, A. JACOBI, M.D., IN THE CHAIR.

A SECTION ON RHINOLOGY AND LARYNGOLOGY.

The Secretary read an application from a number of Fellows for the formation of a Section in Rhinology and

Digitized by Google

Laryngology, and, on motion, it was voted that such a section should be established.

DR. NOYES then delivered

THE ANNIVERSARY ADDRESS

before the Academy, the subject of which was "Path-finding in Medicine." In opening, he offered the hearty congratulations of the Academy, as well as his own, to their distinguished colleague, Professor Janeway, who was to have delivered the address, on his recovery from a recent very severe illness, which had prevented him from preparing it. During the past year, he said, he had had the opportunity of becoming personally familiar with much of the scientific work which was at present being done in Europe, and he had especially profited by the proceedings of the great International Medical Congress at Copengagen, and the subsequent Ophthalmological Congress at Heidelburg. From what he had observed, it was his conviction that progress was now to be made in the line of acute, deep, and accurate research. Great triumphs have been won through the agency of scientific physiological and pathological investigation, and clinical observation must now be supplemented by the laboratory. Referring to the achievements of American medical men, he said the wonder was that they accomplished so much with the meagre facilities at their command. Collective investigation is admirable in its way; but, after all, it is merely clinical knowledge, and at the present day we connot rest with clinical observation.

The microscope, he went on to say, is the great agency by which the brilliant results of modern pathology have been obtained, and though the title of his essay may at first seem somewhat grotesque, he thought it not inappropriate, when we consider how many paths through the formerly hopeless jungles of the mysteries of the human economy this instrument has assisted in opening up. Proceeding to illustrate his subject, he spoke particularly of the results accomplishad in pathological research by such men as Virchow, Fleming, and Pasteur. When speaking of microörganisms and the wonderful era in scientific medicine which the discovery of their importance had inaugurated, he mentioned that Rosenbach, in 1884, said that he knew of no less than six distinct microbes which were capable of exciting suppuration in the human body. Having spoken of the triumphs of antiseptic surgery, and the great advances which had been recently made in our knowledge of the physiology of the brain, he gave sketches of the careers of the distinguished Dr. Thomas Young, in whose time nothing was esteemed in medicine which was not of a directly practical nature; of Edward Palmer, the wonderful linguist; of Helmholtz, the inventor of the ophthalmoscope; and of Graefe and Donders, the great ophthalmologists.

Turning again to America, he spoke of the great disadvantages under which our men labor from lack of facilities. Yet a great deal has been accomplished by individual effort, and the reputation of many of our surgeons, especially those who had distinguished themselves in the field of gynecology, is worldwide. No more brilliant instance of a noble and distinguished career in the face of almost insuperable difficulties can be mentioned than that of the lamented Marion Sims.

The investigation of disease is to be prosecuted in two lines; first, the bedside study; and, second, what may be termed, the philosophical study of disease. The problem is to unite these two, so they can go hand in hand; and to-night his plea was for the laboratory. The need of the American profession is urgent; but at length the people seem to be beginning to appreciate to some extent the exigencies of the situation. Having referred to the liberal gifts of Mr. Carnegie and Mr. Vanderbilt to two of the medical colleges, which he said were most timely and hopeful, he spoke of the need of something more—such as institutions in the line of the Johns Hopkins University in Baltimore—which would be suitably equipped and offer facilities, not merely for teaching students, but for instructing teachers, and for the prosecution of the most profound original research. There is no trouble in getting our wealthy people to give liberally for the support of hospitals, dispensaries, and other charitable institutions for the sick; but they should be made to understand that their charity is not complete unless it is in part, at least, devoted to enabling the physician to treat the sick more successfully.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, November 16, 1885.

THE PRESIDENT, C. A. LEALE, M.D., IN THE CHAIR.

DR. AUSTIN FLINT read a paper on

ELEMENTS OF PROGNOSIS IN BRIGHT'S DISEASE.

He commenced by saying that at present the name Bright's disease has in the popular mind a prophetic import very similar to the judge's sentence in a case of conviction after a trial for a capital offence; being regarded as a hopelessly fatal malady. It is, in fact, worse than a condemnation to execution, for the reason that under the latter circumstances there is a possibility of a reprieve or a pardon, while in this disease there is no chance whatever of an escape from death. This prevailing impression no doubt reflects to a great extent the views of the medical profession, and accords in the main with our present pathological and clinical knowledge. But, at the same time, there are a number of circumstances which may greatly modify this very unfavorable prognosis. Thus, the progress of the disease may, perhaps, be entirely arrested. Again, the disease may be progressive, but the progress made by it be so slow that the patient may continue comparatively free from danger, though some intercurrent affection may, in consequence of the impaired condition of the kidneys, prove fatal. Still further, the chronic disease may continue indefinitely in about the same state, so, under favorable circumstances, may not prove fatal.

The prognosis in Bright's disease, Dr. Flint said, is often of great importance to a patient as regards his business and family affairs, as well as his future health. He then went on to take up a number of points which are to be borne in mind in considering this subject. Acute diffuse, tubular, or desquamative nephritis is not followed by the chronic form of the disease, and, as a rule, is characterized by no renal lesion. The same facts are also true of subacute nephritis, such as follows attacks of scarlet fever, there being no persistent renal lesion, such as is found in the chronic affection. It is to be remembered also that an acute diffuse, tubular, or desqua-

Digitized by Google

mative nephritis may be met with as an intercurrent disorder in the course of chronic Bright's disease. Under such circumstances a problem is presented which cannot at once be definitely settled, since it is not certain whether the grave symptoms noted are connected with the chronic trouble, and of the most serious import, or whether they are significant of an acute attack of nephritis which will soon subside and leave the patient in the same general condition as before. When an acute attack of this kind does occur, however, it is very apt to leave the patient with a tendency to recurrent trouble of similar character.

Passing on to the consideration of chronic Bright's disease, he referred to a number of elements of prognosis which are likely to modify it in various ways. In the first place, the disease may remain latent for a long time, and this is a most important fact. He then went on to say that in order that the prognosis may be a comparatively favorable one the kidneys must not be damaged beyond a certain point. Secondly, the important organs of the body, other than the kidneys, must be capable of satisfactorily performing their functions. Thirdly, the laws of health in general must be observed. Now, suppose these conditions to be maintained, and the patient, even if the kidneys are damaged to the extent of one-half, may continue to live in a fair state of health, these organs, under the circumstances, being able to perform their functions sufficiently well for all practical purposes. The situation may be compared to that of a patient with pulmonary emphysema, who can get along very well under ordinary circumstances, but has no reserve power in his lungs. Chronic Bright's disease may exist without discomfort to the patient for years, and then at length the pathological process in the kidneys involves the organs to such an extent that they can no longer perform their functions; or, the accessory conditions may become sufficiently changed to put the patient in jeopardy. Cardiac hypertrophy, it is to be noted, is frequently a result of this affection. But so long as the damage to the kidneys is limited in extent, and the accessory conditions are favorable, the disease will remain latent.

The object of treatment, then, is to prevent the further progress of the disease in the kidneys and to maintain favorable accessory conditions. In view of these facts, it can be readily seen how important it is to make an early diagnosis. The diagnosis made, the essential point is to see that a sufficient elimination of excrementitious products is carried on by the kidneys. Dr. Flint here remarked that practitioners, as a rule, do not properly appreciate the prime necessity of this. Thus, in consultations, in cases of kidney trouble, he had been frequently struck with the fact that the specific gravity had not been taken by the attending physician. It was very easy to find out whether this elimination was sufficient, in a manner that would answer all practical purposes, by simply ascertaining the quantity of urine passed in the twenty-four hours and testing it with the urinometer; and he thought, therefore, that inattention to the adequacy of the renal function is to be attributed to lack of appreciation of the importance of the matter.

If it is found that there is renal adequacy, the indication for diuretics, sudorifics, and hydragogue cathartics is not present. If they are not needed, their employment can only do harm, and they are, therefore, contraindicated. Dr. Flint then related the case of a gentleman, a banker, whom he saw last year. There was an increased quantity of urine, and the first time that he examined it its specific gravity was 1.003; the second time, 1.008. At the first examination the quantity of albumen was small, but at the second it was found still smaller. In neither specimen were there any casts. The average quantity of urine passed in the twenty-four hours was eighty-six ounces, and there was, therefore, no renal inadequacy. The great objects to be aimed at were the prevention of the further progress of the disease in the kidneys and the maintenance of tolerance on the part of the system. Under favorable circumstances the patient would not only continue to live indefinitely, but also enjoy a fair state of health.

He then inquired whether the diminution of excrementitious elimination is a necessary indication of danger of uræmia, and stated that it was not, because vicarious elimination might take place, and tolerance thus be established. The prognosis of uræmic coma in chronic Bright's disease is grave; but every practitioner knows that cases often recover. It may be due to intercurrent acute attacks of nephritis, or to the fact that tolerance may not be established in the system. When there is pulmonary œdema and dyspnœa there is a chance of the patient's surviving; but Dr. Flint stated that he had never yet seen a case of recovery from what is known as renal asthma, where the dyspnœa was not due to any condition of the lungs whatever, but in all probability to the effect of a poison upon the nerve-centres.

He then recapitulated his conclusions as follows:

(1) Acute Bright's disease, as a rule, does not tend to a fatal issue, or to become chronic.

(2) The same is true of subacute nephritis.

(3) Acute or subacute nephritis may occur as an intercurrent affection in the course of chronic Bright's disease.

(4) Susceptibility to the recurrence of such acute or subacute attacks is afterwards to be apprehended.

(5) Chronic Bright's disease may exist indefinitely, provided the kidneys are not damaged to the extent of more than one-half, and the accessory conditions remain favorable.

(6) The adequacy of the function of the kidneys has relation chiefly to the amount of excrementitious elimination carried on.

(7) The danger from the accumulation of excrementitious products is diminished if elimination takes place vicariously.

(8) Uræmic coma occurring in chronic Bright's disease may be due to intercurrent acute nephritis; so that if the impending danger can be averted, the patient may be restored to the same condition as previously. The same may be true of pulmonary œdema occurring in the course of Bright's disease.

(9) Renal asthma is generally, if not always, of fatal import.

DR. GEORGE L. PEABODY said that he could corroborate all the conclusions of the paper, and that he would like to emphasize, perhaps even more strongly than Professor Flint had done, the fact that chronic Bright's disease may continue indefinitely without causing serious trouble in individuals whose condition in life is such that no stress is brought to bear upon any par-

Digitized by Google

ticular organ by their mode of living. It had been his experience in quite a number of instances to find, at post-mortem examinations, an advanced stage of Bright's disease in cases where the presence of the affection had never been even suspected. In most of these it had no doubt existed for many years. He also appreciated the importance of looking at the manner in which the kidneys perform their functions. Another element of prognosis is the situation of life in which the patient finds himself. If he can surround himself with all the care that is necessary, he has a chance of living for a number of years; while those who are exposed to bad hygienic conditions and hardships of diet, will be likely to succumb in a comparatively short space of time.

DR. EDWARD G. JANEWAY remarked that the few words which he had to say would be much in the same strain as those of Dr. Peabody. For individuals in the poorer conditions of life, the prognosis of Bright's disease is of the gloomiest kind; but if the patient is so situated that he is able to go to warm climates in winter and take every possible care of himself, he can probably live for a number of years in comfort. He mentioned a case in illustration, of a gentleman who for a time lost flesh rapidly and seemed to be in a bad way generally, but who, by travel and proper care, had been improving very markedly, and had even gained sixty pounds in weight. Thus, again, in the prognosis of Bright's disease, there is an intermittent element to be taken into consideration. For considerable periods at a time albumen and casts may be entirely absent from the urine, and then return again. In this connection he mentioned the case of a lady who at one time had dropsy from Bright's disease, but who is now in a fair state of health and seems likely to remain so. But in both the cases mentioned, Dr. Janeway said, the most careful attention is paid to every circumstance of the patient's condition, and any slight disturbance of the health is at once corrected, if possible. In the first instance the disease has already lasted eleven years, and in the second, five years. He had also one gentleman under observation who was told seventeen years ago that he had incurable Bright's disease. Personally, he had first seen him five years ago, when he had a second attack. The prospect then looked gloomy, but the patient has now to a great extent recovered from this second attack. While too dark a view may be taken of cases of Bright's disease, we must not forget that, on the other hand, too favorable a prognosis may be given. If no albumen or casts are found at the time of examination, it is very desirable that the examination should be repeated. Like Dr. Flint, he thought the quantity and specific gravity of the urine of the greatest importance. Rigidity of the arteries and hypertrophy of the left ventricle of the heart, constitute grave elements in the prognosis.

DR. ISIDOR P. OBERNDORFER spoke of the etiology as possibly modifying the prognosis. Schumacher had called attention to the fact that casts and albumen are sometimes found in the urine in connection with secondary syphilis in cases which had not undergone mercurial treatment, and that when the syphilitic trouble abated the kidneys recovered their normal condition. He had not personally met with an instance of this, but he thought it well that this possible source of origin should be borne in mind, as it would greatly influence the prognosis.

DR. E. M. MOORE, of Rochester, said that he wished to express his gratification in recognizing the progress which has been made in our knowledge of this disease. He would like to ask Dr. Flint one question, the consideration of which had been left out. He had stated that there were many cases of albuminuria, especially those of an acute or subacute character, which existed for some time without any tendency to become chronic; such cases as occurred in connection with scarlet fever or diphtheria, or arose from causes which were not thoroughly understood. What he wanted to know was, how long a time Dr. Flint had known albuminuria to exist as a constant condition, and yet not to assume a chronic form.

DR. FLINT replied that the time was very variable. It was well known that often acute nephritis from scarlet fever ended in recovery. The trouble might last two or three weeks, or four or five months; there was no definite duration.

DR. MOORE went on to say, that it would hardly be reasonable to suppose that such cases could last for a year; but it was his own belief that we have cases of albuminuria which go on for months, which do not get well and finally terminate in loss of life, and yet which at the end of a year have not changed the condition of the kidneys. There would be a great many such cases if they were left uninterfered with. He then related a case which he had under his care during the late war. A young soldier had had albuminuria for several months before he was seen by Dr. Moore, and it lasted a year longer. He took medicine every day during this period, and at the end of twelve months the symptom disappeared. Since then the patient has never had any trouble; but he believed that if he had not been treated, the original trouble would have progressed, and a fatal termination would have been reached. Instead of that, the patient is living and perfectly well to-day. His object in relating the case, he said, was to impress upon his hearers the great length of time which the state of affairs to which he had referred, might exist. In such instances the exact diagnosis is not easy; but he was glad to say that Sir Wm. Gull, whom he had seen during the past summer in London, had entirely agreed with him as to the occurrence of the kind of cases mentioned.

DR. E. S. F. ARNOLD said, in reference to the duration of albuminuria, that he remembered a case, which was also one seen during the late war, in which he gave a certificate of disability to a gentleman who was drafted, because he had had albuminuria for twelve months. This condition lasted altogether for eighteen months, when it entirely disappeared. The patient has had no return of it since, and to-day is apparently in perfect health.

DR. PEABODY said he would like to inquire whether, in these long-continued cases of albuminuria, casts are also found in the urine at the time the albumen is present.

DR. C. S. WOOD said it is a very important question as to whether cases of chronic Bright's disease ever recover. He is one of those who agree with Dr. Moore that cases occur in which albumen and casts are found for a long period in the urine, and then disappear;

Digitized by Google

after which the patient goes on to live for years. He then related the case of a gentleman, sixty years of age, a captain in the United States marine corps, who is accustomed to living well. Five years ago, he was pronounced to have Bright's disease by physicians in Chicago; after which time he had casts and albumen in his urine, more or less constantly, until two years ago, when he came under Dr. Wood's observation. At that time the specific gravity of the urine ranged from 1000 to 1.004, and he was much reduced in flesh. After treatment for a year, however, he had gained over forty pounds, and he is now as well as ever. The albumen and casts have disappeared, the specific gravity of the urine is from 1.010 to 1.020, and he has every appearance of perfect health. Dr. Wood said that he ought to add, that in early life the patient had been addicted to the use of intoxicating drinks, but that since he had been troubled with albuminuria he had given them up. The important point is, whether these cases past middle life ever recover. Personally, he believed that this was the case more often than was generally supposed. and that more caution should be employed in giving unfavorable prognosis before the patient's friends.

DR. F. V. WHITE made an inquiry in regard to the renal asthma mentioned in the paper, and Dr. Flint replied that this is a form of dyspnœa which is entirely independent of any trouble in the lungs; being in all probability a cerebral condition, and due to the action of the poison of certain retained excrementitious products upon the nerve-centres. Dr. Flint went on to say that he had met with cases somewhat similar to those mentioned by Drs. Moore and Wood, and the explanation of them, he thought, was this: In the cirrhotic or contracted kidney, it is not uncommon for all the symptoms to disappear for a time; and they may disappear altogether. The kidneys have received a certain amount of damage, but if this does not exceed half of their extent they can perform their functions sufficiently well under favorable conditions. Recovery may then take place in a certain sense; but the kidneys will always remain impaired, just as the lungs do after recovery in tuberculosis.

DR. T. R. VARICK, of Jersey City, said that in the prognosis it is of service to consider whether the trouble is simple and uncomplicated, or secondary to cardiac disease, poisoning by lead or other toxic agent, the excessive use of alcohol, or to some other pathological factor. Then the natural tendency and the selection of termination of Bright's disease must be taken into consideration. Some cases end in apoplectic coma, some in pulmonary œdema, and others in heart-failure, All these various circumstances have an important bearing on the prognosis. In many instances albuminuria is merely a symptom of other conditions besides disease of the kidney, as, for instance, the presence of a gravid uterus. It must not be forgotten that it is not a disease itself. The intermittent character of albuminuria is often obscured. Dr. Varick related a case in which the patient suffered from asthma for a year; but there had never before been any suspicion of kidney trouble. Previously he had had an attack of acute rheumatism. which left him with mitral insufficiency. The quantity of urine passed in the twenty-four hours was down to four ounces, and it was found that it was more than one-half albumen. There were pulmonary œdema and anasarca of the lower extremities. Yet, notwithstanding this discouraging state of affairs, the patient improved under treatment, and is now very much better in every way. It was last spring when the condition was so serious. At times there is a complete absence of albumen from the urine, and then again it will recur, the reason for which Dr. Varick supposed to be in the continuance of the cardiac trouble.

DR. HENRY F. QUACKENBOS said that ten years ago a patient of his contracted disease of the kidneys. In six weeks after the discovery of the trouble the condition became so alarming that he called in Professor Flint in consultation. The patient was confined to bed with the most extensive œdema, and looked like a piece of wax. Dr. Flint saw him four times, and expressed his approval of the treatment which had been adopted. The trouble gradually subsided, the albumen disappearing from the urine within four weeks, and to-day the patient is entirely well. Dr. Quackenbos also related another somewhat similar case.

DR. JANEWAY mentioned a case in which there was Cheyne-Stokes respiration, which is usually regarded as of fatal import. Yet the patient had no less than four attacks; dying in the last. He had had Bright's asthma five years before. He doubted whether this phenomenon is simply of nervous character; and thought that it is, in some manner at least, due to the effect of a poison on the red corpuscles of the blood which acts somewhat in the manner of carbonic oxide.

Dr. Janeway then exhibited some

PATHOLOGICAL SPECIMENS

taken from the body of a woman who was admitted to the hospital under the supposition that she was suffering from puerperal mania. She had been confined three weeks before admission, and fourteen hours after the birth of her child fever had set in, which continued up to the time of her death. It was learned that she had had an attack of malarial fever two months before confinement. The autopsy revealed the characteristic lesions of typhoid fever in the intestines, and also marked pigmentation of the liver and spleen from the recent malarial trouble. During her stay in the hospital the patient exhibited great irregularities in temperature, and she died on the twenty-first day from the commencement of the attack.

It might have been supposed that this was a case of typho-malarial fever; but, from the light thrown on it by the history and the autopsy, there could be little doubt that it was one of true typhoid. The history showed that the malarial poisoning, of which the marked pigmentation of the liver and spleen afforded plain evidence, had occurred two months before the beginning of the typhoid fever. In connection with the latter there were some bronchitis and broncho-pneumonia, as shown by the post-mortem. The six or seven patches in the small intestine were ulcerated out, and a few typhoid bacilli were also found in the intestinal tract. Dr. Janeway had met with two other cases (in one of which an autopsy was made, and in the other not) in which there was typhoid fever, rather than puerperal sepsis, following confinement. The pigmented spleen, which was of a dark chocolate hue, and also greatly enlarged, and the small intestine, showing the typhoid lesions, were exhibited.

CORRESPONDENCE.

ŒDEMA OF THE LUNGS.

To the Editor of THE MEDICAL NEWS.

SIR: Your editorial, on œdema of the lungs, in THE MEDICAL NEWS of October 31, in which you review the status of the discussion on the mode of production of non-inflammatory œdema, induces me to communicate to you the following notes of a case that but lately terminated fatally in my hands, which, I think, illustrates the correctness of Welch's theory:

A woman, aged 61, good family history, a well-to-do farmer's wife, of spare build, chest not barrel-shaped, had been suffering for thirty-seven years from chronic bronchial catarrh. Mitral and aortic insufficiency were recognized by me when first seen more than ten years ago. While I have been her medical adviser she has been frequently treated for acute exacerbations of the bronchial catarrh, for pulmonary congestion, at times amounting to inflammation, and for hepatic torpor, which latter would be especially troublesome in summer and fall. During the past three years she has been remarkably healthy and had little trouble with cough. One year ago she came to me with considerable œdema pedum. This was promptly relieved by Guy's pills.

On August 26th last she presented herself at my office with feet slightly swelled, and complaining that her stomach felt swelled, especially after meals. The pulse was 100–110; the respiration was slightly increased, 24–28. September 18, there was increased cough, numerous dry râles over both lungs; pulse 100, regular, weak; no increase in the dropsy. She comes to office, a distance of three miles, and spends several hours in town.

September 27.—Found patient in bed; great cyanosis; face and hands steel-gray; veins greatly distended; jugulars pulsating heavily; sensorium dulled; no dyspnœa, but rapid and extremely shallow respiration, 48; strong cough; raw, small, soft râles exceedingly numerous over both lungs; no pericarditis; no pleuritis; no pneumonia; slight œdema pedum; abdomen 31¼ in.; her normal girth being about 28 in.; urine somewhat diminished in quantity and high colored, contains a trace of albumen; face puffy; the cardiac dulness is increased; the heart's action is peculiar; the pulse is hard, throbbing, regular, equals 48; the heart beats are heavy, thumping, regular, equal 48; the first mitral sound is clear, the second reduplicated; no murmur; the reduplication is heard over all four valves, but especially clearly over the mitral, aortic, and pulmonary. After four or five minutes, without any cause from the patient, and without any warning, the pulse becomes low, hard, 96, but remains equal and regular. The heart's impulse is still strong, its action is regular, equals 96. Now there is no trace of reduplication, but a very marked mitral and aortic regurgitant murmur. Again, after a few minutes, just as suddenly as before, the pulse falls to 48. When the pulse is 48 I imagine that I can make out just a shadow of a beat between each of the heavy throbs; no trace of a corresponding heart-beat can be made out. Here the beat is 48, and the beat of the sounds is reduplicated.

October 3.—More obtunded sensorium; speech slow; recollection bad; forgets what she wants to say; hearing less acute; swallowing difficult, clearly owing to tardy nerve action. Respiration as before; heart and pulse as before, only made fuller; increase in cough and in number of râles; lungs are clearly becoming filled up rapidly; very slight increase in ascitis; no pericardiac or pleuritic effusion; no pulmonary solidification; at rare intervals she bring up a little, thin, mucoid sputa. The respiration is regular, easy, only extremely shallow. There is not now, nor ever has been, any increase in temperature.

4th.—Pulse stronger to-day, but otherwise remains unchanged; is taking digitalis and arsenic; increased œdema pulmonum; increased cyanosis; increased cerebral obtuseness. The patient's vital fire is being slowly but surely smothered.

5th.—Under digitalis and carbonate of ammonium the pulse has become 80–88; has lost the changing from a slow to a fast pulse; some of the pulse and heart beats are, however, irregular as to time, rhythm, and celerity. Œdema pulmonum seems somewhat improved; respirations being 40, regular, easy; but there have been several mild dyspnœic attacks. Mental dulness, bordering on stupor; cyanosis increased, face and hands deep gray-blue; veins of face, neck, hands, and chest stand out in heavy cords; heaving pulsation in the jugulars. Death occurred October 6, at 11 P. M.

Death in this case was clearly due to pulmonary œdema. There was to the last but a moderate effusion into the peritoneal cavity, and none at all into the pericardial and pleural sacs. There was no recognizable pulmonary hepatization; *there was no new bronchial catarrh; on the contrary, from the first an absence of any but the mildest symptoms common to chronic bronchitis.* The albumen amounted to but a trace, and the urinary secretion, though less than normal, was not greatly diminished. The rapidity with which the end came on, only six weeks after the first signs of œdema pedum were observed, and the manner of death, counterfeiting that of death in pneumonia when œdema pulmonum supervenes, distinctly point to the same cause. This œdema, I think, cannot but have originated in a weakened left heart.

Trusting that this report may be of some interest, I remain very respectfully yours,

O. T. SCHULTZ.

November 3, 1885.

A CASE OF FRACTURE OF THE CORACOID.

IN THE MEDICAL NEWS for November 21, 1885, appeared an interesting article by Dr. Johnson, of Baltimore, upon fracture of the coracoid process. I am very certain that I have had a case of this kind, but have hesitated to report it, although notes were taken at the time for that purpose.

I was called November 5, 1881, to see Mr. J. McC., a stout farmer, aged about fifty-six. It was butchering day; and while his clothes were wet with blood, and he was somewhat under the influence of liquor, he went into a stall to feed a colt. The colt became frightened, threw him down, and struck him many times with his forefeet as he lay. I found him badly brused. Examination showed no dislocation or fracture except that, by chance, crepitus was noticed at a point in front of the right shoulder. The head of the humerus was in

Digitized by Google

place, and every motion could be made passively. The spine of the scapula and the clavicle were traced, as carefully as possible, and appeared uninjured. The crepitus and point of special tenderness were very strictly localized at a point internal to the shoulder-joint and below the clavicle. I could think of nothing there to crepitate except the coracoid, and diagnosed its fracture. It was dressed like a broken clavicle, omitting the axillary pad.

Upon looking up this form of fracture in Erichsen's *Surgery* I could find no distinctive symptoms of it—and the statement was made that only ten or twelve cases were on record. So, the next day, I requested Dr. J. C. Nelson, an experienced surgeon, to see the case with me, and we made a careful examination of the joint. The conclusion was that the crepitus, distinct, though difficult to obtain, the localized tenderness, the peculiar situation of the injury, and the absence of any other symptom allowed of no other diagnosis. The patient made a very good recovery.

I see no reason why the coracoid should not be broken by direct violence when subjected to it. The accident may easily escape notice, which would make little difference in treatment. But if some pointed object should strike forcibly the point below the clavicle and just internal to the head of the humerus, there would seem to be no reason why fracture of the coracoid should not be produced.

F. W. HIGGINS.

CHEMUNG, N. Y.

NEWS ITEMS.

WASHINGTON.

(*From our Special Correspondent.*)

SANITARY CONDITION OF FOREIGN PORTS. — The United States Consul at Gibraltar, under date of October 9, 1885, reports to the Department of State that he regrets to have to report that, after the lapse of twelve clear days, three fresh cases of cholera have occurred at that port within the past forty-eight hours, and that the first case has already proved fatal at the date of his dispatch.

He says that the authorities of Gibraltar, treating the cases as sporadic, have continued, since the 30th ultimo, to issue clean bills of health to vessels clearing from the port departments, but that it does not alter the course of proceedings on the part of the Consulate, which still continues issuing foul bills of health, or endorsements to the same effect, to clearances for ports in the United States, and will continue to do so, as long as any case of cholera prevails there, or at the neighboring Spanish lines, where the malady seems to be decreasing.

The United States Consul at Catania, Italy, reports, under date of October 17, the sanitary condition of that port for the month of September, 1885. He says he is unable to make weekly reports, as the statistics of the Board of Health are prepared monthly, and not for each week, and he is unable to get their report until the middle of the month following. The prevailing diseases are diarrhœa and dysentery during the summer months. The report for September shows an improved condition of the health of the city. His report for August showed the number of deaths to be 383, while in September there were 282, from the following causes:

Smallpox, 1; typhoid fever, 22; dysentery, 37; apoplexy, 9; eclampsia 9; bronchial affections, 10; pneumonia, 8; tubercular consumption, 11; heart disease, 5; diseases of indigestion, 22; diseases of the liver, 8; diarrhœa, 100; suicide, 1; homicide, 1; other diseases, 38; total, 282. The total of deaths gives a ratio of $2\frac{88}{100}$ to each 1000 inhabitants. The case of smallpox was that of a Greek sailor, who died aboard ship in the harbor. There had been no case of cholera or other contagious disease except the one mentioned. He says that the people, who are generally ignorant and superstitious, were greatly alarmed on account of the cholera in Palermo. Those who were able fled to the slopes of Ætna. Riots were apprehended, but an additional force of troops sent by the Government maintained order. The sanitary condition of the city had somewhat improved since his last report. Disinfectants were scattered in various streets. The main streets were kept very clean, but the side streets and alleys were still in filthy condition. The drainage is very poor, and is confined principally to the main streets. The homes of the poorer classes are densely crowded. In case of an epidemic there, such as cholera, the mortality of the city would be very great.

CHICAGO.

(*From Our Special Correspondent.*)

CHARLES GILMAN SMITH, M.D. (Medical Department, University of Pennsylvania, 1851), has been elected orator for 1886, by the Alumni Association of the Medical Department, University of Pennsylvania.

COUNTY PROVISION FOR THE INSANE.—At a meeting of the Chicago Medical Society, held October 19, 1885, a committee was appointed to investigate the condition of the Cook County Insane Asylum. On Saturday evening, October 24th, a meeting of citizens was called to discuss the present condition and alleged mismanagement of the same institution. These two committees have conferred together, and determined upon a definite line of investigation. A great mass of evidence has been secured, and a radical change in the management of the Asylum is anticipated.

During the past two years the 1163 Cook County Insane Asylum patients cost $358,039.

CHICAGO GYNECOLOGICAL SOCIETY.—At the annual meeting of the Chicago Gynecological Society, held October 16, 1885, the following officers were elected for the year 1885-86:

President.—Dr. Daniel T[illegible]son.

Vice-Presidents.—Drs. Henry T. Byford, and Charles Warrington Earle.

Secretary and Treasurer.—Dr. Edward Warren Sawyer.

Editor.—Dr. W. W. Jaggard.

STUDENTS WITH THE MEDICAL COLLEGES.—The total number of matriculates at Rush is 406; at the Chicago Medical College, 120; and at the College of Physicians and Surgeons, 160.

COLLEGE OF PHYSICIANS AND SURGEONS.—The following changes have been made in the Faculty:

Mr. C. B. Gibson has been appointed to the Chair of Inorganic Chemistry; Dr. C. A. Kelsey to the Chair of General Pathology and Pathological Anatomy; Dr. F.

Digitized by Google

B. Earle, Curator of the Museum; Dr. B. W. Rogers, Assistant Demonstrator of Anatomy.

CHICAGO POLYCLINIC.—On Thursday evening, November 20th, a number of physicians met in the Club-room of the Palmer House and formed the "Chicago Polyclinic Society." The following officers were elected:

President.—Dr. Charles T. Parkes.

Vice-President.—Dr. W. F. Coleman.

Secretary.—Dr. E. C. Dudley.

The prominent physicians of the city and region are interested in the movement. The plan is to establish a polyclinic similar to the institutions in Vienna and Berlin.

COOK COUNTY HOSPITAL.—The County Hospital is a magnificent edifice, constructed in accordance with recent principles of hospital architecture. There are 550 beds. The material, especially in the wards for acute surgery, is large, varied, and valuable for class instruction. Internes are chosen by competitive examination, and nurses are supplied by the Chicago Training School, one of the most efficient institutions of its kind in the country. The members of the visiting staff are elected by the Hospital Committee of the County Commissioners. Abuses in the management of the institution have existed for a long period of time. It is difficult to understand how the duties of the executive officers can be faithfully performed, in view of the fact that the institution is an infamous political machine. The citizens of Chicago are being roused from their apathy, and a revolution is anticipated, which may rival the change in Blockley under the influence of the Committee of One Hundred. During the past year 329 pregnant women have been received into the hospital; 258 births have occurred, with only one maternal death. The freedom from puerperal disease is due exclusively to the zeal and intelligence of the internes, who have taken a special interest in this department.

MONTREAL.

(From our Special Correspondent.)

THE SMALLPOX EPIDEMIC.—Smallpox is rapidly diminishing, principally because it is burning itself out, and partly, owing to the vigorous efforts of the Board of Health, during the last month, in enforcing either removal to hospital or isolation. A special court has been instituted for the rapid trial of smallpox cases, and there are daily convictions of persons who decline hospital accommodation or isolation. Several physicians have been lately fined for failing to report cases of smallpox under their care, although the daily death-rate in the city and its suburbs has fallen from 50–60 to 10–15; yet the disease is rapidly spreading through the country districts, and in many of the small towns and villages has reached alarming proportions. Montepello and other places refuse to enforce vaccination and isolation, but in most of the country municipalities boards of health, more or less efficient, are established, and vaccination is being enforced. The opposition to vaccination outside the great cities is not very violent, though many of the country doctors having been educated by antivaccinationists are not ardent disciples of Jenner; still, being unsupported, they are falling into line.

The public demonstrations held in various parts of the country, condemning the Government for the execution of the rebel, Louis Riel, will, it is thought, have at least one effect, viz., the spread of the French Canadian national disease, *picotte*.

ANOTHER RESIGNATION FROM THE INTERNATIONAL CONGRESS.—It has nowhere been mentioned in the medical press that another of the Vice-Presidents of the Congress has resigned, yet it is over a month since Dr. R. Palmer Howard, Dean of the McGill Medical Faculty, sent in his letter of resignation. Dr. Howard was written to and asked to say whether he accepted or declined his appointment as Vice-President, and he felt bound to decline, not being in sympathy with the action of the present Committee. The Canadian members have been placed in an awkward position in regard to the Congress, being to a certain extent foreigners, and being asked to join the organization merely out of courtesy, they did not feel disposed to join in the family quarrel. They, although altogether disapproving of the ousting of the old Committee, thought it better to do nothing, though most of them, if they were asked to reply to the circular advising them of their reappointment, would decline to have anything to do with the Congress as at present constituted.

ANNUAL REPORT OF THE SURGEON-GENERAL OF THE ARMY.—The Surgeon-General, in his annual report, states that the general health of the Army has been good; the rate of admission to sick report being decidedly lower than that for the previous year and preceding decade, while the death-rate from all causes shows an equally marked reduction.

Admissions for disease were less frequent, the rate being fully one-fifth lower than for the previous year.

Among the interesting additions to the Museum during the year may be mentioned, a model of the course of the fibres in the human brain, made under direction of Professor Aeby by F. Buechi, of Berne, Switzerland; a set of anthropometric apparatus and instruments similar to that shown in the Health Exhibition in London, in 1884, and devised by Mr. Francis Galton; a series of colored plaster casts of frozen sections of the human body, as made by Professors Braune, His, and Rauber, of Leipsic; and a series of microscopes illustrating the history of the origin and development of this instrument.

During the year there were added to the Library 6481 volumes and 9420 pamphlets. Of these, 456 volumes and 5706 pamphlets were obtained by presentation or exchange, the remainder being obtained by purchase.

Among the additions were 989 volumes of journals and 211 volumes of transactions. Of the pamphlets, 1941 were medical theses. There are now in the Library:

Volumes of medical journals	23,039
" " " transactions	3,440
" " bound theses	1,385
" " " pamphlets	1,213
" " other medical books	43,142
Total volumes	72,219

Digitized by Google

Medical theses, unbound	40,524
Other medical pamphlets	55,399
Total theses and pamphlets . .	93,923

All new medical publications are now promptly received by the Library, and its use by physicians in all parts of the country is steadily increasing.

Volume VI. of the *Index-Catalogue*, including from "Heastie" to "Insfeldt," forming a volume of 1051 pages, has been printed and the edition distributed. The preparation of the manuscript of Volume VII. is well advanced, and the first part of it is now going to press.

The manuscript of the third medical volume of *The Medical and Surgical History of the War*, and the last of the series, is now well advanced toward completion; its earlier chapters are in the hands of the printer. The work will probably be ready for issue during the coming winter.

The plans for the fireproof building for Medical Records and for the Army Medical Museum and Library have been approved by the Commission, and after due advertisement the contract for constructing the building has been awarded to Messrs. Bright & Humphrey, of Washington, D. C.

The original estimate of the cost of the construction of this building was $250,000, and as only $200,000 were appropriated, some changes in the original plan were necessary. These changes make the building a very plain and simple one, and somewhat reduce its size from that originally proposed; but it is believed they have not in any way impaired its security, and that it will afford space sufficient for all absolute necessities for some years to come.

Estimates have been forwarded for the necessary shelving, cases, etc., to fit up the building for its purpose; and it is hoped that it may be completed, and the invaluable collections for which it is destined to provide removed from their present dangerous situation, and safely stored in it by the spring of 1887.

SANITARY INSPECTION DISCONTINUED.—Owing to the decrease of cholera, instructions have been given to discontinue the services of most of the sanitary inspectors of the Marine-Hospital Service attached to the United States Consulates in Europe. The inspectors at Mediterranean and Cuban ports will be retained for the present.

PRIVILEGED COMMUNICATIONS.—A physician was fined at Oswego, last week, $250, with the alternative of six months' imprisonment, for contempt of court in refusing to testify in a criminal case. He pleaded, unwillingly, as a defence that his testimony would involve the disclosure of professional secrets.

THE HEALTH OF CANNES.—In the presence of the numerous demands for information which are addressed to them respecting the sanitary state of Cannes, the different foreign consuls resident there have felt that they ought, in order to be of service to their countrymen, have recourse to publicity to let them know that Cannes has, during the summer of 1885, been entirely free from cholera, that the medical men have not certified to a single case of this malady. The general state of the public health is, and has not ceased to be, excellent. Travellers to Cannes, by Paris, Lyons, and Marseilles, are not subjected to any kind of disinfection, on any point of their journey.

OPHTHALMOLOGY IN VIENNA.—DR. ERNEST FUCHS, the newly appointed professor of ophthalmic surgery in Vienna, in his opening lecture, gave an interesting account of the history of ophthalmological teaching in that university. In the last century, the surgery of eye diseases was practically resigned by the members of the regular profession into the hands of charlatans. In the university there was no chair assigned to the subject and the only instruction which was given was contained in a few lectures delivered by the professors of surgery and anatomy. This state of things had lasted a long time, when one of the Empress Maria Theresa's court ladies, the Countess Taroucca, became blind. The medical men consulted were unable to agree as to the nature or treatment of the affection, some diagnosing cataract, and advising an operation, whilst others pronounced it to be amaurosis, and incurable. In order to solve the difficulty, Dr. Wenzel was summoned from Paris. He recognized the affection as cataract of an unusually dark color, and operated successfully. As Dr. Wenzel's journey was a very costly affair, an arrangement was made to utilize it as far as possible; and so, during the time he remained in Vienna, he instructed three young medical men in eye diseases. The most prominent of these was Barth, then professor of anatomy and physiology, who was afterwards appointed to carry on the instruction in ophthalmology. He chose as his assistant Joseph Beer. It was not long before Beer surpassed his master, ultimately becoming the most renowned ophthalmologist of his time. He was, however, not fully installed as professor until 1818, when the first chair of ophthalmology was created, at which time he was 55 years of age. One of Beer's assistants was Friedrich Jäger, from Germany. He won his master's esteem, and married his daughter. He was not only a brilliant operator, but a cultured man of the world, and was Prince Metternich's private physician. His son, Edward Jäger, the lecturer's immediate predecessor, is universally known in connection with ophthalmoscopy. —*British Medical Journal*, November 21, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING NOVEMBER 28, 1885.

MARMION, R. A., *Surgeon*.—Detached from Marine Barracks, Washington, D.C., December 7, and wait orders.

MOORE, A. M., *Surgeon*.—Ordered to Marine Barracks, Washington, D.C., December 7, 1885.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM NOVEMBER 24 TO NOVEMBER 30, 1885.

WINNE, C. K., *Captain and Assistant Surgeon*.—Assigned to duty as Post Surgeon Benicia Barracks, and Attending Surgeon at Benicia Arsenal, California.—*S. O. 119, Department of California*, November 20, 1885.

TAYLOR, ARTHUR W., *Captain and Assistant Surgeon*.—Granted leave of absence for one month, to take effect December 5, 1885.—*S. O. 116, Department of the Platte*, November 20, 1885

ORIGINAL LECTURES.

ON THE TREATMENT OF PAINFUL MENSTRUATION AND STERILITY FROM FLEXION.

A Clinical Lecture, delivered at the Hospital of the University of Pennsylvania.

BY WILLIAM GOODELL, M.D.,
PROFESSOR OF GYNECOLOGY IN THE UNIVERSITY OF PENNSYLVANIA.

GENTLEMEN: While our patient is getting her ether in the waiting-room, let me give you her history. It is a history which will soon be to you as familiar as household words, whether you practise in cities or at cross-roads. She is a young woman who has been married eight years; but she has never conceived, and since puberty has suffered from very painful menstruation. Since her marriage, her periods, as is usual in such cases, have been getting more and more painful. At present, not only are they unbearable, needing large doses of opium, but she is yearning to become a mother.

Now, what lesions shall we probably discover in this case? Ten to one, a womb bent forward on itself, and a narrow uterine canal. True, the displacement may turn out to be a retroflexion, but this is a lesion almost peculiar to the childbearing womb, while anteflexion is the natural condition of the nulliparous womb. Here, let me disabuse your minds of a prevalent error, viz., that anteflexion in itself is a pathological condition. Many text-books speak of this flexion as a lesion, and exhibit many forms of pessaries devised to rectify this so-called displacement. But in the great majority of cases neither anteflexion, nor, for the matter of that, anteversion, is pathological. In almost every unmarried or barren woman you will find the womb either bent forward or tilted forward, and resting on the bladder; for this in varying degrees is its natural position. The mistake made, is in attributing to this natural position of the womb the various forms of pelvic trouble, especially that of irritability of the bladder, to which women are so liable. But the kinship between the brain and bladder is a remarkably close one. This has lately been studied by two Italian physiologists, Mosso and Pellacani, who go so far as to contend that "every mental act in man is accompanied by a contraction of the bladder." The irritability of the bladder is then one of the first symptoms of loss of nerve control. Everybody is liable to it. You, on examination day, will be annoyed by it. Many a lawyer before pleading an important case, and many a clergyman just before delivering a discourse, is compelled from sheer nervousness to empty the bladder. So it is with the lower animals, which, when frightened, micturate involuntarily. A nervous bladder is then one of the earliest phenomena of nervousness. Now, a hysterical girl, or a woman whose nervous system has collapsed under the strain of domestic cares, consults a physician for such symptoms of nerve prostration as wakefulness, utter weariness, a bearing down feeling, backache, and perhaps, above all, an irritable bladder. Upon making a digital examination, he, of course, finds the fundus of the womb resting on the bladder, and at once jumps to the conclusion that the whole trouble is due to the pressure of the womb on the bladder, viz., to the existing anteflexion or to the anteversion, as the case may be. He now makes local applications and racks his brain to adapt or to devise some pessary capable of overcoming the supposed difficulty, forgetting that the upward, or shoring, pressure of the pessary on the bladder must be greater than the corresponding downward, or gravity, pressure of the womb. There is, in fact, no pessary but the dangerous stem-pessary which can meet the end without pressing upon a fold, or double thickness, of the bladder. But, very fortunately, anteflexion is not often pathological. It is certainly not pathological in the foregoing instances; for the symptoms, especially the vesical ones, are not due to the pressure of the womb upon the bladder, but to sheer nervousness, or nerve prostration, which is the thing to be treated, and not the womb. There are exceptions to this rule, but not many; for instance, a womb, heavy from subinvolution or from the presence of a fibroid, may make uncomfortable pressure on the bladder.

If anteflexion is the natural position and condition of the womb, when is it pathological? It is pathological whenever it is the cause of dysmenorrhœa or of sterility. Usually dysmenorrhœa and sterility are associated, but occasionally the latter is the only symptom; for it is evident that the crooked womb can more readily expel fluid contained within it, than admit a fluid outside of it. The phenomena of a typical case of dysmenorrhœa from anteflexion or from retroflexion, are as follows: At the outset of menstruation, the first few drops are somewhat painful. The pain then increases in severity until, reaching its acme, a slight gush of menstrual fluid takes place, followed by a lull in the sufferings. The pain then gradually increases until it culminates in another gush. The meaning of this is, that the bend in the womb imprisons the menstrual fluid, which goes on collecting in the cavity until the swelling up of the womb straightens out the bent portion, dilates the narrow canal, and allows the pent-up contents to escape, just as the coils of a hose first swell and then straighten out before the water can flow through them. Relief from pain lasts until the fluid begins again to collect. This is called stenosis from angulation.

Sometimes a girl has little or no pain at her menstrual periods. She marries, does not conceive, and by and by dysmenorrhœa sets in, which goes on increasing. What is the explanation of this? It means that the flexed canal of the womb was originally just large enough to permit the slow escape of the menstrual fluid; but that the congestions from sexual intercourse have caused a thickening of the lining membrane of this canal, which has narrowed its calibre. Then again, the uterine efforts to force out the pent-up fluid cause the various tissues

Digitized by Google

of the womb to hypertrophy. We see this also in unmarried women, the dysmenorrhœa increasing with their age. Nature intends that the periodical congestions of the womb should be interrupted by pregnancy and lactation, and without these interruptions the mucous lining of the womb is liable to thicken, and by its thickness to narrow the canal. If then to these menstrual congestions be added the sexual congestions of marriage, this hypertrophy is greatly increased, and the barren wife suffers more than the old maid.

But here comes our patient. Let me examine her. Sure enough, she has an anteflexion, for through the anterior wall of the vagina I feel the body of the womb resting upon the bladder. The cervix is long and conical; the os externum very small.

I pass the sound. It stops, as you see, at the internal os,—viz., at the beginning of the bend,—and I cannot coax it in any further. By introducing the speculum, and straightening the womb by traction made with a tenaculum, the sound now goes in, but even yet with difficulty. It gives a measurement of nearly three and a half inches, which is a large measurement for a young woman who has not borne any children. This hypertrophy is owing partly to such repeated congestions as I have just described, and partly to the muscular effort made by the womb to extrude not only the menstrual fluid but its mucous secretions.

Now, what is the remedy for this condition? For a number of years the operation most in vogue was the cutting, or bloody operation of Sims. By it the canal is enlarged by incisions. But the objections to this plan are: that it is a dangerous operation, having caused the death of many patients through peritonitis; that it is not a very successful operation, as the incisions are liable to heal up and the dysmenorrhœa to return; and, finally, that it always deforms the cervix, and sometimes causes lesions analogous to those resulting from a natural laceration during labor. I shall not, therefore, burden you with the details of this operation, which fortunately is falling into disuse. Then again the cervix is, at the present day, often dilated by tents or by graduated bougies; but the former is dangerous, and both are painful, tedious, and unsatisfactory.

The operation which I can recommend to you most highly, and one which I shall now perform on our patient, is that of forcible dilatation. The instruments which I use are two modified Ellinger dilators of different sizes, made under my supervision by Messrs. J. H. Gemrig & Son, of this city. Ellinger's model is the best on account of the parallel action of the blades, which dilate the whole track of the canal uniformly. The smaller of these dilators has slender blades, and it pilots the way for the other, which is more powerful, having blades that do not feather. The lighter instrument needs only a ratchet in the handles, but the stronger one should have a screw by which the handles are brought together. Lest the beak should hit the fundus uteri and seriously injure it when these instruments are opened, their blades are made no longer than two inches, and are armed with a shoulder which prevents further penetration. The larger instrument opens to an outside width of one and a half inches, and its blades are roughened, or corrugated, by shallow grooves in order to keep them from slipping out. This dilator has also a graduated arc in the handles by which the divergence of the blades can be read off.

In a case of dysmenorrhœa, or in one of sterility from flexion or from stenosis, as in the woman before us, my mode of performing the operation of dilatation is as follows: The patient is thoroughly anæsthetized, and a suppository containing one grain of aqueous extract of opium is slipped into the rectum. She is then turned on her back, and drawn to the edge of the bed, each knee being supported by an assistant. The light must be good, so that the operator can see what he is about. My bivalve speculum being now introduced, the vagina is well swabbed out with a five per cent. solution of carbolic acid. By the aid of a strong uterine tenaculum, the cervix is steadied and the smaller dilator is introduced as far as it will go. Upon gently stretching open that portion of the canal which it occupies, the stricture above so yields that, when the instrument is closed, it can be made to pass up higher. Thus by repetitions of this manœuvre, little by little, in a few minutes' time a cervical canal is tunnelled out which before could not admit the finest probe. Should the os externum be a mere pinhole, or it be too small to admit the beak of the dilator, it is enlarged by the closed blades of a pair of straight scissors, which are introduced with a boring motion. As soon as the cavity of the womb is gained, the handles are gradually brought together, and allowed to stay so for one or two minutes. The small dilator being now withdrawn, the larger one is introduced and the handles are then slowly screwed toward one another. If the flexion be very marked, this instrument after being withdrawn, should be reintroduced with its curve reversed to that of the flexion, and the final dilatation then made. But in doing this the operator must take good care not to rotate the womb on its axis, and not to mistake the twist for a reversal of flexion. The ether is now withheld and the dilator kept *in situ* some fifteen minutes, when it is closed, removed, and the vagina well syringed out with the same solution of carbolic acid. Occasionally a slight flow of blood will last for several days after the operation, simulating the menstrual flux. Often the flux is precipitated or it is renewed, if the operation follows or precedes it too soon. The best time for dilatation is, therefore, midway between two monthly periods. Were the case before us a retroflexion, I should, after the dilatation, put in a pessary long enough to span the angle of flexure. This never fails to straighten out the womb, and in time to restore it.

Although this operation looks like rough work when compared with the neat, but most dangerous cutting one, our patient will probably need not more than two suppositories, and she will complain merely of soreness for one or two days. To forestall any tendency to metritis, she will be kept in bed until all tenderness has disappeared. Pain will be met by rectal suppositories of opium, and by large poultices laid over the abdomen. From this operation I have seen only slight pelvic disturbance, but it has always been readily controlled and has not given alarm. In one case of dilatation complicated by a fibroid of the womb, a uterine colic lasted for several days, but it was finally subdued by asafœtida in large doses, and never became inflammatory. Should the temperature rise and symptoms of pelvic inflamma-

Digitized by Google

tion appear, the ice-bag should replace the warm poultice. But I have not yet met with a temperature high enough to need this energetic mode of treatment.

In the great majority of cases I dilate the canal not to the fullest extent of the larger instrument, but, as in the case before us, to one and a quarter inches. Sometimes, in an infantile cervix, which does not readily yield and might give way, the handles are not screwed closer than three-quarters of an inch or an inch; but this is exceptional. Tearing of the cervix has happened in four of my cases; in two from the sudden slipping out of the beak, and in two from sheer stretching. Three of these were unmarried and the cervix in each was split posteriorly, nearly half-way to the vaginal junction. The rent looked exactly like the incision of the cutting, or bloody, operation, but it was only half the length of the latter. As it kept the os externum patulous and could not do any mischief, I did not sew it up. The fourth case was that of a multipara, whose uterine canal had been nearly closed up by applications of silver nitrate, made by her physician with the view of curing what he supposed was an "ulceration of the os," but which was a bilateral laceration. The tissues, rendered cicatricial and brittle by the caustic, were torn by the dilator for about half an inch on the right side. Here the hemorrhage was free enough to need styptic applications and a light tampon. I could have stopped it by wire sutures, but this was not done, as it would have defeated the object of the operation.

For slight dilatations, such as for the office treatment of anteflexions and of stenosis, or for the introduction of the curette, or of the applicator armed with cotton, the more delicate instrument is quite strong enough, and an anæsthetic is not needed. I also use it in women who object to taking ether; but the operation is then very painful and it has to be repeated several times, while the results are by no means so good as when the canal has been dilated by the larger instrument, and under ether. Occasionally in virgins, in order to save the hymen, I have dispensed with the speculum and have dilated with the more slender instrument, passing it in along my finger; but this cannot always be done, and it is usually unsatisfactory. I was led to this, because on one occasion I was asked to give a certificate of virginity—in other words, to write and sign a paper stating that before the operation the hymen was intact. I also had to do this in the case of an unmarried woman, whose perineum, in spite of lateral cuts, was badly torn in my efforts to deliver with the obstetric forceps a very large fibroid tumor of the womb. When she returned home, the village crones got up such a buzz of scandal, that I had to go to her defence. Sometimes in a very sharply anteflexed womb, the dilator cannot be made to pass the os internum. This difficulty is overcome by first passing in a surgeon's probe, and then, along it as a guide, the dilator.

After a forcible dilatation under ether, the cervical canal rarely returns to its former bent or former narrow condition. Since lateral extension of elastic bodies antagonizes their length, the cervix shortens and widens, and the exudation provisionally thrown out by the submucous lesions sustained by the dilated part, serves still further to thicken and stiffen its tissues. In other words, the stem-like neck of the pear-shaped womb is shortened, widened, strengthened, and straightened. Hence for straightening out anteflexed or congenitally retroflexed wombs, and for dilating and shortening the canal in cases of sterility or of dysmenorrhœa arising from stenosis or from a conical cervix, the dilator will be found a most efficient instrument. Sometimes in sharply bent wombs, I put in a stem-pessary immediately after the dilatation. In retroflexions I always put in a pessary long enough to span the angle of the flexion, so as to straighten the womb, by making pressure on the fundus. To this occasionally a stem-pessary is added.

In its results this operation is not an infallible one. I have thrice been obliged to repeat the dilatation, and would like to do so in several cases did the women permit. In a very few cases I have been forced, as a final resort, to nick a pinhole os externum. But I had not then learned how far I could safely stretch open the uterine canal, and the operation of dilatation was, therefore, not so efficiently performed by me as it is now through a larger and riper experience.

It is not to cases of sterility or of dysmenorrhœa only that rapid dilatation should be limited. As before stated, I use it to stretch open the canal for the admission of the curette and of tents, or for the purpose of making applications to the uterine cavity.* In cases needing irrigation of the uterine cavity, I first dilate the canal with the slender instrument, and introduce the nozzle of the syringe between the separated blades. This gives a free avenue for the escape of the liquid, and robs of its dangers this form of intrauterine medication. I also resort to the dilator in order to explore the womb with the finger. For instance, in a given case of menorrhagia in which a polypus or some other uterine growth is suspected, in order to avoid the delay and the dangers inseparable from the use of tents, I put the woman under an anæsthetic, and, after the rapid dilatation of the cervical canal to the utmost capacity of the instrument,—viz., one and a half inches,—am enabled to pass my finger up to the fundus. This is accomplished either by drawing down and steadying the womb by a volsella forceps fixed on to the anterior lip, or, in thin subjects, by forcing the womb down upon the finger through suprapubic pressure on its fundus. In this way I have, over and over again, at one sitting discovered a uterine growth, twisted it off, and removed it. Usually in these cases more difficulty has been experienced in removing the polypus or other growth through the narrow canal, than in twisting it off from its uterine attachment. It often has to be wire-drawn before its removal can be effected, and sometimes it will be found needful to enlarge the os uteri by a few nicks. Usually, when the menorrhagia has been free, the cervical tissue is so lax that, after dilatation, the index-finger can penetrate the canal and reach the fundus, but sometimes only its tip can be made to pass the os internum. Yet even this limited degree of penetration is commonly quite enough to decide the presence of an inside growth. If it be not enough, I invariably search for the growth with a small pair of fenestrated forceps, and I have repeatedly seized and removed one, the existence of which was merely suspected. After such operations the uterine cavity and the vagina are thoroughly washed out with a two and a half per cent. solution of carbolic acid.

I am sorry to say that I have not kept full records of all my cases of rapid dilatation. For instance, I have

Digitized by Google

rarely tabulated office cases of dilatation, in which ether was not given. Nor has any note been made of cases in which dilatation was performed under ether for curetting, for digital exploration of the endometrium, or for the removal of uterine growths. I have tabulated merely cases of dysmenorrhœa, in single or in married women. In the married, with but three exceptions, which will be noted in the proper place, painful menstruation was associated with sterility.

Including all the cases of dilatation performed under ether, I must have had nigh three hundred and fifty cases. I have limited myself to these cases because the use of an anæsthetic implies full dilatation—one in which serious injury, if ever, would most likely be sustained. Yet, there has not been a death or a case even of serious inflammation, in my practice, and the results have been most satisfactory—far more so than when the cutting operation was performed by me.

Let me read to you a brief abstract of the statistics of my cases of dysmenorrhœa: Of single women, there were one hundred cases; of married, one hundred and nineteen; making in all two hundred and nineteen. Of the unmarried, twenty-four were unheard from after the operation, leaving seventy-six from which any data could be obtained. Of these, forty-five cases were virtually cured; twenty-four more or less improved; and seven were not at all improved. Of these seven that were not benefited by the operation, five subsequently had their ovaries removed—one of them by another physician, and four by myself: of the latter, one died. In each one the ovaries had become so changed by cystic or by interstitial degeneration as to make the dysmenorrhœa otherwise incurable. Of the twenty-four improved, there was one on whom oöphorectomy was also performed; for, although the dysmenorrhœa was partly relieved by dilatation, ovarian insanity and menorrhagia were not. The operation was a successful one, and my patient was not only cured of her hemorrhages, but she regained her reason. Out of these cases, the majority, although not wholly cured, were greatly improved. For example, one of them was formerly bedridden during the whole period of her menstrual flux, and had then to take large doses of morphia. She also suffered at those times from hæmatemesis and epistaxis. Since the operation she experiences pain for merely two hours, needs no anodyne, and has lost her ectopic hemorrhages. Her gain in health and flesh has been great. Another one, who was wholly crippled by her sufferings and made nervous by the dread of them, is now a busy nurse. For one hour at every period she suffers acutely, but not enough to overcome her dread of taking ether and of having a second dilatation performed.

Of those cured, two had Sims's cutting operation performed previously without benefit, and were afterward dilated; three were dilated a second time before a cure could be effected. The word "cured" in some of these cases, does not mean that the women were wholly free from any pain whatever, but that they did not suffer sufficiently either to go to bed or to take any stimulants or anodynes. The history of several cases merits more than a mere allusion. The sufferings of one of my patients at every monthly period had always been great, but while she was at a boarding-school they grew so excruciating as to cause furious delirium at those times. This finally culminated in permanent insanity, with suicidal impulses. While in this condition she was placed in my hands. After rapid dilatation of the cervical canal, the dysmenorrhœa wholly disappeared. The exemption from pain toned down some of her more extravagant delusions, but she did not wholly regain her reason until a few months afterward. She is now free from all menstrual pain, and is in the complete possession of her mental faculties.

A Hebrew lady, whose health had suffered from dreadful dysmenorrhœa, was so greatly improved by one dilatation, that her physician and her friends were amazed at her rapid restoration to health. Not long afterward the doctor asked me to perform the same operation upon another one of his patients, who was, if anything, worse. Her sufferings were so severe that he wrote, "I fear that another period might kill her," and urged an immediate operation. The cervix in this case was conical and very dense. Fearing a tearing of the parts, I screwed the instrument very slowly up to one inch and a quarter, and kept up this amount of dilatation for some twenty minutes. The cervix did not sustain any injury. The canal has since stayed open, and she is free from all menstrual pain. Another case was that of an unmarried lady, sent to me from a distant State, whose sufferings at her periods were so great that morphia, however administered, was not potent enough to allay them, and her nervous system became very much shattered. Finally, at her last monthly, she was compelled to have two physicians in attendance on her, who took turn about in administering chloroform night and day for forty-eight hours. This experience decided them to send her to me. One dilatation of an inch and a quarter wholly cured her.

Of the married, sixty-nine were heard from. Of these, forty-seven were virtually cured, eighteen improved, and four unimproved. Out of these sixty-nine cases, eleven were not in a condition to conceive: four of them from fibroid tumors of the womb, two from destructive applications of silver nitrate to a torn cervix, three from being over forty-one years of age, and one from being a widow. This leaves but fifty-eight capable of conception, and of these, eleven, or about 19 per cent., became pregnant. But the ratio is, in fact, larger, for I know that several of my patients, fearing pregnancy, employed preventive measures after the operation, and I suspected several others of doing the same thing. Then, again, I believe that yet others, who consulted me merely for painful menstruation, have not reported their subsequent pregnancies. For instance, of the eleven cases of pregnancy, five came to my knowledge incidentally and not directly from the ladies themselves. It is not much more than a year ago that I learned, by the merest accident, the subsequent history of a clergyman's wife, whose cervical canal I had dilated six years ago. She had been making up for lost time by giving birth to twins within a year after the operation, and later to several other children. She had been married eight years before she came to me, and had had her cervical canal dilated by tents and slit up with Peaslee's metrotome by a skilful surgeon.

One word more: While you can expect much from this operation whenever it is performed for dysmenorrhœa caused by flexion or by stenosis, you cannot be so sanguine with regard to its results in sterility. The

Digitized by Google

reason of this is, that sterility associated with dysmenorrhœa often leads to such tissue changes in the womb as in time to make it incapable of forming a nest for the ovum, which, therefore, either escapes or perishes.

ORIGINAL ARTICLES.

EXTRAUTERINE PREGNANCY CHANGED TO INTRAUTERINE, BY MEANS OF FARADIZATION.

BY HENRY J. GARRIGUES, A.M., M.D.,
VISITING OBSTETRIC SURGEON TO THE MATERNITY HOSPITAL, GYNECOLOGIST TO THE GERMAN HOSPITAL, ETC., NEW YORK.

IN a paper read before the American Gynecological Society, in 1882,[1] I could already compile ten cases of extrauterine pregnancy treated with electricity, besides a new one treated by myself in that way. Since then many cases have been published in medical journals and transactions of societies in this country, and one in Europe by Dr. Hochmann,[2] of Strassburg, which possesses particular interest, in that static electricity was used with perfect success to kill the fœtus as late as six months after conception.

The success has been so uniform that this treatment has been fully established as *the* treatment in this country, and it is only about minor details, such as the kind of electricity which is to be preferred, the duration of the application, the maximum development of the fœtus in which it is applicable, and the varieties of extrauterine pregnancy in which it ought to be used, that competent men yet entertain different opinions. These questions can only be definitely settled by accumulated experience, and in the present state of our knowledge it would be premature to lay down strict rules. This much is sure, that electricity in all cases, in this country, has proved a certain and safe remedy in the earlier months of extrauterine pregnancy. As to safety, it is especially to be extolled in comparison with the method of injection of morphine, which seems to be preferred in Europe. It is true, that none of the patients treated by the latter method died, but in all recovery was very slow, and in several the patient was at times in a precarious state. Friedreich's first case took a month, the second eight months, and the patient was at times decidedly hectic. Kœberlé's had a hemorrhage. Rennert's patient was under treatment during two months, and was seriously ill. In Fournier's case grave inflammatory accidents occurred, and he was obliged to have recourse to laparotomy.[3]

This time, however, I do not wish to discuss the merits of the electric treatment of extrauterine pregnancy. I only want to put on record a very curious case which recently was treated by me, with the unexpected result of changing a previously diagnosticated interstitial pregnancy into an intrauterine. It may be remembered, that already one case of this kind has been reported, namely, that of Drs. Charles McBurney, T. G. Thomas, and T. A. Emmet, the sixth in my above mentioned article, but that ended in abortion, while mine went on till the first half of the eighth month, when a child was born that lived seven hours, and might probably have survived if proper care had been taken. The details of the case are as follows:

Mrs. Sophia B., æt. 20, born in Russia, was confined for the first time, March 9, 1884. A finger-thick band, situated in the median line just below the os, had to be cut. Labor continuing tedious, she was delivered with forceps, the head presenting by the vertex in the right occipito-posterior position. She had a severe attack of diphtheritic vulvitis, vaginitis, and metritis. She became pregnant a second time in June, suffered much during the next four months, and had a premature delivery on January 1, 1885. In March began her third pregnancy, which interests us particularly here.

She menstruated for the last time, from the 18th till the 21st of March, 1885. On the 20th of May, she consulted me for dull pain in the right iliac fossa. The vagina had a lilac color; the uterus was scarcely enlarged in the median line, but presented at the part corresponding to the right upper angle a swelling without definite limits, and very tender on palpation. No vaginal pulsation.

On June 17th I saw her again. During the intervening four weeks the pain had increased very much. The uterus had grown, but preserved its irregular shape. On the right side the distance from the fundus to the pubic bone was four inches; on the left, three and a half. The right half was very tender on pressure, the left did not present any increased sensibility. The swelling had increased much in size, and filled the right side of the pelvis. The right half of the uterus was large and merged into the said swelling, the left was comparatively little enlarged. She had some shooting pain in the breasts, which were turgescent. Five days later, June 22d, at 10 A. M., she was seized with so violent pain that she thought she was going to have an abortion, and sent in haste for a midwife. I saw her at 3 P. M., and found the cervix closed, but soft, and giving the impression that it was going to dilate. All over the uterus, inclusive of the swelling, was heard an uncommonly strong uterine souffle. I distinctly felt that the left half of the uterus was flat, while the right half, together with the said swelling, formed a spherical mass. I explained to the patient and her husband that, in my opinion, she had an interstitial pregnancy in that part of the right Fallopian tube which lies in the wall of the uterus; that if I was mistaken, and the ovum was developed in the cavity of the uterus, an abortion was imminent; and that, therefore, the introduction of a sound into the uterine cavity could not do any harm, and would give important information in regard to the question of extrauterine pregnancy. Having obtained their consent, I introduced the sound to a depth of three inches and a half. It entered with the greatest facility, without meeting any resistance. It could easily be turned to the left, but when turned to the right it soon met resistance. There did not come any fluid, neither

Digitized by Google

blood nor liquor amnii. This confirmed me in my diagnosis of right interstitial pregnancy. The pain was provisionally quieted with morphine, while I made preparations for the use of electricity. When I saw her again at 8 P. M., there was some bloody discharge from the uterus, but the cervix was unchanged. The faradization apparatus, which I had used with marked success in my previous case of tubal pregnancy, being at the instrument-maker's for repair, I bought a Smith & Shaw's closed cell pocket battery, applied the negative pole, consisting of a metal ball covered with muslin, against the tumor in the vagina, and the positive pole, formed by a large plate of carbon covered with canton flannel, on the abdomen just above and in front of the tumor. I used the lowest power of the primary current of both cells for ten minutes. The pain was quite supportable. Before beginning, I mapped out the whole uterus on the abdomen with ink, and later I went over the line with a stick of lunar caustic. It formed an obliquely oblong figure, five inches wide, three inches and a half high. Only two inches of the width lay to the left of the median line, three to the right. She did not sleep during the night on account of excitement, but had not much pain.

The next morning, June 23d, I found all uterine souffle had disappeared. The uterus was much smaller and softer, the change having taken place only in the right side. The uterine body measured now four inches in width, two on either side of the median line, and two and three-quarters of an inch in height. The cervix was unchanged. Nothing had been discharged from the vagina except a few drops of pure blood, no water, no shreds, no lumps. The breasts had become much flatter. Pulse and temperature were normal. Faradization as the evening before. During the day she had some vomiting, headache, and feeling of malaise.

The next morning, June 24th, the headache had disappeared, and she was free from pain, and was not even tender on pressure, except on the place corresponding to the fœtal sac.

On the following day (June 25) she felt quite well, and began to eat. The cervix was more closed than heretofore, and the whole uterus had sunk a little in the pelvis.

On the following day (June 26) the tenderness on vaginal examination was much diminished. In the lower part of the uterine body, mostly to the right, was felt a harder, somewhat kidney-shaped part, measuring two and five-eighths inches from side to side, by one and five-eighths in height (fœtus?).

During the following days this mass became less distinct, and after three days it could no longer be distinguished.

On July 1st, the tenth day of treatment, the uterus had again risen somewhat out of the pelvis, and measurements showed that it had increased both in width and height. By rectal examination in the left side decubitus, a soft, elastic, tender swelling, of the size of an English walnut, was felt behind the uterus, somewhat to the right (small ovarian cyst?). An artery was felt pulsating in the recto-vaginal septum.

For safety's sake, I applied faradization as above, on July 2d, 3d, 4th, and 5th. The patient felt perfectly well, and all tenderness on pressure had disappeared.

During most of July and August I was absent, and Dr J. C. Colles took care of the case.

On July 14th she said she felt as if that part of the uterus which lay to the left was growing, and that she had felt movements similar to those experienced in the fourth month of her previous pregnancies.

On July 17th she complained of quite severe pain in the lower part of the abdomen. The womb was evidently enlarged in all directions, but of regular shape. Faradization was used as before on the 17th and 19th, with the effect of stopping both pain and movements, and diminishing the size of the womb.

On the 23d of the same month I came on purpose to the city from a long distance, to examine this remarkable case. I found the uterus forming a regular globular body of considerably larger size than when I had seen it last, eighteen days before. The fundus reached five and three-quarters inches above the symphysis pubis, and five inches from side to side. The uterine souffle had reappeared, but no fœtal heart sounds or movements could be heard.

On July 27th she again felt the fœtus move.

On August 20th the fundus had approached the umbilicus to within a finger's breadth.

On September 2d I saw her again. The fundus was at the umbilicus. Fœtal movements could both be heard and felt, and the fœtal heart sounds were heard in the lower part of the uterus, to the right. She felt well, and continued to do so till the end of the next month.

On October 31st, at one A. M., she was seized with labor pains, sent for a neighboring midwife, and an hour later, by a normal delivery, gave birth to a well-developed female child measuring sixteen and one-half inches in length, and looking as if it weighed between five and six pounds. It lived five hours, and might probably have continued to do so if better taken care of. The parents had the old superstition, that "an eight months' child could not live." When I saw it eight hours after its birth, it had not even been washed. The after-birth was small, but otherwise of normal appearance.

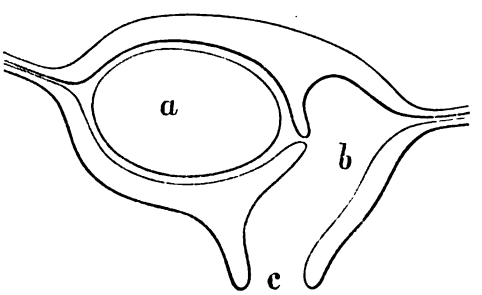
Commentary.—When we look over the chief features of this case, we find, first, her severe diphtheritic inflammation of the womb, which may have obliterated the uterine end of the right Fallopian tube. In the intervening pregnancy, the ovum may have come through the open left tube, while in the third it came through the right, and was arrested in that part of the canal which lies in the uterine wall. Thus we have in her previous ulcerative metritis a predisposing cause of extrauterine pregnancy.

Even when I examined her for the first time, when she could be only eight weeks pregnant, the presence of the swelling in the right upper angle of the uterus, and the shape of the uterus were so peculiar, that I surmised it might be an interstitial pregnancy. A month later the difference in size, shape, and tenderness of the two halves of the uterus was so marked that I had a strong suspicion that I had such a case before me. When, a few days later, just at the end of the third month, she was seized with violent pain, which she referred to the womb, and

Digitized by Google

which she took for a commencing abortion, for which she sought help as quick as possible, there was not much doubt in my mind as to the diagnosis, and when I could introduce a common uterine sound three inches and a half through a patulous os, and turn it without the escape of any fluid, I think that was conclusive proof that the uterine cavity was enlarged, but empty.

I have asked myself the question, If it were not possible that the ovum might have been engrafted on the mucous membrane of the uterus close up to the right tube, and that coalescence between the decidua reflexa and vera had not yet occurred, so that the sound might have entered the space between the two? I have treated an abortion case in which the decidua had a prolongation like the finger of a glove, corresponding to one horn of the uterus. But, apart from real uteri bicornes, this shape of the uterine cavity, like a star with three rays, is only found in nulliparous women. In those who have borne children, the cavity becomes triangular and the horns much shortened.[1] Now our patient had an entirely normal uterus, as I have had the opportunity to ascertain many times both in the pregnant and non-pregnant condition. Furthermore, the sound was introduced when she was at the end of the third month. She stated that coition had taken place immediately after the cessation of the menstrual flow on March 21st, and the whole development of the uterus and the child corresponds to this starting-point. At that period of gestation the reflexa and decidua are in contact, and could only be separated by injection of water or insufflation of air.[2] In my case the sound entered with the greatest ease through a patulous cervix into an open cavity. It was in the median line, and could be turned to the left without meeting resistance, and somewhat to the right, when it was arrested by the large body situated in the right wall and bulging into the uterus. The condition found at the time of sounding may be represented by the following diagram.



a. Fœtal sac developed in uterine portion of right tube.
b. Uterine cavity.
c. Os uteri.

We can no longer doubt the possibility of a tubal, and especially an interstitial, pregnancy being changed into a uterine. The above mentioned case occurring in Dr. McBurney's practice, was diagnosticated by two gynecologists of such eminence as Drs. Thomas and Emmet. Before the use of electricity a tumor was felt overhanging the edge of the true pelvis, and extending beyond about two inches. After the second application there was bloody discharge. The tumor in the left iliac fossa disappeared with the exception of a small mass on the brim. In the median line, on the other hand, was felt a smooth, symmetrical tumor, and from the vagina was felt a tense and very strong bag of membranes protruding through a fully dilated cervix. On rupturing the membranes, a large amount of pure liquor amnii, and with it a dead fœtus about three months old, came away. The placenta followed in about twenty minutes.

Dr. Janvrin,[1] for many years assistant gynecologist to the New York Woman's Hospital, has reported a case which in some respects is very much like mine. Forty-nine days after the only coition that had taken place the uterus was found a little enlarged, the os was slightly patulous and considerable tenderness existed over the left horn and tube. Later a symmetrical enlargement was found of the left tube, being as great at the junction with the uterus as at any other point. He used considerable force in pressing upon the fœtus, trying to expel it into the uterus, but failed. During the night the patient had severe pains, like those of labor, confined to the left side of the uterus and to the tube, and at the same time there was a slight flow. The next morning the mass had disappeared from the tube. At all of his previous examinations the right horn of the uterus was much flattened, but within the last twenty-four hours the right side had become bulging, almost as much as the left horn. The fœtus was retained in the uterus till the end of the fourth month, but when it was expelled it had the appearance of only two months' development. The placenta was atrophied, except at one point as large as a thumb-nail, where it was fresh.

Those two cases were observed by accoucheurs and gynecologists of large experience, and go far to corroborate the view that in the present case likewise a tubal pregnancy was changed into an uterine; but mine differs from the others by the continued life and development of the fœtus.

Particular interest attaches to the question, how electricity acted in this case? Are we to conclude that electricity cannot be relied on as a fœticide? By no means. As stated above, the apparatus I had used on a previous occasion, and which was a one-cell carbon and zinc apparatus, with Bunsen's bichromate of potash solution, was not available. Instead of that, I used a Smith & Shaw closed cell battery, in which electricity is generated by the immersion of a zinc rod into a solution of bisulphate of mercury. I have since then found that this apparatus causes considerably more pain than the other, and, as I only used the sensation of the very nervous patient for a guide as to the strength of the current to be applied, it is evident that she got much less electricity than she would with the other apparatus, and much less than the amount used on my first patient, who was an uncommonly apathetic per-

Digitized by Google

son. The small amount of electricity passed through the fœtus explains why it did not die. Dr. Landis's experiments with insects, fishes, and rabbits, have proved that if the current is not strong enough, and not applied sufficiently long, the animal is only stunned and revives after a while.[1] In our case the length of the sittings was the one that commonly has been used, namely, ten minutes each time. That the fœtus withstood eight such applications can, therefore, only be referable to the weakness of the current.

I have hitherto believed that electricity acted primarily by killing the fœtus, and that all the other phenomena observable were of a secondary nature. But this case proves that it is not so. Here the fœtus was not killed, and yet we had a most marked effect of the application of electricity. During the application nothing peculiar was observable, except very moderate pain. No muscular contractions were seen or felt, and the womb neither decreased in size nor changed in shape. But when I saw the patient again, only twelve hours later, very remarkable changes had taken place. The bulk of the uterus had diminished one-third, which can only be explained by absorption of the liquor amnii, for nothing had came through the vagina except a few drops of pure blood. The severe pain had almost ceased, and the strong uterine souffle had entirely disappeared, both of which changes find a natural explanation in the diminished tension of the uterine wall. The womb had become much more symmetrical, which I ascribe to the removal of the ovum into the cavity. A few days later a mass, which, doubtless, was the fœtus, could be felt in the lowest part of the uterine body. With regard to the latter point, it may be worth mentioning that, according to the most approved views on placenta prævia, that condition is due to arrested abortion,[2] the placenta being thrown off from its attachment in the upper part of the womb, and finding a new one above the internal os. When in this way the ovum is detached, and has to engraft itself in a new place, we can understand that in the majority of cases it will fail to do so, and the process ends in abortion, as in Dr. McBurney's case; and that, if it really succeeds, it is less favorably situated than if it had been developed from the beginning in its new abode. This would explain why in Dr. Janvrin's case the fœtus, although retained in the uterus for two months after its migration, did not progress in development, and why the placenta was normal only on a small spot. In our present case development went on till the first half of the eighth month, but the placenta was small.

Even in the breasts the usual change from turgescence to flaccidity took place at the first application of electricity.

A month later, after movements had been felt, electricity was applied twice. This time there were again diminution of size of the uterus, cessation of pain, and cessation of fœtal movements for a whole week. The condition of the breasts was not noted.

We see, then, that, although the fœtus was not dead, but merely stunned, many remarkable changes took place in the womb and in the breasts.

We notice in the history that a slight discharge of blood occurred even before the application of electricity, and continued the next day. This, together with the violent labor-like pains, shows that a destruction of the obstacle which stood between the fœtal sac and the uterine cavity had begun. Electricity may be supposed to have made the removal easier by diminishing the bulk of the ovum to be dislodged, and was thus, perhaps, the factor which prevented miscarriage taking place at that time.

The practical value of this experience will, probably, be rather limited. In abdominal and true tubal pregnancy the indications will be, as heretofore, to try to kill the fœtus as soon as possible by means of a strong current; but, in the tubo-uterine variety, it might be worth while trying by means of a weak current merely to facilitate the removal from the cavity in the wall into the interior of the uterus, where, under favorable circumstances, it may form new connections, and be developed sufficiently to allow a living and viable child to be born.

THE THERAPEUTIC ACTION OF THEINE; A NEW ANALGESIC.

BY THOMAS J. MAYS, M.D.,
OF PHILADELPHIA.

THEINE is the active principle of the leaves of Chinese tea, and is generally reputed to be identical with caffeine, both in chemical composition and in physiological action. In a series of experiments, which appeared in the *Therapeutic Gazette* for September, 1885, I think I produced sufficient proof to show that it differs very markedly in its physiological action from that of caffeine; and I have since then gathered evidence to indicate that it differs as widely from the clinical action of caffeine as it does from its physiological action. In fact, caffeine principally affects the motor nerves, while theine chiefly influences the sensory nerves, and clinically proves itself a most valuable analgesic, surpassing morphia in promptness and permanency in relieving pain in some affections, without producing any, or at least very little, disturbance of the general nervous system.

In the experiments referred to, I drew the following conclusions concerning the general physiological action of theine: It paralyzes sensation before motion; it impairs sensibility from the centre to the periphery, and not, like brucine and cocaine, from the periphery to the centre; it produces convulsions which are spinal and not cerebral; it has a more powerful action on the sensory nerves, and less on the motor nerves than caffeine.

Its power to produce such decided and complete paralysis of the sensory nerves in the lower animals gave rise to a desire to test its physiological properties on the healthy human being, and, with this end in view, I introduced moderate, or probably small doses of the drug into the circulation by the subcutaneous method in a number of instances, and noted the results. In the main, there was a general agree-

Digitized by Google

ment in the symptoms which developed, and hence, only one case, typical of the rest, will be given here. It was injected into the left forearm of an adult in good health, whose arm, however, was fatigued by carrying a satchel to railroad station the previous morning.

1.40 P. M. Injected $\frac{1}{5}$ grain of theine in left forearm, near elbow.
1.42. Fatigue in arm gone.
1.43. Diminution of sensibility in left forearm, especially around seat of injection.
1.46. Diminished sensibility extends as far as hand.
1.48. Some burning at seat of injection.
1.49. Touch impaired in tips of fingers of left hand.
1.51. Tingling in fingers and wrist of left hand.
1.52. No influence on pupil.
1.54. Voluntary motion of arm and hand unimpaired.
1.55. Arm and hand feel as if they were asleep.
1.56. No burning around seat of puncture.
1.57. Marked difference in sensibility between the two arms and hands.
2.02. No impairment of sensation above elbow.
2.03. Slight shooting pains along the posterior part of left arm above elbow.
2.06. Sensibility of finger tips impaired.
2.07. Pupils unaffected.
2.08. Finger tips very dull.
2.11. In playing the piano, can move fingers of left hand as well as those of right.
2.13. Mind perfectly clear.
2.15. Pulse 78.
2.16. Same difference in sensibility between hands and arms.
2.23. Pulse 74, and stronger.
2.26. Pupils not affected.
2.30. Sensibility absolutely gone around seat of injection.
2.32. Pulse 74.
2.33. Motion in left arm unimpaired.
2.34. Fingers and hands feel as if asleep.
2.40. Pupils unaffected.
2.44. Left hand numb.
2.55. No difference in temperature between two hands.
3.00. Pupils unaffected. Mind clear. No stupor.
3.01. Finger tips very numb.
3.06. Feels a little sleepy.
5.30. Sensibility still impaired, especially in finger tips. Arm above elbow uninfluenced.
6.40. Sensation more normal in arm. Finger tips still feel numb.
8.00. Sensibility entirely restored. There are some redness and tenderness around seat of injection.

These experiments confirm those which I made on the lower animals in the following particulars: Theine has a special affinity for sensation, and not for motion. It produces anæsthesia in the injected limb, which is confined below the seat of injection—*i. e.*, its influence extends from the centre to the periphery, and not in the opposite direction.

The products of all these experiments have led me to believe that theine would be efficacious in the treatment of painful affections of the long nerves, and I am able to state that this deduction was fully verified by the results which were obtained in the only two cases in which I had the opportunity of testing it. These two cases are the following:

CASE I.—Mrs. A. A., aged 49 years, came under my care May 2, 1885, when she had constant pain in right leg from hip to foot ever since the preceding Christmas. The pain followed the course of the nerves of the leg, and, of course, was very much aggravated by walking. The leg was considerably atrophied, and was weak and uncertain in its gait. Her appetite was poor, and bowels irregular, and she passed whole nights without sleep on account of pain. She was anæmic, and was treated with iron, quinia, ammonia, salicylate of sodium, iodide of potash, atropia, morphia, poultices, blisters, etc., without avail, until the following 18th of July, when I injected $\frac{1}{5}$ grain of theine into the calf of her leg. The pain ceased in less than five minutes, and never returned in its original force. In half an hour her heel and foot began to feel numb and insensible, which lasted for about twelve hours, but her mind was perfectly free from its influence. She experienced no headache, or drowsiness.

July 20.—Pain in whole leg better since last injection, but has not entirely disappeared from the thigh, so I introduced $\frac{1}{5}$ grain into the latter region.

28th.—Leg altogether free from pain, but still complains of some in foot. Otherwise, she is improving. Injected $\frac{1}{5}$ grain over instep.

September 6.—Feels better. Slight pain around ankle-joint. Injected $\frac{1}{10}$ grain more at this point. This was the last injection she received, and she made an uninterrupted recovery from this time on. The leg began to fill out, and at the present writing it is of the same dimensions as the left. She experienced no bad results from the theine injections, neither at the seat of injection nor anywhere else, except a few slight muscular twitchings in the leg after the first two injections. She expressed herself as being highly pleased with the result.

CASE II.—E. P——, aged 19 years, was suffering from pain in right shoulder extending from right side of spinal column along the arm to the tips of her fingers. The pain had been very annoying and frequently kept her awake at night. On examination, I found great tenderness on pressure over right brachial plexus, which extended down the arm of same side. She was anæmic, had dysmenorrhœa, and was treated by me with iron, quinia, and ammonia without any benefit, so far as the neuralgia was concerned—in fact, she said the pain was worse. On September 29, 1885, at 8.45 P. M., I injected, hypodermically, $\frac{1}{5}$ grain of theine over right brachial plexus. At 8.50 she said she had a feeling as if something was creeping over her right shoulder toward the arm. On examination, found sensation around point of injection, and over region where she experienced the formication, somewhat diminished. At 8.55, in ten minutes, she said that the neuralgic pain in the back was relieved. At 9, in fifteen minutes, the diminution of sensibility had extended

Digitized by Google

from shoulder down arm. At 9.02, in twenty minutes, anæsthesia marked around seat of injection. Her head feels good and clear. At 9.15, in thirty minutes, neuralgic pain improved in fingers. At 9.17, in thirty-two minutes, still feels the creeping sensation over right shoulder. Sensation slightly impaired from shoulder to end of fingers.

September 30.—Slept well until 3 A. M., after which she was somewhat restless, but experienced no pain.

October 1.—No return of pain. Experienced no stupor or unpleasant sensation throughout experiment.

From the results of the action of theine in these cases it will be seen that it is a powerful anodyne without producing any intoxication of the higher nerve centres, which is so common with morphia and all other agents belonging to this class. Its influence is both quick and persistent, and it manifests an almost exclusive affinity for the sensory nerves. It relieves pain by acting from the centre toward the periphery, and showing its effects but very seldom above the seat of injection. This is precisely in harmony with what was found in the experiments on the lower animals. In $\frac{1}{10}$, $\frac{1}{8}$, and even $\frac{1}{3}$ grain doses it is entirely free from dangerous consequences—the only inconvenience which it causes is a slight, but transient burning at the point of introduction. I use a one per cent. watery solution of Merck's preparation —ten minims of which equal one-fifth of a grain of theine. Larger doses are required in some individuals in order to bring out its characteristic action.

I sincerely hope that the action of this agent will be further investigated, for, if the favorable report above given is sustained, it will certainly prove itself of the greatest clinical value, and will be a vindication of the modern methods of pharmacological inquiry.

1716 CHESTNUT STREET.

DISINFECTANTS.

REPORTS OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

XXII.

CONCLUSIONS.

THE experimental evidence recorded in these reports seems to justify the following conclusions:

The most useful agents for the destruction of spore-containing infectious materials are:

1. Fire. Complete destruction by burning.
2. Steam under pressure. 110° C. (230° Fahr.) for ten minutes.
3. Boiling in water for one hour.[1]
4. Chloride of lime.[2] A 4 per cent. solution.
5. Mercuric chloride. A solution of 1 : 500.

For the destruction of infectious material which owes its infecting power to the presence of micro-organisms not containing spores, the Committee recommend:

1. Fire. Complete destruction by burning.
2. Boiling in water half an hour.
3. Dry heat. 110° C. (230° Fahr.) for two hours.
4. Chloride of lime.[1] 1 to 4 per cent. solution.
5. Solution of chlorinated soda.[2] 5 to 20 per cent. solution.
6. Mercuric chloride. A solution of 1 : 1000 to 1 : 4000.
7. Sulphur dioxide. Exposure for 12 hours to an atmosphere containing at least 4 volumes per cent. of this gas, preferably in presence of moisture.[3]
8. Carbolic acid. 2 to 5 per cent. solution.
9. Sulphate of copper. 2 to 5 per cent. solution.
10. Chloride of zinc. 4 to 10 per cent. solution.

The Committee would make the following recommendations with reference to the practical application of these agents for disinfecting purposes:

For Excreta.

(*a*) In the sick room:

For spore-containing material;

1. Chloride of lime in solution, 4 per cent.
2. Mercuric chloride in solution, 1 : to 500.[4]

In the absence of spores;

3. Carbolic acid in solution, 5 per cent.
4. Sulphate of copper in solution, 5 per cent.
5. Chloride of zinc in solution, 10 per cent.

(*b*) In privy vaults:

Mercuric chloride in solution, 1 : 500.[5]

(*c*) For the disinfection and deodorization of the surface of masses of organic material in privy vaults, etc.:

Chloride of lime in powder.[3]

For Clothing, Bedding, etc.

(*a*) Soiled underclothing, bed linen, etc.:

1. Destruction by fire, if of little value.
2. Boiling for at least half an hour.
3. Immersion in a solution of mercuric chloride of the strength of 1 : 2000 for four hours.[4]
4. Immersion in a 2 per cent. solution of carbolic acid for four hours.

(*b*) Outer garments of wool or silk, and similar articles, which would be injured by immersion in boiling water or in a disinfecting solution:

1. Exposure to dry heat at a temperature of 110° C. (230° F.) for two hours.
2. Fumigation with sulphurous acid gas for at least twelve hours, the clothing being freely exposed, and the gas present in the disinfection chamber in the proportion of four volumes per cent.

[1] This temperature does not destroy the spores of *B. subtilis* in the time mentioned, but is effective for the destruction of the spores of the anthrax bacillus and of all known pathogenic organisms.

[2] Should contain at least 25 per cent. of available chlorine.

[1] Should contain at least 3 per cent. of available chlorine.

[2] This will require the combustion of between three and four pounds of sulphur for every 1000 cubic feet of air space.

[3] The addition of an equal quantity of potassium permanganate as a deodorant, and to give color to the solution, is to be recommended (*Standard Solution No.* 2).

[4] A concentrated solution containing four ounces of mercuric chloride and one pound of cupric sulphate to the gallon of water, is recommended as *Standard Solution No.* 3. Eight ounces of this solution to the gallon of water will give a dilute solution for the disinfection of excreta, containing about 1 : 500 of mercuric chloride, and 1 : 125 of cupric sulphate.

[5] For this purpose the chloride of lime may be diluted with plaster of Paris, or with clean, well-dried sand, in the proportion of one part to nine.

[6] The blue solution containing sulphate of copper, diluted by adding two ounces of the concentrated solution to a gallon of water, may be used for this purpose.

Digitized by Google

(*c*) Mattresses and blankets soiled by the discharges of the sick.

1. Destruction by fire.
2. Exposure to superheated steam—25 pounds pressure—for one hour. (Mattresses to have the cover removed or freely opened.)
3. Immersion in boiling water for one hour.
4. Immersion in the blue solution (mercuric chloride and sulphate of copper), two fluidounces to the gallon of water.

For Furniture and Articles of Wood, Leather, and Porcelain.[1]

Washing, several times repeated, with:

1. Solution of mercuric chloride, 1 : 1000. (The blue solution, four ounces to the gallon of water, may be used.)
2. Solution of chloride of lime, 1 per cent.
3. Solution of carbolic acid, 2 per cent.

For the Person.

The hands and general surface of the body of attendants, of the sick, and of convalescents at the time of their discharge from hospital:

1. Solution of chlorinated soda diluted with nine parts of water (1 : 10).
2. Carbolic acid, 2 per cent. solution.
3. Mercuric chloride, 1 : 1000; recommended only for the hands, or for washing away infectious material from a limited area, not as a bath for the entire surface of the body.

For the Dead.

Envelop the body in a sheet thoroughly saturated with:

1. Chloride of lime in solution, 4 per cent.
2. Mercuric chloride in solution, 1 : 500.
3. Carbolic acid in solution, 5 per cent.

For the Sick Room and Hospital Wards.

(*a*) While occupied, wash all surfaces with:

1. Mercuric chloride in solution, 1 : 1000 (the blue solution containing sulphate of copper may be used).
2. Chloride of lime in solution, 1 per cent.
3. Carbolic acid in solution, 2 per cent.

(*b*) When vacated:

Fumigate with sulphur dioxide for 12 hours, burning 3 pounds of sulphur for every 1000 cubic feet of air space in the room; then wash all surfaces with one of the above-mentioned disinfecting solutions, and afterward with soap and hot water; finally throw open doors and windows and ventilate freely.

For Merchandise and the Mails.[2]

The disinfection of merchandise and of the mails will only be required under exceptional circumstances; free aëration will usually be sufficient. If disinfection seems necessary, fumigation with sulphur dioxide, as recommended for woollen clothing, etc., will be the only practicable method of accomplishing it.

For Rags.

(*a*) Rags which have been used for wiping away infectious discharges should at once be burned.

(*b*) Rags collected for papermakers during the prevalence of an epidemic should be disinfected before they are compressed in bales by:

1. Exposure to superheated steam (25 pounds pressure) for ten minutes.
2. Immersion in boiling water for half an hour.

(*c*) Rags in bales can only be disinfected by injecting superheated steam (50 pounds pressure) into the interior of the bale. The apparatus used must insure the penetration of the steam to every portion of the bale.

For Ships.

(*a*) Infected ships at sea should be washed in every accessible place, and especially the localities occupied by the sick, with:

1. Solution of mercuric chloride, 1 : 100 (the blue solution heretofore recommended may be used).
2. Solution of chloride of lime, 1 per cent.
3. Solution of carbolic acid, 2 per cent.

The bilge should be disinfected by the *liberal* use of a strong solution of mercuric chloride (the concentrated solution—"blue solution"—of this salt with cupric sulphate may be used).

(*b*) Upon arrival at a quarantine station an infected ship should at once be fumigated with sulphurous acid gas, using three pounds of sulphur to every 1000 cubic feet of air space; the cargo should then be discharged on lighters; a liberal supply of the concentrated solution of mercuric chloride (4 ounces to the gallon) should be thrown into the bilge, and at the end of twenty-four hours the bilge-water should be pumped out and replaced with *pure* sea-water; this should be repeated. A second fumigation after the removal of the cargo is to be recommended; all accessible surfaces should be washed with one of the disinfecting solutions heretofore recommended, and subsequently with soap and hot water.

[1] For articles of metal, use Solution No. 3.

[2] In order to secure penetration of the envelope by the sulphur dioxide, all mail matter should be perforated by a cutting stamp before fumigating.

HOSPITAL NOTES.

JEFFERSON MEDICAL COLLEGE HOSPITAL.

Service of PROF. S. W. GROSS, M.D.

THREE OVARIOTOMIES.

(Reported by M. P. Vander Horck, M.D., Resident Physician.)

THE following brief notes of three successful cases of ovariotomy, performed by a general surgeon in a general hospital, tend to show the absurdity of the position held by many specialists, namely, that such operations should only be undertaken by those who have been specially trained in this field of surgery, and who operate only in private houses or institutions.

CASE I.—A married woman, the mother of two children, was admitted September 14, having been tapped one month previously, and the enlargement of the belly having existed for four years and a half. Two days subsequently, a median incision, two inches long, was made midway between the umbilicus and the

Digitized by Google

pubes; slight adhesions were broken up; a catgut ligature was applied to a bleeding vessel of the slightly adherent omentum; the contents of the cyst—two gallons of fluid—were evacuated; and the pedicle tied with a violincello string, and dropped. The external wound was closed with four silver sutures, which included the entire thickness of the abdominal wall, and the usual dressings applied. The operation was conducted under strict antiseptic precautions, including the spray, carbolic acid being the agent used. The stitches were removed on the tenth day; the patient was permitted to walk about the room on the fifteenth day, and was discharged five days subsequently.

CASE II.—A virgin, aged twenty-two, was admitted January 31, having been tapped three months previously, and the symptoms having existed for eight months. As in the first case, a short incision was made; slight adhesions were broken up; and two gallons of fluid evacuated from the multilocular cyst. The pedicle was tied with the same material and dropped, and the wound closed with three silver sutures. The spray and other antiseptic precautions were employed during the operation; the wires were removed on the eleventh day, and the patient went home seven days later.

CASE III.—A primipara aged thirty, who had had symptoms of ovarian cyst for two years and a half, was admitted October 17, and the cyst, which, with its contents, weighed eighteen pounds, was removed two days subsequently. There were no adhesions; the pedicle was tied with a violincello string and dropped, and the external wound closed with five silver sutures. In this case the spray was omitted, and a 1 to 1000 solution of corrosive chloride used for the hands, ligature, and outer dressings. The stitches were removed on the eleventh day; the patient sat up on the fourteenth day, and was discharged four days subsequently.

Remarks.—The highest temperature observed in any of these cases was 100⅛° F., and the convalescence in all was not interrupted by any untoward occurrence. In all, the pedicle was transfixed by a probe carrying a double catgut ligature, and tied in two portions before the cyst was detached. The preliminary preparations consisted in the administration of ten grains of calomel two nights before the operation, to clear out the bowels, and the exhibition of at least thirty grains of quinine, in ten grain doses, to obviate shock. Food was withheld for twenty-four hours after the operation, when a small quantity of milk was allowed, which was gradually increased, and alternated with soups. Solid food was not permitted for eight or ten days. As soon as the patient began to feel uncomfortable in the intestinal tract, which usually happened about the eighth day, six ounces of olive oil were thrown into the rectum, and half a ounce of castor oil administered by the mouth. With this exception, medication was not called for.

MEDICAL PROGRESS.

ANTISEPSIS IN OBSTETRICS.—In a recent monograph by C. FÜRST (*Die Antisepsis bei Schwangeren, Gebärenden u. Wöcherinnen*, Wien, 1885), the following conclusions are offered regarding injections of corrosive sublimate:

1. Large quantities of strong solutions must be avoided; the prolonged action of such solutions, or the continuous irrigation of fresh wounds therewith being dangerous. The fluid used must be expelled as far as possible. Before such irrigation, the uterus should be first lifted, and then compressed (Fritsch). Subsequent injection with some other antiseptic solution is recommended (Tänzer).

2. Anæmia enhances the danger attending the use of both carbolic acid and corrosive sublimate.

3. Diminished renal activity constitutes a contraindication for the use of such injections; and the state of the kidney in pregnancy probably conditions a marked predisposition to sublimate poisoning.

4. Especial caution is advised in high fever and septic diarrhœa.

5. The exit of the sublimate solution from the uterus through the Fallopian tube is especially dangerous.—*Centralb. f. Gynäk.*, Nov. 14, 1885.

EXCISION OF A CHANCRE.—The following interesting and apparently conclusive piece of evidence bearing upon the utility of the extirpation of the initial sore, is quoted from LENOIR'S lectures on syphilis.

A student in 1882 told him that on the previous night he had had intercourse with a woman who, he subsequently found out, was syphilitic. The woman had eroded papules of the vulva. The student was told to watch closely for the least appearance of a symptom, and to pay particular attention to any ganglionic engorgement or induration. He used a magnifying glass, and upon going to bed and arising in the morning he carefully examined his genitals with a good lens. He became a monomaniac upon the subject. Upon the 22d day at 2 o'clock in the afternoon he burst into Lenoir's office and, and having already come twice that day without seeing him, the first thing he did was to show his penis. Upon the free edge of the prepuce an elevated erosion was situated, as large as the head of a pin. It was rather a macule than an erosion; no trace of any induration, no inguinal adenopathy. This sore had appeared since midnight and it was only in the morning that the patient had observed it. The rest of the patient's integument was examined but absolutely nothing found. Supposing that this small erosion might be a chancre it was excised, a portion as large as a dime being removed. Cicatrization repidly followed without any induration taking place. But a few days later the inguinal ganglia became engorged and about six weeks later the secondary symptoms burst out as roseola, alopecia, and eroded papules. It certainly was not fourteen hours after its appearance that thorough excision was made, and yet the sequel proved how futile the means was. It would be well if many of the advocates of the local nature of syphilis at its inception were to take this example and ponder over it.—*St. Louis Med. and Surg. Journal*, October, 1885.

EXPERIMENTS UPON THE GASTRIC DIGESTION OF MILK.—The following results were obtained by REICHMANN in a series of observations upon the length of time required for the digestion of milk in the healthy human stomach. About one-half pint of raw milk was usually given to the person under observation, and removed by the sound and pump at varying intervals of time. The quantity mentioned was found to be digested in three

Digitized by Google

hours, and in four hours the last traces of acid fluid had left the stomach. The maximum gastric acidity (0.32 per cent.) was attained in one hour and fifteen minutes. Peptone appeared in noteworthy amount in from thirty minutes to two hours. Boiled milk was found to be somewhat more rapidly digested than was raw milk.—*Zeitschr. f. klin. Med.*, Bd. ix. Hft. vi., 1885, p. 565.

MULTIPLE ULCERATIONS OF THE DIGESTIVE TRACT PRODUCED BY LARGE DOSES OF MORPHIA.—A. SOURROUILLE reports the exhibition, in a case of uterine carcinoma, of morphia in doses increasing from three-fourths of a grain to four grains. The sedative effect was prompt, but untoward effects soon appeared: thirst, dryness of mouth and œsophagus, with dysphagia, anorexia, constipation, etc. On the mucous membrane of the mouth and pharynx, and probably also at other points in the digestive canal, appeared a series of sharply outlined ulcerations of varying depth which rendered alimentation impossible. The symptoms disappeared upon the withdrawal of the drug, to reappear upon its renewal. Sourrouille maintains that morphia induces atrophy of the secretory organs and destroys the epithelium with which it comes in contact.—*Centralb. f. d. med. Wissensch.*, Nov. 7, 1885.

NEPHROTOMY FOR TOTAL SUPPRESSION OF URINE.—The patient upon whom Mr. Clement Lucas operated for total suppression of urine, lasting four days and six hours, and whose case was described in THE MEDICAL NEWS of November 21, 1885, is progressing favorably and gradually gaining strength. As, during the first week, no urine reached the bladder, a little concern was felt lest there might be another stone impacted in some lower part of the ureter. All anxiety on this score was, however, dispelled on the twelfth day, when, for the first time, the patient voided about two ounces and a half of urine by the urethra. Since that time, the amount passed *per vias naturales* has gradually increased. The wound has healed primarily, except where the drainage-tube is inserted, and the patient's temperature has scarcely risen above normal since the operation.

Mr. Lucas's case of nephrectomy, performed on October 20th, left the hospital well just three weeks from the date of the operation.—*British Medical Journal*, November 21, 1885.

ANTIPYRETIC ACTION OF THALLIN.—At the suggestion of von Jacksch, JACCOUD has administered thallin in eleven febrile cases, chiefly typhoid and tubercular. The sulphate and the tartrate of thallin were used with equally marked results; the average daily dose was eight grains, with a maximum of fifteen grains and a minimum of one and a half grains. The thallin salt was given in divided doses of two and a quarter to three grains at intervals of fifteen to thirty minutes.

The effect of the drug thus administered was constant, the average fall of temperature being 4.05° F. One patient, who received fifteen grains of the salt in the course of two hours, was threatened with collapse, the temperature falling 10.08° F. Jaccoud, therefore, states that great care must be exercised in avoiding the exhibition of an excess of the drug, and considers three-quarters to one and a half grains per hour, until the desired result is attained, as probably the correct dose. —*Gaz. des Hôpitaux*, 1885, No. 73.

GRAFT OF FROG'S SKIN UPON HUMAN NECK.—M. PETERSON has repeated his previous experiments relative to the grafting of frog's skin. The patient in this case suffered from an ulcer of the neck, and refused to furnish the flakes of skin needed for the grafting. Six graftings of frog's skin were required, several flakes being employed upon each occasion. The patient was discharged, as cured, forty-two days from the beginning of the treatment.—*Gaz. Hebd. de Méd. et de Chir.*, Nov. 13, 1885.

HYDROPNEUMOPERICARDIUM PRODUCED BY ROUND ULCER OF THE STOMACH.—DR. PARISOT, of Nancy, has collected (*Revue Médicale de l'Est.*, Oct. 1, 1885) six cases of this grave complication of gastric ulcer. The disease in each case was fatal, the termination being either cardiac paralysis or asphyxia. Out of 14 cases of pneumopericardium, from divers causes, only 4 ended in recovery. When the diagnosis of hydropneumopericardium is once made, the diagnosis of its origin from round gastric ulcer is based upon the following points:

1. Dyspeptic symptoms, hæmatemesis, etc.
2. Percussion: same pitch of sound in epigastric and præcordial regions.
3. Auscultation: transmission of abnormal bruits from præcordial region across the intestinal mass.
4. Functional derangements: general discomfort, and augmentation of dyspnœa by the presence in the stomach of volatile liquids (*e.g.*, ether).

Treatment. Prophylaxis.—The sufferer from round gastric ulcer must avoid all exertion, in order that the chance of rupture of the ulcer into the pericardium may be diminished. Cough and vomiting are for the same reason to be combated.

The communication between the pericardium and stomach once established, nothing remains but palliative treatment; nutritive enemata are, of course, in order, and the amount of fluid permitted to enter the stomach at one time should be very small. All medicinal agents (morphia, ether) should be exhibited only by the hypodermic method.—*Rev. de Thérap.*, Nov. 1, 1885.

INJECTION OF ESSENCE OF TURPENTINE IN FISTULÆ. —M. SETT. CECCHINI (*Annali univ. di Med.*, 1885, p. 101) claims for the injection of turpentine in fistulæ an alterative, a cicatricial, and, above all, an antiseptic action, in which last regard he considers the drug to be superior to carbolic and salicylic acids, thymol, and even the salts of mercury. It is injected either pure or diluted with olive or almond oil. The action is better and more rapid if the undiluted essence is used. With timid patients the essence of turpentine is mixed with a solution of chloride of morphia, with a reduction to a minimum of the pain involved. The method has been employed by Cecchini with success in five out of seven cases of anal fistula; without failure in six cases of caries of the petrous bone, and in eight cases of dental fistula complicated by a greater or less degree of caries of the maxilla. This treatment failed in one case of fistula of

Digitized by Google

Steno's duct, and was completely successful in fifteen cases of atonic fistula.—*Gaz. Hebd. de Méd. et de Chir.*, Nov. 13, 1885.

COCAINE IN THE TREATMENT OF VAGINISMUS.—According to J. SCHRANK (*Wien. med. Wochenschr.*, 1885, No. 38) vaginismus may be regarded as the analogue of anal fissure, both in its symptoms and in its mode of causation. The condition is usually associated with a narrow vagina and tough hymen, the rupture of which latter, during introitus vaginæ, extends further than is needful. After producing local anæsthesia by the application of a four per cent. solution of cocaine, he dilates the vagina with a rectal speculum, thereby preventing cicatricial contraction of the lacerated parts, —with resultant disappearance of the vaginismus.—*Deutsche med. Wochenschr.*, 1885, No. 43.

THE PRESENCE OF PEPTONE IN INCUBATED HEN'S EGGS AND IN FIBROMATA OF THE UTERUS.—The earlier observations of FISCHEL (*Arch. f. Gynäk.*, Bd. 24 S. 425, 1884), in which he found peptonuria to be a frequent concomitant of pregnancy, and constantly present in the puerperal state, have led to further interesting experiments. In the course of 1884–85, forty-two hen's eggs, in various stages of incubation, have been carefully examined for peptone by the biuret reaction, with polarimetric confirmation, by Huppert's method. Peptone was absent until the fifteenth day of incubation, but usually present thereafter. Fischel is apparently unacquainted with the observations of Reichert, of Philadelphia, who has demonstrated the presence of peptone in the unincubated egg (*Phila. Med. Times*, May 17, 1884).

Fischel has further twice investigated uterine fibromyomata, and has shown the presence of peptone therein in both instances. The peptone in question appertained to the tissues of the tumor, inasmuch as in the contents of the abundant lymph and bloodvessels the peptone reaction was absent.—*Zeitschr. f. physiol. Chem.*, November 2, 1885.

PAROTITIS AFTER OVARIOTOMY.—The well-known connection existing between the parotid gland and the genital apparatus, frequently manifested in a swelling of the testis subsequent to parotid inflammation, has recently been found to express itself when the reproductive gland constitutes the initial point of irritation. Thus in addition to the case of Billroth, in which parotitis followed a traumatic orchitis, there are now on record nine cases in which inflammation of the parotid appeared as a sequel of ovariotomy. Five of these cases are described by Möricke (*Centralb. f. Chir.*, 1880, p. 667); two by Macdonald (*Edinb. Med. Journ.*, July, 1885); and two by Matwêff (*Ann. de Gynèc.*, xxiv. p. 105). In only one of these cases did any possibility of infection exist.—*Centralb. f. Chirurgie*, November 14, 1885.

MERCURIAL SOAP.—DR. SCHUSTER, of Aix, describes a mercurial soap, infrictions of which induce distinct swelling of the gums and increased salivary secretion after from five to twelve applications of ten to fifteen minutes' duration.

The composition of the soap, as made for Schuster by a local apothecary, is as follows:

Lard	400 parts.
Liq. kali. caust. (sp. gr. 1.33) . .	200 "
Saponify *lege artis*, and add water	100 "

Four hundred grammes of mercury are then most carefully rubbed up in two hundred grammes of tallow, with the addition of a little chloroform, which favors the subdivision of the mercury, and slowly, but completely, evaporates. Six hundred grammes of the potash soap, as above prepared, are slowly added and thoroughly mixed.—*Monatshefte f. prakt. Dermatologie*, November, 1885.

PROPHYLAXIS OF GONORRHŒA.—After passing in review the various hygienic prbcedures designed to diminish the liability to gonorrhœal infection, M. MARTINEAU strongly recommends the use of warm solution of bichloride of mercury, one part in five hundred, as a wash and injection. "It is desirable," he adds, "that every prostitute should have this solution in her room for the use of both parties before and after coition. The application of this solution to the surfaces exposed to contagion is without danger, and is very efficacious in its action upon the gonococcus." The formula given is as follows:

℞.—Corrosive sublimate . . .	2 parts.
Ammonium chloride . . .	6 "
Alcohol	200 "
Water . . . q. s. ad.	1000 "

—*Rev. de Thérap.*, Nov. 15, 1885.

SUICIDAL ATTEMPT WITH PETROLEUM.—REIHLEN (*Aerztl. Intelligenzbl.*, 1885, No. 35) reports the case of a vigorous female servant, twenty-two years of age, brought, unconscious, into the hospital. No response to auditory stimuli, and but feeble reflex movements when pricked with a needle. General appearance that of one in deep sleep; pupils reacted promptly; pulse, respiration, and temperature normal. No appreciable alteration in viscera. Odor of petroleum very marked, though a few drops only could be obtained on siphon out of the stomach. It was learned that the patient had, without vomiting, drunk five fluidounces of ordinary pure petroleum.

In the course of the afternoon patient urinated, and in the evening she recovered consciousness. On the following day she was greatly exhausted and very dull, but on the third day was completely recovered. The urine of the first day was apparently normal. A sample obtained by the introduction of an unoiled catheter, forty-eight hours after the attempt, possessed a strong oily odor, and showed a few large oily drops upon its surface, which analysis showed to consist of petroleum. No albumen or morphological constituents were at any time found in the urine. The odor of petroleum in the breath disappeared after five days.

Cases of poisoning with petroleum are rare and almost always progress favorably.

Merkel relates the case of a man who drank habitually an ordinary liquorglass of petroleum several times weekly without any disagreeable consequences.—*Deutsche med. Wochenschr.*, 1885, No. 43.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, DECEMBER 12, 1885.

THE FUTURE OF THE CONGRESS.

IT is generally conceded that the miscarriage of the plans for the organization of the proposed International Medical Congress at Washington has inflicted an injury upon the profession of this country which is widespread, and cannot yet be fully estimated, and a latent hope has been largely indulged in that some plan might still be devised by which all differences could be healed, the profession harmonized, and its good name rescued from imminent disgrace.

The time which should have been spent in active preparation for the great International gathering is now half gone, and to-day we have to show as the net result of the work yet done—discredit abroad, apparently hopeless dissension stirred up at home, and no actual preparation for the meeting. But eighteen months still remain, and we are so hopeful as to believe that even in that short time it is yet possible in a great measure to wipe out the injury done, to restore largely our good name abroad, to reunite our profession at home, and to make such preparations as will result in a creditable meeting of the Congress in our National Capital; but to effect this, immediate, concerted, and Herculean efforts, together with extensive mutual concessions, must be made—a delay of ninety days will make the difference between positive failure and possible success.

It is useless to consider the causes which have produced the existing lamentable condition of affairs; each side has its own explanation, but the fact remains. The time has now arrived when honor rises superior to all other interests, and demands that we shall combine for international purposes, and make good the invitation which, in the name of the medical profession of this country, was extended to our brethren of foreign lands to hold their next Congress at Washington.

Everyone who has had the true honor of his profession at heart, regardless of the mistakes that he thinks others have made, has looked upon the situation with feelings of the deepest sorrow and mortification, and has felt that, under the circumstances, any honorable sacrifice to avert the threatened disaster was a duty he owed to his profession and to his country. In this feeling the profession of Philadelphia share. Their city was the birthplace of the American Medical Association, and gave her the Code of Ethics. She is as thoroughly loyal to the Association and the Code now as she was thirty-eight years ago. Actuated by the same motives which influenced her then and made her a potent factor in the councils of the national profession, Philadelphia, after mature deliberation, exerts her influence again to-day for harmony, for concert of action, for the re-establishment of the good name of the profession, for the integrity of the American Medical Association. As she lately felt impelled by duty to set her face against the disastrous influences which were warmed into life at the New Orleans meeting, and are tending to the disintegration of the Association, and, as her voice went not unheeded, she now is emboldened to speak again, to the end that a practicable solution of our difficulties be enforced, so that our pledges to our foreign brethren may be redeemed, and our honor not become throughout foreign lands a byword and a reproach. Such a solution must be formed on a basis sufficiently broad to harmonize the *whole* profession; and, probably, the only practicable way of reaching it now would be, as the profession of Philadelphia have formally pointed out, by a union of the present Executive Committee with the Original Enlarged General Committee, and by this joint body beginning the work of preliminary organization *de novo*. Nothing less than this will meet the exigencies of the case.

We cannot but hope that the few who now have it in their power to effect this harmony will use their influence to that end, and by their action, under the present trying circumstances, show that they are ready to sink personal considerations for the public good. The occasion is one for the display of the highest patriotism, and the end to be attained is worthy of the greatest sacrifices. In accordance with the motto of one of the oldest medical societies of our country, let them act, *non sibi sed toti*.

TREATMENT OF ANEURISM OF THE ABDOMINAL AORTA.

THE medical treatment of aneurism of the aorta, consisting chiefly in absolute rest, starvation, and the administration of the iodide of potassium or of ergot,

Digitized by Google

or of digitalis, has effected cures in a certain number of cases. Yet there will always be many which are not amenable to these methods, and which will require some surgical interference unless the patient is to be abandoned wholly to his fate.

The conventional treatment for other aneurisms, namely, ligation, is perhaps quite inapplicable to aneurisms of the aorta. For those of its abdominal part the operation has never been done. It is true that this part of the aorta has been ligated not less than ten times, but eight of these operations were done as near the iliac bifurcation as possible, for aneurisms involving the vessels below; while once the aorta was tied by mistake for the iliac, and once it was tied because it was impossible otherwise to control hemorrhage from the renal artery after extirpation of the kidney. Of the patients, none lived more than a few hours, except one, operated upon by Monteiro, who survived ten days and died of hemorrhage from an opening in the aorta above the ligature, and one of Patrick Heron Watson, who lived seven days and died of gangrene of the legs. References to all of these operations are given in the sixth edition of Gross's *Surgery*, and full and accurate details of them are to be found in a recent paper by P. LIEBRECHT, of Liége (reprint from *Journal d'Accouchements et Révue de Méd. et de Chir. pratiques*, Sept., Oct., and Nov., 1885), which contains a translation of, and comments upon, a report of an operation for the cure of an abdominal aneurism, high up on the aorta, by Loreta, of Bologna.

In this case Loreta, after a careful study of its peculiarities and of the results of other operative procedures in analogous cases, decided to open the abdomen, and to introduce into the sac of the aneurism a metal wire. This he did, using a silvered copper wire, half a millimetre in thickness, which he passed through a fine canula, piloted by a trocar and thrust into the aneurism. When he had introduced more than two yards of the wire, he pushed the end of it into the sac, and withdrew the canula. He now touched the point of puncture with carbolic acid, and had not a drop of bleeding. The further details of the operation consisted in replacing the viscera: the colon, stomach, and omentum, and in closing the wall of the abdomen with nine interrupted sutures. The wound healed by first intention, and the patient's condition was at once improved. The tumor, which had been as large as the head of a newborn child, diminished to the size of a walnut by the seventieth day after the operation, when the aneurism was considered to be cured. On the ninety-second day after the operation the patient died of rupture of the aorta below the sac. An autopsy disclosed the fact that the aneurism was filled with consolidated fibrinous clots, and was of the smallness mentioned. The rupture of the aorta below the sac was attributed by Loreta to an ischæmia of the tunics of the aorta, due to compression and to changes going on in the interior of the sac. Besides this, the patient was believed to be syphilitic.

It is to be noted as a defect in the report of this case, that the account of the autopsy does not settle distinctly the exact seat and relations of the aneurismal sac, or the causes of some of the symptoms observed before the operation.

But we have here a noteworthy contribution to the methods of treating aneurism within the abdominal cavity. The operation may be considered, we think, a practical success, and to invite imitation. The operator acknowledges his indebtedness to the practice of Moore of London, who, in 1864, introduced twenty-six yards of fine wire into an aneurism of the ascending aorta, but whose patient died in a few days. The practice of Levis, of Philadelphia, who first introduced horsehair into an aneurism, was not imitated by Loreta, because he feared septicæmia. If he had been familiar with the innocence of disinfected horsehair, used as a drain, we think he would not have objected to it on the ground mentioned. Indeed, we believe that such disinfected horsehair may yet prove to be the best foreign substance to introduce into an aneurism; for we cannot avoid the suspicion that the fatal termination of Loreta's case may have been caused by mechanical irritation of the wall of the aorta due to the rigidity of the material he used.

In deciding upon an operation for the cure of an aneurism of the abdominal aorta, it would not be right to overlook the comparatively good results which have followed the employment of mechanical compression, as by Lister's compressor. Of twelve cases treated in this way, five—one of which seems almost incredible—have recovered, two are set down as failures, and five died soon afterward of peritonitis, gangrene of the intestine, or rupture of the sac.

Finally, we would call attention to a suggestion made by Liebrecht, in the paper before us, that a method similar to that so successfully employed by Loreta might be combined with partial occlusion of the lumen of the aorta by a ligature which should not obliterate it entirely. This might prove a valuable modification of the operation by introducing wire or horsehair, which, before the case we have been discussing had appeared, has been adjudged by some of the most eminent surgical authorities to be utterly useless. One swallow does not make a summer; but we believe one success like that of Loreta warrants a reconsideration of this opinion.

UTERINE HÆMOSTATICS.

UTERINE hemorrhage is so frequent an accident, and in so many cases has such serious consequences, immediate or remote, that means for its arrest have

Digitized by Google

been eagerly sought. Medicines that have been, or are used as uterine hæmostatics, may be counted by the score, but he who should try these various means would probably, at the end of his experience, be in the condition of Sganarelle, in one of Molière's plays, who said, "Remember never to believe anything, even if you should see everything." Some one has said that the end of all philosophy is a learned doubt, and certainly the end of all investigations as to the value of the many medicines asserted to be uterine hæmostatics will be a learned doubt, if not a positive denial of such virtue to the majority of these, and a qualified approval of the few remaining. Indeed, we know a distinguished gynecologist who rejects this entire class of agents; he has been so often disappointed by individual members of it, and relies solely upon copious vaginal injections of hot water.

Probably the tendency of therapeutics in recent years is to rely less upon the gross elements of materia medica, the things which we can see, handle, weigh, and more upon the subtle forces, such as heat and electricity, which the physician can bring to his command. And this tendency is very clearly shown in the department of obstetrics and diseases of women. The astringents, mineral or vegetable, which were once in such vogue, are now rarely employed for the cure of uterine hemorrhage; if the hemorrhage be grave and the danger imminent, one hardly feels like trusting a medicine which must first enter the circulation and then, in almost infinitesimal dilution, travel to the bleeding part, having there slight or doubtful therapeutic influence, when, by either of the forces mentioned, an instant and positive effect can be produced in most cases. Contraction of bloodvessels, or of the musculature of the uterus, or of both, must be the ultimate styptic power. The sooner that contraction is evoked, therefore, the better. A foreign body, as from incomplete abortion, or as in retention of the placenta in labor at term, may prevent perfect uterine contraction, and, therefore, this foreign body must be removed before a permanent cure is effected.

We may, by certain remedies, such as digitalis, slow the circulation, and thus lessen the flow, but we do not thereby cure. When hemorrhage results from an altered condition of the blood so that it has lost its plasticity, and thus one hemorrhage invites another, deep calling unto deep, we may in some of the cases ultimately cure the flow by remedies which improve the condition of the blood, a process, however, which requires weeks for its accomplishment. When the hemorrhage is consequent upon a toxæmia, as malarial poisoning, medicines addressed directly to that state, such as quinine or arsenic, in most cases prove of marked value.

The tincture of Indian-hemp has been strongly recommended in the hemorrhage caused by uterine fibroids, and in menorrhagia associated with painful menstruation: it is an uncertain remedy, and when it does do good, probably it is solely from the relief of the pain which acts in causing an increased afflux of blood to the uterus. So too opium may, in like manner, act favorably in similar cases, yet neither of these remedies is to be regarded as a certain uterine hæmostatic. The alkaline bromides, from their sedative influence upon the ovaries, may have a beneficial influence in some cases of menorrhagia.

A few months ago a distinguished German authority reported very favorable results from the tincture of hydrastin. The use of this agent for the relief of uterine hemorrhage is not new, at least in this country, but we cannot say from our own experience with the drug, which is probably too limited to justify a positive opinion, that its beneficial action is observed in all cases, or even in the majority. Kugelmann, however, has recently stated that he had succeeded in causing the menopause by hydrastin administered internally, and the local application of iodine.

Hamamelis has received the strong endorsement of CHÉRON in the October number of the *Révue Médico-Chirurgicale des Maladies des Femmes*. He advises fifteen to sixty drops of a tincture made of equal parts by weight of hamamelis and alcohol, twice a day. He also uses the solid extract, one part to five of glycerine, as an application to the neck of the womb, or the extract with cocoa butter, as a vaginal suppository. He asserts that this medicine exerts a positive influence upon hemorrhages and passive congestions, and upon the pain which accompanies these morbid states.

Ergot probably ranks in the professional mind at the head of uterine hæmostatics. It certainly is one of the most valuable remedies both for the obstetrician and the gynecologist. Without considering the obstetric uses of this agent, we may remark that its value in controlling uterine hemorrhage bears a direct relation to the development of the uterus; if this organ be of normal size in the unimpregnated condition, the power of ergot is usually slight, whereas if it be much enlarged, as by a fibroid tumor, that condition termed fibrous pregnancy existing, more decided effects from the remedy may be justly expected. We believe, in all cases of uterine hemorrhage, whether consequent upon a fibroid or not, and when the medicine is continued for a length of time, iron can be usefully combined with it, though there has been a vague notion that iron increases the flow, and, hence, is not to be administered when this is excessive. But, in the ergot treatment of uterine fibroids, it frequently happens that a good result is not obtained until the medicine is administered hypodermically. Why this should be so does not seem clear; that it is so some excellent professional observers

Digitized by Google

assert. In hemorrhage from cancer ergot is useless; and this statement is true, whether the hemorrhage be caused by active congestion as it is in the early stage of the disease, or whether it result from ulceration, as it does in the further progress of the malady.

Time permits a reference to only one other uterine hæmostatic, to wit, hot water. This is applied by means of a rubber bag to the lumbar vertebra, or by vaginal injections. For the vaginal use of hot water to lessen profuse menstruation the profession is indebted to Trousseau, though its general use in uterine hemorrhage must be credited to Emmet. Vaginal injections of very hot water constitute one of the most certain means for the arrest of uterine hemorrhage; in some cases the injection is carried into the uterus. Those who have frequently failed with this means certainly have not used the water hot enough, or in sufficient quantity, or with the patient in proper position.

In regard to the mode of action of heat thus applied, all are agreed that it produces contraction of bloodvessels; though some, as Kleinwächter, insist that dilatation soon returns. Be this as it may, we have always regarded one of the asserted proofs of contraction of bloodvessels thus affected as possibly an erroneous interpretation of a fact. The shrivelled, shrunken skin of the fingers of a washerwoman, after having her hands in "the suds" for a time, is appealed to as a proof of the contractile power exerted by hot water. But the condition may be dependent upon osmosis from the vessels of the hand, rather than upon muscular contraction of bloodvessels. Those vessels are relatively emptied, not by compression, or at least not solely by it, but by the pressing out of a portion of their contents.

A NEW HYPNOTIC.

A MIXED acetone, known as phenyl-methyl acetone, the actions of which have been studied by Popof, of Warsaw, has been found by Dujardin-Beaumetz and Bardet, to possess valuable hypnotic properties. Within the body it is transformed into carbonic and benzoic acids, and is finally eliminated in the urine as hippurates. A dose of from 5 to 15 centigrammes, mixed with a little glycerine, and given in a gelatine capsule, causes in an adult a profound sleep. In alcoholic insomnia it seems to act better than chloral or paraldehyde, and in nine cases no ill effects were observed. The odor of the breath is rendered unpleasant by the elimination of acetone from the lungs. Injected beneath the skin of a guinea-pig it produces a remarkable torpor, which gradually deepens into coma, and the animal dies in five or six hours.

The name *hypnone* is suggested as a more suitable designation for this acetone.

REVIEWS.

AN ATLAS OF CLINICAL MICROSCOPY. By ALEXANDER PEYER, M.D. Translated and Edited by ALFRED C. GIRARD, M.D., Assistant Surgeon, U. S. Army. Ninety plates, with 105 illustrations. New York: Appleton & Co., 1885.

IN glancing over the original, *Microscopie am Krankenbette*, there was something about the work which we did not like, a flavor which did not commend itself to our mental palate. This seems a little less apparent on a careful inspection of the translation; though it remains very evident that the work is not one of a master. Dr. Peyer is a practitioner at Schaffhausen on the Rhine, who, after five years' practice, revisited the University in order to fill certain gaps in his knowledge. Clinical microscopy engaged a large share of his attention, and at the suggestion of a friend he began to draw systematically the various microscopic preparations he met with in practice. In the course of a few years, he thus accumulated a large number of drawings, and this *Atlas* is the result. The plates are generally good—better, on the whole, than the text. There are, however, some exceptions; the figures of anthrax bacilli in the blood do not represent these bodies. Either Dr. Peyer is a poor artist, which the excellence of the other drawings shows is not the case, or the specimen was one of vibriones. In the text, too, he speaks of the organism as "*a globular* or rod-shaped bacterium!" Neither the plates nor the description of the epithelium from the genito-urinary passages are reliable; the author has evidently never made a careful study of the epithelium of these parts in health. Eleven of the ninety plates illustrate spermatorrhœa, four or five of which are quite superfluous. Far too great stress is laid upon this condition, and not a word is said of the fact that a slight loss of semen at times with the urine may be considered normal in many men. The microscopy of the stools, which is stated to be the one least cultivated by the practitioner, has not sufficiently engaged Dr. Peyer's attention, or we should have had more than a single plate illustrating this important subject. We regret that we cannot recommend Dr. Peyer as a safe guide to the practitioner; the more so as the profession is just now in need of a good work on clinical microscopy. It is to be hoped that the translation of Bizzozero's *Manual*, which has been announced, will soon appear, as it will supply wants which this work scarcely meets. The author of this *Atlas* must not be confounded with the learned Professor of Physiology at Jena, W. Preyer—a mistake which we have heard made.

The translation seems very good; the plates are beautifully executed, and the work has the excellent finish which characterizes Appleton & Co.'s medical publications.

THE MEDICAL NEWS VISITING LIST, 1886. Philadelphia: Lea Brothers & Co., 1885.

THIS is not simply a visiting list, but will be a true *vade mecum* for the busy practitioner, who will find in the first fifty pages an astonishing amount of valuable information in a condensed form. The therapeutic section covers nearly twenty pages and contains a valuable

Digitized by Google

table arranged from Lauder Brunton's text-book. A section on the ligation of arteries seems out of place in a visiting list, but a surgical emergency may arise when the practitioner is far from books and assistance, and just such a short account as is here given may refresh his memory and give steadiness to his hand. It appears in a firm, substantial dress, needful for a book so constantly in use.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 3, 1885.

THE PRESIDENT, A. JACOBI, M.D., IN THE CHAIR.

NOMINATIONS FOR OFFICERS.

THE following nominations were made:

Vice-President: Drs. Henry D. Noyes and Wm. H. Draper.

Recording Secretary: Drs. Arthur M. Jacobus, George L. Peabody, and Frank P. Foster.

Corresponding Secretary: Drs. A. R. Robinson, H. J. Garrigues, and Wesley M. Carpenter.

Treasurer: Drs. Wm. H. Cushman, Joseph D. Bryant, and D. B. St. John Roosa.

Committee on Admissions: Drs. J. H. Emerson and Laurence Johnson.

Committee on Ethics: Drs. S. O. Vanderpoel, Joseph D. Bryant, and A. B. Judson.

Committee on Medical Education: Drs. D. B. St. John Roosa, David Webster, and C. Heitzmann.

Committee on Library: Drs. C. H. Katzenbach, J. A. Andrews, Laurence Johnson, R. H. Amidon, and Chas. T. Poore.

Trustees: Drs. George A. Peters and James H. Anderson.

THE WILLARD PARKER HOSPITAL.

The Secretary read a communication from Dr. E. H. James, Assistant Sanitary Superintendent of the Board of Health, announcing that the new Willard Parker Hospital, in East 16th Street, is now open for the reception and treatment of cases of contagious disease, and invited the President and Fellows of the Academy to visit it and inspect its accommodations. It is provided with a resident physician and a corps of trained nurses, and is designed for the treatment of patients suffering from such diseases as scarlet fever and diphtheria, who cannot receive proper care in their own homes.

DR. MORRIS H. HENRY read a

REVIEW OF THE LIFE OF THE LATE DR. LOUIS ELSBERG, AND OF THE ADVANCEMENT OF OUR KNOWLEDGE OF DISEASES OF THE THROAT DURING HIS PROFESSIONAL CAREER.

He paid a tribute to the memory of the late Dr. Horace Green, who died twenty years ago. As Dr. Elsberg was the first in this country to teach the use of the laryngoscope and to hold a public laryngological clinic, so Dr. Green was the first teacher of medicine who paid special attention to diseases of the throat.

DR. SAMUEL W. SMITH read a paper entitled

ORIGINAL DEDUCTIONS BASED ON A STUDY OF ONE HUNDRED CASES OF FRACTURE OF THE UPPER EXTREMITIES, EXCLUDING THE HAND.

He stated that he claimed no originality in what he had to say, except in regard to the use of certain splints devised by himself, which, so far as he was aware, had not before been employed. Nearly half of the hundred cases had been in children under twelve years of age. Of those occurring in children under twelve, twenty-five were fractures of the clavicle; while in patients between the ages of twelve and fifty, only eight had been fractures of the clavicle. Having spoken of the character of fractures of the clavicle observed by him, the deformity in which he attributed in large measure to the action of the subclavius muscle, he went on to treat of fractures of the humerus, in describing which, he mentioned that he referred particularly to those of the lower end of the humerus, where the fracture was through one or both condyles or caused a separation of the epiphysis. In speaking of fractures of the radius he paid special attention to the so-called cases of Colles's fractures, and referred to the character of the obliquity that is met with in different cases. The kind of apparatus required in any case, he said, depends on whether the obliquity is long or short. He denominates fractures of the lower end of the radius Colles's fracture only when they are of the long oblique variety. When the fracture is transverse, or of short obliquity, the deformity is easily reduced and the fragments readily retained in position.

In the treatment of fractures of the clavicle, of course, a great variety of apparatus has been devised, but those most commonly in use are Desault's method, with the axillary pad, Levis's modification of Fox's treatment, Sayre's adhesive plaster dressing, and E. M. Moore's shawl or figure-of-eight bandage. Sayre's method is simple and generally efficient, but a great objection to it is the irritation of the skin which the plaster is liable to produce, especially in young subjects. The compression of the forearm across the chest also interferes more or less with the circulation, and may cause so much discomfort as to call for its removal. Consequently, Dr. Moore's dressing is a step in advance; but neither the Moore or Sayre method is efficient when the seat of the fracture is located near the inner third of the clavicle, and long oblique. In a case of this kind he had resorted, with good effect, to a modification of Moore's figure-of-eight bandage, which consists in making a clove-hitch around the arm near the elbow.

More recently he had devised an apparatus of his own, which seems to possess all the advantages of the other dressings in use, and also some peculiar to itself. In this the elbow, secured in a leather sling, is drawn inward and backward by means of straps passing to a padded band, which is placed in the axilla of the opposite side, and fastened over the shoulder. A boy, in whose case a perfect result had been secured, was shown wearing the apparatus, and photographs were also shown which were taken before the latter was applied, exhibiting very marked deformity, and at the conclusion of the treatment.

In fractures of the condyles of the humerus, he said that he was convinced that the active combating of the inflammation usually manifested in the joint, is the

Digitized by Google

only safeguard against anchylosis. When only one of the condyles is implicated, the ordinary anterior splint is generally efficient; but when the fracture involves both condyles, constituting what is known as a T fracture, he has found the usual methods of treatment quite inadequate. A varied experience, full of disappointments, in the use of the known splints in the more severe fractures of the condyles, had set him to work to make a splint with the following requisites:

(1) To hold the fragments firmly in apposition.

(2) To allow the forearm to be flexed and extended, pronated, and supinated.

(3) To lengthen or lessen the external lateral angle of the arm with fixation.

(4) To leave the entire elbow exposed for the purpose of making local applications during the whole time of wearing the splint, without disturbing the latter.

Such a splint he had accordingly devised, and he now exhibited it, consisting of two rods of untempered steel, with ball-and-socket joint, and fixation screws at the elbow and wrist; the rods being secured to the arm and forearm by means of plaster-of-Paris bandages. It had long been a mooted point among surgeons, he said, how soon passive motion of the joint should be commenced; some claiming that this should be at the end of a week, and others, not for three or four weeks. For his own part, he thought that the character of the injury in any given case should regulate the time for beginning passive motion.

In speaking of the treatment of Colles's fracture, he said that he had also devised a splint of his own for this; but his experience with it had not, up to the present time, been sufficiently large to warrant him in expressing any definite opinion in regard to its merits. He said, in conclusion, that he wished emphatically to protest against any splint whatever being left on for a week or more in any case of Colles's fracture. It is his own practice to remove the dressing every other day, and he said that unless this is done, deformity is very likely to result. To illustrate this, he mentioned a case in which a splint was allowed to remain on uninterruptedly for two weeks, when it was replaced by a plaster-of-Paris bandage, which was not disturbed for six weeks. The result was a very bad arm. In the course of the paper Dr. Smith also reported a large number of illustrative cases occurring in his own practice.

DR. JOSEPH D. BRYANT said that the cause of the deformity in fracture of the clavicle had been the subject of much dispute among surgeons; but in his opinion it depends simply on the fracture of the bone, and not on the action of any particular muscle or set of muscles. He spoke of the difference in the deformity according to the situation of the fracture, and said that he could not agree with the author of the paper that it is due, at least to any great extent, to the action of the subclavius muscle. If in the cadaver the clavicle be fractured, and the body hung up, it will be found that the same deformity results as in the living subject; and, therefore, it seems hardly likely that it is produced by muscular action. As to the method of treatment to be resorted to in this fracture, any apparatus that meets the indications present will secure a good result; though some of the dressings employed no doubt have special advantages. The Sayre dressing meets the indications, and he has used it frequently, with good results. The same is true of Moore's and others. In the same way, Dr. Smith's apparatus fulfils the indications, so far as he could judge from what he had seen of it to-night, and it seems to have the advantage over many others of greater comfort to the patient. This is an important point, and altogether he was much pleased with the dressing; so that he should like to give it a trial as soon as the opportunity occurred. On account of the lateness of the hour, he said that he did not feel that it would be right to discuss the other points mentioned in the paper.

DR. ALFRED C. POST spoke briefly of the different degrees of deformity produced by the location of the fracture at different points in the clavicle.

DR. GERLICH said that in one case in which he had employed Sayre's dressing he was obliged to remove it in a week on account of the discomfort which it caused the patient. After this he applied an ordinary bandage on the same principle as the apparatus devised by Dr. Smith, and the result had been entirely satisfactory.

DR. SMITH, in closing the discussion, said that, following Hamilton, he divided the clavicle into three thirds, and that deformity is always greatest when the fracture is situated in the middle third. As the insertion of the subclavius occurred at this part of the bone, it seemed reasonable to attribute the more marked deformity here to the action of this muscle.

THE REPORTING OF CONTAGIOUS DISEASES.

DR. C. R. AGNEW presented a resolution, which was unanimously adopted, to the effect that in the opinion of the Academy any judicial action which tends to prevent the early reporting to the Board of Health, on the part of the medical profession, of cases of contagious diseases, is contrary to public policy and detrimental to the public health.

PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated Meeting, October 26, 1885.

THE VICE-PRESIDENT, CHARLES K. MILLS, M.D., IN THE CHAIR.

DR. HENRY M. WETHERILL, JR., read a paper on

HYOSCINE HYDROBROMATE.

We do not, as yet, know accurately the history of the discovery and introduction of this most important and valuable therapeutic agent; but certain it is that Landenberg, of Germany, was the discoverer of hyoscine and the first to investigate its properties. His observations were seconded by those of Edelfsen, Gnauck, Emmert, and others on the Continent. The English current medical literature has, I think, not made mention of it. To Dr. Horatio C. Wood belongs the credit of being one of the first to investigate its action in this country, as seen in his admirable monograph published a few months since.

It is said that hyoscine is prepared by a rather complicated process from the alkaloid hyoscyamine by treating the latter with baryta-water. The pure alkaloid hyoscine is so volatile and perishable that it is not available as a therapeutic agent unless combined with acids, which form with it salts of fair stability. Those at present found in the drug market are the hydriodate, hydrobromate, muriate, and, I think, the sulphate. My

Digitized by Google

experience has been wholly with the hydrobromate, and it is this salt alone of which this paper treats. The most reliable is that produced by E. Merck, Darmstadt, whose three accredited agents in New York are Lehn & Fink, Schieffelin & Co., and Eimer & Amend. It can be obtained of the leading pharmacists of this city. In its gross physical appearance it resembles small crystalline masses and granules of potassium bromide. It is light in relative weight, opaque white, but not purely so, slightly inclining to be yellowish, rather deliquescent when exposed to the air. Seen under the microscope, it was very evident that its crystallization had been facilitated by stirring, as much of it was in very irregular, granular masses; but when allowed to evaporate spontaneously from its aqueous solution, it showed under the microscope handsome quadrahedral crystals springing from a granular base. These were entirely free from extraneous matters, transparent, and highly refractive. The literature of hyoscine is rather meagre in America; brief notices of it are to be found in the more recent works on therapeutics and materia medica. The other works devoted to this subject are Dr. Wood's monograph, the paper by Dr. Judson B. Andrews found in the *American Journal of Insanity* for October, 1885, a paper emanating from the Hudson River Hospital for Insane, in the *Medical Record*, 1885, and some papers from the pen of Prof. John M. Maisch in the *Philadelphia Journal of Pharmacy* for November, 1885.

Hyoscine hydrobromate is freely soluble in cold distilled water; but it will be found desirable to add to this menstruum ten per cent. of alcohol as a preservative. The following I have found to be a convenient formula:

℞.—Hyoscine hydrobrom. . . . gr. j.
Aqua destillat. . . . . f ʒix.
Alcohol . . . . . f ʒj.—M.

In every ten minims of this solution there is $\frac{1}{60}$th of a grain of the hyoscine hydrobromate. In prescribing the compounds of hyoscine care should be taken plainly to write in full the name of the salt, so as not to mislead the pharmacist with the impression that hyoscyamine has been ordered, and *vice versa*, as the hyoscine salts are far more powerful than are those of its sister alkaloid. Now thus having described the substance at some length, what have we found to be its exact physiological effects, and what do we find to be its true place in therapeutics after a very careful and painstaking study of its action which has extended over a period of six months upon the patients under our care in the Pennsylvania Hospital for the Insane? Before answering this question let me recount the effect produced upon myself by a very moderate dose taken by the mouth. I was in health at the time. Dose, $\frac{1}{120}$th of a grain. Before administration, pupils normal, equal; pulse 88, good; respiration 20 per minute; skin normal; temperature 98° F. Within 45 minutes the pupils were evenly and moderately dilated, the voice was hoarse, face suffused, conjunctivæ injected, temperature raised to 99.5° F., respiration full, slowed to 16 per minute, pulse slowed to 64, very full, considerable general relaxation of muscles, decided general sweat, impaired coördination, and a sense of fulness in the head and of wretchedness. I managed somehow to get to bed, and at once fell asleep, and so continued for nine hours. Awoke much refreshed, no ill effects, everything normal but the pupils, which were yet slightly dilated, but which regained normal conditions within two hours.

Now, in regard to our results as obtained by its use in the hospital. We have no hesitation in saying that as a hypnotic and sedative it has proved most valuable in our hands. As a hypnotic, the usual range of dose is from $\frac{1}{120}$th to $\frac{1}{60}$th of a grain, given at bedtime, preferably by the mouth—very frequently a less dose than gr. $\frac{1}{120}$th will be sufficient; gr. $\frac{1}{200}$th has often acted better in insomnia than has a larger quantity. It is seldom necessary to repeat the dose; and another very decided advantage possessed by hyoscine over hyoscyamine is that small doses can be continued for a long time without increase, whereas, the patient soon tolerates small and then moderate quantities of hyoscyamine, and, finally, resists even very large doses of it. We have given hyoscine a thorough trial in the insomnia occurring in the course of acute delirious mania, and with marked success, having succeeded, when all the usual modes of treatment had proved inadequate, in securing for the patient from six to ten hours of quiet sleep nightly for the past nine weeks, with but four or five exceptions; but one dose in every twenty-four hours, at bedtime, the amount ranging from gr. $\frac{1}{120}$th to $\frac{1}{70}$th. The insomnia in these cases is one of the chief elements of danger. If it is possible to give such a case a fair amount of sleep and of nourishment in a concentrated form, the probability of a favorable issue may be entertained. The insomnia of agitated melancholia, of the morphia habit, of alcoholism, of acute mania, of neurasthenia, of chronic mental disorder, with habitual wakefulness and motor activity, and in those confirmed cases of insomnia from unascertained cause, which usually prove so obnoxious to treatment, hyoscine has been found to answer a very good purpose. It does not invariably succeed; but the failures have been very exceptional. In many instances the chronic insomnious habit has been broken so as to permit of the withdrawal of the hypnotic. It is a severe test of the value of any hypnotic to administer it in daytime, and the drug under consideration has been found to act very well even under this condition. It seems scarcely necessary to refer to the unsatisfactory and often disappointing action of the hypnotics which are now in general use, and it would seem as though this remedy is the one for which rational therapeutics have waited for so long a time.

Now, as to its usefulness as a general sedative, we have had results which justify the assertion that it is the very best means at present at our disposal for calming the motor excitement of acute and chronic mental disorders, in their talkative, active, noisy, destructive, or violent phases. In this class of cases the range of doses may sometimes have to be greater than in the treatment of insomnia, from gr. $\frac{1}{120}$ to $\frac{1}{50}$. I have seldom been obliged to give so much as gr. $\frac{1}{60}$, and have rarely had to give more than one dose in twenty-four hours. As an occasional exception, a patient has been found whose excitement has successfully resisted a full dose; but it must be remembered that some cases of chronic mental excitement have been dosed with varying success through a period of years, until a peculiar condition of resistance to, and toleration of, remedies of this class has become established. Where a large number of excited patients are congregated, even though they may be

Digitized by Google

classified with care, there are a few who seem to be the cause of most of the general disorder and confusion; reduce these few to a condition of comparative quiet, and the larger, but less aggressive, element remains tranquil. Following out this theory in the administration of hyoscine, we have had the satisfaction of seeing wards for excited patients quite transformed in character for the better; nor can this be fairly termed "medical restraint."

I have tabulated carefully our study of the physiological action of this remedy as a hypnotic and as a sedative, and have also tabulated our experience with hyoscyamine as a hypnotic. We had found the latter so decidedly inferior to hyoscine as a sedative that it was not deemed necessary to tabulate these results; but it must not be inferred from this that hyoscyamine is inert. It is a remedy of no mean value, and only second in activity to its sister alkaloid.

The tabulated statements to which reference has been made will appear in the forthcoming Report of the Committee on Lunacy of the Pennsylvania State Board of Charities for 1885.

Physiological Effects.—The physiological effect of a full dose of hyoscine—say, gr. $\frac{1}{60}$—is manifested within twenty minutes. These are brief, transitory bewilderment, marked interference with coördination, widely dilated pupils, slow, regular, very full pulse, dryness of the throat, relaxation of the vocal cords, very slow, full respirations, sometimes becoming Cheyne-Stokes, marked effusion of the face and of the general surface of the body, a slight rise in temperature, and free diaphoresis, which does not seem to restore normal temperature. There is general muscular relaxation, and a sense of wretchedness. Sleep usually follows, which continues from one to five hours, if the dose is given in daytime and the patient is not put to bed. This amount administered at night would be followed by sleep lasting for eight or ten hours. The mydriatic effect is rather transient, but usually persists through an entire day. The pulse is slowed about twenty beats per minute, and this effect gradually wears away during eight or ten hours, and is often followed by a very variable period of pulse acceleration, which seems to be simply a reactionary hastening of the pulse to restore the disturbed balance of the circulation. The normal rate of respiration is gradually restored through a period ranging from three to five hours.

The rise in temperature is not an invariable result, and is frequently small—seldom exceeding one and one-half degrees—and the balance of temperature is usually restored within two or three hours. Dryness of the throat often persists through an entire day. Suffusion of the surface of the body is usually transitory. In moderate and in small doses the effect is, of course, proportionate to the amount employed; but the same general symptoms are present and the patient is quieted accordingly. Interference with the appetite is sometimes observed. It does not seem to act upon the bowels nor upon the kidneys.

Hyoscine is not always well borne; occasionally the following symptoms have followed the use of a moderate dose: Nausea, vomiting, anorexia, dysuria, syncope, with small, rapid, irregular pulse, and with symptoms of partial paralysis of the pneumogastrics. This untoward condition occurred in a case of epileptic mania, in one of paretic dementia, in one of chronic dementia with excitement, and in one of acute hysterical mania. All of my personal experience of the action of hyoscine has been among females, and they are, I think, more susceptible to its action than are males. This is generally true of many drugs. Hyoscine is a spinal sedative of considerable activity. It has a decided influence over the spasms of a case of tetanus: a powerful man, whose life it certainly prolonged for some hours, and who died, not from convulsions, but from high temperature—this was, I think, 108° F. before death; but post-mortem, it rose to 116° F. This case was not mine, but I know that the observations were accurately taken with a corrected thermometer. Is it best to give the remedy hypodermically or by the mouth? It acts almost immediately, and in rather less dose, by the former method; yet we have preferred usually to give it by the mouth, as it acts very promptly when taken into the stomach, even in very small doses, and this method suffers no shock to an excited or timorous patient.

Among the physiological effects of hyoscine, one or two observers claim to have frequently noticed a primary acceleration of the pulse-rate, previous to its becoming slow and full. This I have not found to be the case, save in two instances, and even in these two cases the effect was not invariable. There is a source of possible error to be here taken into consideration—that the mere act of feeling the pulse, or even addressing some persons, causes a marked acceleration of the pulse, which may persist for some time should the patient be excited, timorous, apprehensive, or nervous.

From three observers of the action of hyoscine in another State, comes the report that their anticipations of the good effects of the drug had not been realized, after fair trial of an article which they thought was reliable; but there is reasonable ground for doubt that the substance employed emanated from Merck's laboratory. The evidence that it is a hypnotic and sedative of great value to the profession is rapidly accumulating. We have thus far found the different samples of Merck's hyoscine hydrobromate to be uniform in effect and in external characteristics, and are much pleased with its action. It has been in daily use and under close observation in our hospital practice, and we prescribe it with confidence in its activity. It is preferable to the other sedatives and hypnotics, as it is more certain and uniform in effect, convenient to administer, and free from injurious secondary effects.

DR. D. D. RICHARDSON said it had been his experience to find that hyoscine caused dilatation of the pupils. In some cases the pupils remain dilated for a few days; but, as a rule, the dilatation disappears sooner. The pulse was always much increased; with the exception of one case, it was always above 120. Respiration increased often to 40 per minute. He agreed with Dr. Wetherill as regards rise of temperature and increased respiration. The appetite is not influenced by the use of the drug. The secretions, he said, were generally increased, especially the kidneys. No constipation resulted from its use.

DR. CHAPIN had been a daily observer of the experiments of Dr. Wetherill, and entirely concurred with his remarks. He said he had always found the pulse to be hurried. The sleep which resulted from its use lasted from eight to ten hours. He thought the difference

Digitized by Google

of opinion of the physiological action of the drug might be due to different preparations of it.

DR. WETHERILL, in conclusion, said that the dryness of the throat was very decided. There was also a relaxation of the muscles of the throat.

DR. G. BETTON MASSEY read a paper on

THE PRINCIPLES GOVERNING A CHOICE OF CURRENTS IN ELECTRO-THERAPEUTICS.

He pointed out the value of more accurate conceptions of the differences in the physical character of faradic and galvanic currents as a basis for their intelligent selection. The therapeutic value of faradism is due entirely to its electromotive pressure, while the most useful medical quality of the galvanic current is its volume. Electromotive pressure and electric volume are essentially different articles of the materia medica, and should be so considered.

The therapeutics of "volt-pressure" applications were reviewed, including the differing indications for slow succession and rapid succession faradic currents, and were contrasted with the therapeutics of "milliampère-volume" applications. The paper concluded with the statement that the faradic current presents the best form of electricity for the treatment of those diseases in which a stimulation of mobility or sensibility is either directly or indirectly curative, with the single exception of disorders characterized by the appearance of degenerative response, while the constant galvanic current may be relied upon to fulfil the remaining possibilities of electricity in medicine.

MONTREAL MEDICO-CHIRURGICAL SOCIETY.

Stated Meeting, December 4, 1885.

THE PRESIDENT, T. G. RODDICK, M.D., IN THE CHAIR.

BLACK GALLSTONES.

DR. RICHARD MACDONNELL exhibited a number of gallstones which had been removed from a dissecting-room subject. The stones were of a jet-black color, and resembled peppercorns in shape and size. When dry they were very friable, breaking with a resinous fracture and being easily reduced to a powder resembling India ink. This kind of gallstones, though rarely met with, has been described by Budd, who gives an excellent colored illustration of them. They do not contain cholesterine, but are made up of bile pigment and lime.

APPENDIX VERMIFORMIS COMMUNICATING WITH THE ILEUM.

DR. MACDONNELL also exhibited a specimen of appendix vermiformis which had formed a communication with the ileum about an inch from the valve. A probe could be passed through the appendix into the ileum. It was thought that the attachment to, and communication with, the ileum was due to a concretion which had previously existed in the appendix and had caused adhesive inflammation; as the specimen was taken from a dissecting-room subject, there was no history.

THROMBOSIS IN THE LEFT VENTRICLE OF THE HEART.

DR. GEO. ROSS showed a heart which had been removed by Dr. Johnston from a patient who lately died in the General Hospital. Both sides of the heart were greatly distended and there was marked bulging of the wall of the left ventricle just above the apex. The cavities contained soft blood-clots. There was no clot in the pulmonary artery or its branches. On opening the left ventricle a firm, decolorized, and apparently organized thrombus was found filling the spaces between the columnæ carneæ in the vicinity of the septum and projecting slightly into the cavity at a point corresponding to the bulging previously mentioned. The thickness of the thrombus exceeded that of the ventricular wall, which in places was reduced to one-fifth of an inch. A space between the thrombus and the heart wall was filled with a chocolate-brown fluid and the endocardium seemed to have disappeared. At some points the heart muscle was pale and in part fibroid. A small, firm, decolorized clot was also seen lying loosely behind the left coronary segment of the aortic valve, from this was prolonged a clot which completely plugged the left coronary artery. A small, firm clot filled the left auricle. Valves normal.

Dr. Ross remarked that the patient was a strong, healthy girl about twenty-five years of age who came into the hospital to be treated for an ulcer of the leg which was supposed to be of syphilitic origin. Suddenly she was seized with a violent pain in the left side of chest and great difficulty of breathing; her pulse was almost imperceptible at the wrist, and she was in great distress. The dyspnœa and pain grew worse and the patient gradually sank, and died five days after the first seizure. Dr. Ross at first thought it was a case of pulmonary embolism but was now at some loss to account for the symptoms.

DR. ARMSTRONG suggested that the clotting of the blood in the left coronary artery and the consequent loss of nutrition might, perhaps, account for the symptoms observed before death.

DR. T. WESLEY MILLS suggested that possibly the plugging of the coronary artery might explain the other clots and the peculiar symptoms, the lower clots being formed by the weakening of the heart's action due to loss of nutrition from plugging of the left coronary artery. In such an enfeebled heart a murmur could scarcely be expected to be heard, the obstruction to circulation and interference with nutritition giving rise to pain and disturbance of action of the pneumogastrics. Dr. Mills, in conclusion, remarked that there were other cases reported with the same symptoms, due to plugging of the coronary artery alone.

ENCYSTED CALCULUS OF THE BLADDER.

DR. SUTHERLAND showed, for Dr. Arch. E. Mallock, of Hamilton, Ont., a bladder with an encysted calculus. Dr. Malloch's report was as follows: J. C., æt. 76, had cystitis of one year's standing, due to catheterization, necessitated by retention of urine, the result of hypertrophy of the prostate gland. The bladder had been sounded for stone on two occasions, and explored with the finger by an incision made in the perineum, but no stone was discovered; the bladder was drained through the perineal incision, but no appreciable relief followed, and the man died four days after. On examining the bladder post-mortem, its coats were found to be much hypertrophied, and the prostate of large size. The summit presented a diverticulum a third the size of the

Digitized by Google

whole bladder, and contained a calculus the size of a small marble, and composed of triple phosphates. The communication between the bladder and diverticulum was of small size, and would only admit a lead-pencil.

ELEPHANTIASIS OF THE LEG.

DR. SUTHERLAND exhibited a remarkable specimen of elephantiasis of the left leg, which had been sent to the Museum of McGill University by Drs. Gooding and Greaves, of Barbados. The leg had been removed from a negro aged 23, who had suffered since the age of 11 from attacks of fever. After each attack the leg increased in size, until, from the great inconvenience it caused him, he decided to have it amputated. The enlargement commencing about three inches below the knee-joint, it was decided by Drs. Gooding and Greaves to preserve the joint. Whilst amputating, but little blood was lost, but some four pints of lymph escaped. The man survived the operation only nine days, dying of pyæmia. The leg, after being preserved some time in alcohol, measures around the calf twenty-five and a half inches, instep twenty-one inches.

FRACTURE OF THE SPINE.

DR. SHEPHERD presented a specimen of fracture of the spine, which had been removed several days before by Dr. W. Johnston from a patient who had been under his care some three years before. The man, three winters ago, whilst cleaning the snow from the roof of a house, missed his footing, and fell to the pavement below, a distance of some fifty feet. He was immediately brought to hospital, and, on examination, it was found there was a fracture of the back in the lumbar region. There were great swelling and deformity of the parts and complete paralysis of sensation and motion of legs. He had also incontinence of urine. The patient remained in hospital some months, regaining, after a few weeks, partial sensation and motion. The deformity very much lessened after the effusion was absorbed. He was discharged from hospital in the spring of 1883, and could walk about fairly well. He even took a situation as coachman for some time after leaving hospital.

This spring he hired himself out as assistant gardener, and said, whilst digging one day, felt something give way. Then he had severe pain and some swelling at site of the old injury, and lost the power to use his leg. He was brought to hospital, and it was found there were some swelling and great tenderness at site of old injury in lumbar region, complete loss of sensation, and but little power of motion in lower extremities. After being in hospital a week or two, he developed phthisical symptoms, and was transferred to the medical wards. He died of phthisis a few days ago, and at the post-mortem the vertebræ of the lumbar and lower dorsal regions were removed. The specimen showed slight left lateral curvature, with moderate angular curvature opposite the second lumbar vertebra. On making a vertical section, the body of the second lumbar vertebra was seen to be partially absorbed, and a ring of bone encroached upon the cord at this spot. There was a fracture of the spines of the second and third lumbar, and the invertebral substance between these two vertebræ had completely disappeared. There appeared to have been a fracture, also, of the lamina of the second lumbar. The cord and membranes disclosed nothing to the naked eye, and were removed for further examination.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, November 24, 1885.

THE PRESIDENT, CHARLES MCBURNEY, M.D., IN THE CHAIR.

DR. C. T. POORE read a paper on

EXCISION OF THE TARSAL BONES.

Disease of the tarsal bones is not an uncommon occurrence among children who apply for admission into hospitals. The following paper is based upon nine cases operated upon at St. Mary's Free Hospital for Children. Although there is nothing very noteworthy in any of the cases taken individually, yet when taken together they form a group from which one may draw a few practical deductions.

The following plan of operation was followed in all but one case, to which reference will be made further on. After rendering the limb bloodless by an Esmarch bandage, if the os calcis is to be removed, an incision is made from a point corresponding to the inner edge of the tendo Achillis and about an inch above its insertion, outward and then forward on the outer aspect of the foot to a point midway between the external malleolus and the proximal end of the fifth metatarsal bone, the incision being made directly down to the bone. The only tendons denuded are the tendo Achillis and that of the peroneus longus where it passes over the lateral surface of the os calcis. No vessel of any size requiring ligature is divided. The incision will be found to afford plenty of room. The periosteum is then divided and separated from the bone as far as possible with an elevator; it will then be found that the bone can be removed either as a whole or in pieces, the ligaments being divided as they present themselves. After removing all the bone and well washing out the cavity left by the operation, the constricting bandage is removed, and any bleeding points secured. The edges of the incision are brought together with silver wire, except at the posterior part of the wound, which is left for a drainage tube. I use silver wire because, in my experience, it is often necessary to hold the parts in coaptation longer than can be done with catgut. The foot is usually put up in a tin leg splint with a foot-piece at right angles to the leg. The cavity left after the removal of the bone is in some cases swabbed out with chloride of zinc, in others dusted over with iodoform. None were put up in a permanent dressing. The following is an abstract of the cases.

Case I.—F. M., three years of age, came to the hospital in 1874. She was an unhealthy-looking child. There was a large sinus from which there was a considerable discharge, situated upon the dorsal aspect of the right foot over the upper border of the cuboid bone. There was also disease of the first metacarpal bone of the left hand.

In September, 1874, the patient was etherized, and the disease was found to be confined to the os calcis. This was freely gouged, so as to remove all diseased bone. The portion left seemed hard and was supposed

Digitized by Google

to be healthy. In January, 1875, as the wound did not close, some more diseased bone was removed. In April, as the foot was no better, an incision was made by splitting the tendo Achillis and then extending the incision forward upon the plantar surface of the foot, so as to afford room to remove the remains of the os calcis. The cavity thus left was stuffed with lint. The wound gradually filled up and she was discharged with her foot in good condition, the heel somewhat flattened and with a deep cavity behind.

Upon examination, November 1, 1885, eleven years after the operation, the foot was found in good condition. There had been no return of disease, no pain about it, and the child walked with but a very slight limp, scarcely perceptible. The heel, where there was a deep depression at the time of discharge, had filled out, so that the point of excision was represented by a mere line, occupying the posterior rather than the plantar aspect of the foot. The contour of the heel had filled out. There was obliteration of the plantar arch. I do not think that there had been any reproduction of bone.

Case II.—M. D., aged three and a half years, had had disease of the os calcis for some time. The bone had been gouged twice before coming to the hospital, but without any permanent relief. He was a healthy-looking boy. There was a sinus on the external aspect of the foot over the os calcis, through which diseased bone could be detected. In February, 1879, the old line of incision was reopened. There was found a sinus in the os calcis leading to a cavity in which was a loose piece of bone about the size of a filbert. The walls of this cavity were smooth and hard. The necrosed bone was removed, and the wound closed, in the expectation that the cause of irritation being removed recovery would take place, but after a time the parts assumed the same condition that existed before the operation. In May the bone was excised. It was found harder than normal. After the last operation the patient made a good recovery, and was discharged walking well. He has not been seen since his discharge from the hospital.

Case III.—M. R., aged seven years, was admitted February, 1879. Three months previous she began to complain of pain in the heel of the right foot. It then began to swell, and three weeks before coming under observation an abscess opened posteriorly, and has continued to discharge since. Diseased bone could be detected with the probe. In March the os calcis was removed. It was found entirely diseased. She was discharged from the hospital in June, able to walk well. She was seen November 29, 1885, when she walked well, with scarcely a limp, had no pain, and the old line of incision had not reopened. About one year ago, five years after leaving the hospital, an abscess formed on the dorsal aspect of the foot, and has continued to discharge ever since. There is now a sinus at this point. The patient seems healthy, and experiences no inconvenience from the foot. I presume there is diseased bone. There has been some reproduction of the os calcis.

Case IV.—Sarah J.; four years before admission received a cut on the plantar surface of her right foot from a piece of glass. The wound has never closed. Three years ago some diseased bone was removed, and since then several small pieces have come away. In November, 1879, the os calcis was removed. The bone was extensively diseased. In February she was discharged, able to walk well.

A week after her discharge she was brought to the hospital with a superficial abscess about the point of operation, caused, it was said, by walking with a badly fitting shoe. She was sent home in a few days. In May, 1883, her friends reported that she had had no further trouble, and that she walked well.

Case V.—C. R., ten years old, came to the hospital March, 1881, with the following history: Six months before, without known cause, a swelling appeared at the back of the heel, an abscess formed and opened, and has continued to discharge ever since. The os calcis was removed, and was found to be much diseased. He was sent home in June with a useful foot. Was seen November 20, 1885. There has been no change in the foot since leaving the hospital; can walk well, with but little, if any, limp, and is now employed as an errand boy in an apothecary's shop. There is, however, limited motion at the ankle-joint. There does not appear to have been any new bone formed.

Case VI.—Peter H., an unhealthy-looking boy, about six years of age, was admitted September, 1881. He had disease of the right os calcis, and carious bone in various portions of his body. In October the os calcis was removed. He did well for a time, then his foot began to swell, the old line of incision opened, and he was in a worse condition than before the operation. Other tarsal bones became involved in the disease. The bones were gouged, but with no improvement. In March, 1883, Syme's amputation was performed. The flap did well for a time, but finally sinuses began to form, and he was removed from the hospital. On examining the parts after removal, there was found considerable reproduction of bone.

Case VII.—K. A., three years of age, was admitted January, 1882, with disease of the os calcis of some duration. The bone was removed February, 1882. She was discharged April 20, the wound all closed, and able to walk well. Nothing has been heard from her since she left the hospital.

Case VIII.—Joseph M., six years of age, came under observation in February, 1882, with a history of disease of the bones of the left foot of some duration. There was a sinus over the astragalus through which carious bone could be detected. The foot was much swollen. On March 20, 1882, the sinus over the astragalus was enlarged, and that bone removed by gouging. It was then found that the anterior portion of the os calcis was diseased. The anterior two-thirds were removed through an incision on the external aspect of the foot, leaving the posterior portion of that bone. The foot did well for a time, the anterior part of the incision closing, but a sinus persisted posteriorly. In October, as the portion of the os calcis left was evidently diseased, it was removed. After this the wound closed, and he was discharged with a sound and useful foot. He has not been heard from since.

Case IX.—Edward L., two and a half years of age, was admitted September, 1882, with an extensive swelling on either side of the left ankle-joint. Fluctuation was marked. He had been lame for some months. The abscess in the ankle-joint was opened under ether. The lower end of the tibia and the articular surface of

Digitized by Google

the astragalus were found denuded of cartilage. The diseased bone was gouged and the joint drained. The abscess continued to discharge for some time, and then the sinus closed about the ankle-joint, but a new opening formed over the anterior surface of the astragalus in front of the ankle-joint. Later, the astragalus and os calcis, which were found diseased, were removed. At the time of the operation there was no disease about the end of the tibia, and the bone was well covered. Patient was discharged from the hospital with a useful foot, all sinuses being closed. November 19, 1885, he was seen at the hospital. He has had no trouble with the foot since, can walk well with a slight limp. The end of the tibia occupies a lower plane than that of the sound limb, so that the ankle-joint is depressed. There has been some reproduction of bone.

Of these nine cases, the os calcis was alone removed in seven, the os calcis and astragalus in two. A useful foot was obtained in eight, and in one amputation had to be performed. In but one of these eight cases has there been any return of the disease in the other tarsal bones, and in this, not until five years after the operation. All but three cases have been seen or heard from within the past year, and in all, with but one exception, the foot has continued in good condition, and the patient able to walk and be about with other children without any inconvenience except a slight limp. In all, there has been obliteration of the plantar arch, and a tendency to walk upon the inner border of the foot. All complain that the inner side of the shoe is worn out first, but there has been no pain.

In regard to a partial removing or gouging of the os calcis for disease, my own experience has not been flattering: although a faithful trial of this procedure was made in four cases, no permanent cure was obtained, and only after total extirpation of the diseased bone did the sinus close. In one case the bone had been operated upon three years before admission, with no apparent benefit.

Case II., where there existed a sinus leading into the centre of the os calcis, in which was imprisoned a loose piece of dead bone, seemed very favorable for such an operation, yet the operation failed to arrest the disease and a total excision of the bone had finally to be performed. In another case the posterior third of the os calcis was left, it being apparently healthy, but recovery did not take place until this, too, had been removed. I am well aware that others have obtained good results from partial excision or gouging, but perhaps it was in older subjects and under more favorable circumstances. My own experience is entirely opposed to a partial operation in children. Perhaps one cause of the want of success in these cases is the fact that the bone was sclerosed and incapable of filling up the cavity left by gouging.

I have never made a resection of the ankle-joint in children; although I have seen some cases of disease of this articulation in which the lower end of the tibia and fibula were extensively diseased, they made a good recovery.

DR. H. B. SANDS said that it seemed to him that a distinction must be drawn between tubercular inflammation and osteomyelitis of the os calcis. So far as he had been able to judge while listening to the paper just read, Dr. Poore had reported only one case of true necrosis of the bone. In this there was a cavity with healthy walls, enclosing a piece of dead bone, which was removed by operation because the cavity would not close.

It was further stated that in this case when the os calcis was removed it was found to be firmer than normal, which would imply that it was not carious, and that the previous failure to obtain a cure was, as Dr. Poore had intimated, due to a refusal on the part of the bony cavity to fill up.

Dr. Sands doubted the necessity of removing the entire os calcis in cases of necrosis unless the necrotic process involves the entire bone, the indication being to remove only the loose sequestra. He recalled a case which occurred about fifteen years ago in a lad ten years of age, who was supposed by Dr. Van Buren, Dr. Parker, and himself, to be suffering from caries of the tarsus. There were several sinuses in the foot, and it was advised that the foot should be amputated. But an exploratory incision was made, and the os calcis was found to be a shell containing a large number of pieces of dead bone within a cavity which had a smooth lining such as is usually found in bones containing necrotic tissue. The pieces of dead bone were removed, and, although the walls of the os calcis were exceedingly thin, the cavity filled up within a few months, and the wound healed.

He had not had much experience in dealing with the os calcis in children, but in adults he thought partial excisions are often successful. He was somewhat surprised to learn that caries is so often limited to the os calcis. His own experience had been that this disease is rather apt to attack the astragalus and scaphoid, and other bones of the tarsus, rather than the calcaneus alone. He thought the tendency nowadays is to avoid excisions in cases of caries, and that the use of the gouge or the sharp spoon often gives satisfactory results, and enables the surgeon to be conservative to the fullest extent.

He believed that in one of the children presented the condition of the foot corroborated the statement which he had made a month ago, that after the removal of a large portion of the tarsal bones, provided the periosteum is left, considerable reproduction will occur. It was evident in that case that, although the entire os calcis had been removed, there had been a considerable reproduction of bone. It seemed to him to be a point worthy of consideration whether, in caries, excision should be preferred to an operation which is partial and which aims to remove only the diseased tissues. It may occur, however, that if a large part of the interior of the os calcis is removed the space may remain open, although much may be done to overcome that difficulty by nailing down the parts or fastening them by deep sutures. He was willing to admit, however, that the results obtained in Dr. Poore's cases were excellent.

DR. POORE said that almost all the cases he had reported were in the hospital for a long time, and that in those in which gouging had been performed the interval between the gouging and excision was in some cases one year at least. He had given the cases all the chances of recovery he could, but as suppuration had

Digitized by Google

continued and the condition of the tarsus had not improved, and small pieces of bone had worked out, he resorted to excision.

DR. SANDS asked whether it is good practice to leave a case for one year after an operation. Is it not rather desirable to follow one operation by another with a view to removing all the diseased tissue as quickly as possible?

DR. POORE said he performed gouging in one case four times within one year. He had been very much disappointed in this operation. He certainly expected to see some cases get well after performing it, but he had never seen such a result. It might be because he had dealt with young children, the patients having been mostly under four years of age.

DR. LANGE recalled a very limited number of tuberculous affections of the os calcis and astragalus in which the disease was so limited that it was not necessary to remove the bones entirely. He had one such case where the principal seat of the disease was the bones of the ankle-joint, and there was also a tuberculous sequestrum in the os calcis which was removed, and the entire shell of the bone left, and finally recovery took place. He thought that in a good many cases of tuberculous necrosis recovery would eventually take place after sequestrotomy and scraping. It seemed to him that in Dr. Poore's cases a striking point was the difference between the reproduction of the os calcis and the astragalus—that is, there had not been a reproduction of the astragulus. In some of his own cases of total excision of the ankle-joint he had observed the same thing, and it was this probably which caused the amount of shortening in Dr. Poore's cases.

He had twice excised the first and second rows of tarsal bones during his service in Bellevue Hospital, and also cut away the surface of the os calcis and astragalus in one instance; in the other the extirpation was not so extensive: the result was a good one, although the patient was an adult person. The result in the first case he could not give, for the patient was removed from the hospital because she refused a secondary operation. The results of other surgeons are rather encouraging for operative interference—for instance, those reported by Neuber some years ago.

NEWS ITEMS.

NEW YORK.

(From our Special Correspondent.)

TRICHINOSIS.—The occurrence of eight cases of trichinosis among the members of a German family, who had previously enjoyed themselves at a birthday feast in which raw ham figured, is reported. There have been but four cases of the disease in this city since its discovery, and it would seem that imported ham was responsible in every instance.

A COCKROACH IN THE EAR.—Dr. Samuel Sexton, author of the admirable article in *Nature* the other day upon tinnitus as a disturbing factor in auscultation, recently presented to his class a case in which a cockroach was found in either ear. The boy had complained for four days of a "kicking noise," and examination revealed a very lively roach in the right ear. He referred to symptoms of the same kind from which he had suffered four years before; a further search revealed a second dead cockroach in the other ear.

FOUR CASES TO BE SENT TO PASTEUR FOR INOCULATION.—Four little children are to be sent to Pasteur for inoculation with the virus of hydrophobia, they having been bitten by mad dogs in Newark, New Jersey. They sail this week in the "Canada" in charge of Dr. Billings. Considerable rivalry seems to be manifested in the desire to manage the expedition, Mr. Carnegie, who founded the Bellevue Hospital Pathological Museum, having offered to defray all the expenses provided Dr. Biggs, of that institution, be permitted to engineer the enterprise.

THE COCAINE HABIT.—The case of the Chicago physician, whose exploits with coca have furnished the enterprising newspaper reporter with meat and drink for several days, has drawn forth an interview with a well-known throat specialist, who is in the habit himself of taking daily no less than twenty-five grains. He declares it a delightful stimulant, and states that no appetite has been so far formed.

MONTREAL.

(From our Special Correspondent.)

THE SMALLPOX EPIDEMIC.—The deaths from smallpox during the month of November reached the large number of 874. Still this is only a little more than half the number (1630) of deaths which occurred during the month of October. Up to the end of November the total number of deaths from smallpox was 3513. The hospitals are still full, and new wings are being opened. The old Hospital of St. Roch's is still occupied, notwithstanding the protests made by the Visiting Governors of the College of Physicians and Surgeons of Quebec Province. Among other things, they said: "Dirt, foul smells, and mismanagement are the characteristics of St. Roch's Hospital." Many patients who have been treated in St. Roch's have given most horrible details of the condition of the hospital and the methods of treatment. It is a perfect black hole of Calcutta, according to many. The doctor was incompetent, the nurses inefficient and neglectful, and the food (so-called) disgusting. Many dying patients could not get a drink a water. Still the Health Board deny everything, and endeavor to make the public believe that it is a perfect sanitarium, and no fault can be found with it, or the incompetent staff that run it. However, the profession are perfectly convinced that the place ought to be shut up, or rather burned down, and all the cases sent to the new hospital, where the air is good, the attendance fair, and there is plenty of room. I fear that we shall have smallpox with us for some time yet, as no efforts are being made to vaccinate the twenty French Canadian babes that are daily arriving and growing up unvaccinated. Fuel is thus continually being added to the flame. Until registration and vaccination are compulsory, smallpox, like the poor, will be always with us.

MEDICAL DINNER.—The annual dinner of the Undergraduates in Medicine was held on Thursday, the 3d of December, and was a most successful affair. About two hundred sat down, including several prominent citizens and public men.

Digitized by Google

MCGILL UNIVERSITY.—There are two hundred and sixty-five students attending the classes of the Medical Faculty of McGill University this session.

LONGUE POINTE ASYLUM.—The Longue Pointe Lunatic Asylum is still in a most unsatisfactory condition. The government, stimulated by Dr. Hack Tuke's *exposé* of the state of affairs at this asylum, appointed two additional medical men to look after the interests of the patients, and to treat them as they thought best. The sisters in charge of the asylum refused to accept those appointments, and continued on their own medical man, who is a mere tool in their hands, and also appointed an additional physician. Heretofore the patients have had no medical treatment except that prescribed by the nuns, the medical men being mere ciphers, and the government physician having power merely to admit and discharge patients. It was the intention of the government to give the patients proper medical treatment, but the sisters seem to have the upper hand, and simply defy the government, with whom they have a twenty-one years' contract to farm the lunatics. Of course the government, by stopping the supplies, could put an end to this state of affairs, but they have neither the desire nor courage to fight with such a powerful corporation as the Sisters of Providence de St. Jean de Dieu, backed by the whole Roman Catholic Church. We hope that in time the darkness of ignorance and superstition which now envelops us may be dispelled by the enlightenment, if not of the nineteenth, at least of that of the twentieth century. Then smallpox will be a dim tradition, and lunatics will be treated like human beings.

THE INTERNATIONAL MEDICAL CONGRESS OF 1887.—A meeting of members of the medical profession interested in the International Medical Congress in 1887, to which prominent medical men from a number of cities were invited, was held at the Hall of the College of Physicians, Philadelphia, December 4, 1885, Dr. D. Hayes Agnew in the Chair.

It was stated that official notice had been given of the election, as members of the present Executive Committee of the Congress, of Drs. J. S. Billings and J. M. Browne, of Washington, D. C.; Christopher Johnston, of Baltimore; George J. Engelmann, of St. Louis; and J. M. Da Costa and William Pepper, of Philadelphia.

A general and strong expression of opinion was made in support of the American Medical Association and its Code of Medical Ethics, and sincere regret was expressed that hasty action on the part of the Association, and the introduction of false issues, had imperilled the success of the Congress. It was made entirely evident, however, that the acceptances of the above elections would not be regarded as affording any adequate guarantee for the future scientific conduct of the Congress, and consequently would not be followed by any coöperation on the part of the leading members of the profession now unwilling to join in that work. As an evidence of the earnest desire which is felt for the restoration of harmony upon this subject, and for the reorganization of the Congress on a basis which would command general support, and thus insure success, the view was unanimously expressed that if the present Executive Committee should unite with themselves the Original Enlarged General Committee, and recommence the organization *de novo*, this course would insure the desired result.

THE EXECUTIVE COMMITTEE OF THE CONGRESS.—The present Executive Committee, acting under the provision by which its membership may be increased to thirty, elected, at a meeting held in New York last month, Drs. J. S. Billings, U. S. A.; J. M. Browne, U. S. N.; Christopher Johnston, of Baltimore; Geo. J. Engelmann, of St. Louis; J. M. Da Costa and William Pepper, of Philadelphia, of the Original Committee. We are informed that all these gentlemen have declined to accept the appointments.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 1 TO DECEMBER 7, 1885.

POLHEMUS, A. S., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Presidio of San Francisco, California, and ordered for duty as Post Surgeon at Fort Halleck, Nevada, relieving Acting Assistant Surgeon Loven N. Clark, United States Army.—*S. O. 113, Department of California*, November 30, 1885.

VICKERY, R. S., *Major and Surgeon.*—Relieved from the assignment as Acting Medical Director, Department of Colorado, to date, the 16th instant.—*S. O. 200, Department of Colorado*, November 23, 1885.

BIRMINGHAM, H. P., *First Lieutenant and Assistant Surgeon.*—Ordered for duty at Camp Grant, Riverside Park, New York City.—*S. O. 256, Department of the East*, December 4, 1885.

BUSHNELL, GEO. E., *First Lieutenant and Assistant Surgeon.*—Ordered for duty as Post Surgeon, Fort Preble, Maine.—*S. O. 256, Department of the East*, December 4, 1885.

WILSON, WM. J., *Captain and Assistant Surgeon.*—Ordered for duty as Post Surgeon, Plattsburg Barracks, New York.—*S. O. 256, Department of the East*, December 4, 1885.

APPEL, D. M., *Captain and Assistant Surgeon.*—Ordered for duty at Jackson Barracks, La.—*S. O. 256, Department of the East*, December 4, 1885.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING DECEMBER 5, 1885.

AULICK, HAMPTON, *Surgeon.*—Ordered to "Alliance" as relief of Surgeon G. P. Bradley.

BRADLEY, GEO. P., *Surgeon.*—Ordered to Naval Hospital, Philadelphia.

SHAFER, JOSEPH, *Assistant Surgeon.*—Detached from Naval Hospital, Philadelphia, and ordered to "Minnesota."

GAINES, J. H., *Passed Assistant Surgeon.*—Detached from Naval Hospital, Washington, and ordered to the "Dolphin."

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING DECEMBER 5, 1885.

WYMAN, WALTER, *Surgeon.*—Granted leave to attend meeting of American Public Health Association, December 3, 1885.

BENSON, J. A., *Passed Assistant Surgeon.*—Granted leave of absence for fifteen days, November 28, 1885.

ARMSTRONG, S. T., *Passed Assistant Surgeon.*—Granted leave of absence for eight days, November 30, 1885.

WASDIN, EUGENE, *Assistant Surgeon.*—Granted leave of absence for thirty days, November 28, 1885.

WATKINS, R. B., *Assistant Surgeon.*—To proceed to Galveston, Texas, for temporary duty, November 30, 1885.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLVII. SATURDAY, DECEMBER 19, 1885. No. 25.

ORIGINAL ARTICLES.

MARION COUNTY, FLORIDA: AN IDEAL WINTER CLIMATE.

BY GEO. TROUP MAXWELL, M.D.,
OF OCALA, FLA.,
PRESIDENT OF THE MARION COUNTY (FLA.) MEDICAL SOCIETY.

THE considerate and humane, whether physicians or laymen, must feel a deep interest in the subject of a climatic sanitarium for invalids suffering with diseases of the respiratory organs, for, chiefly, two reasons:

1st. The appalling fatality of these diseases—the deaths from consumption alone being annually more than double the number from any other cause; and,

2d. The failure of the best directed and most skilful medical treatment to diminish the fearful mortality.

An appropriate inquiry, just here, is, does the result of change of climate offer sufficient encouragement to physicians and patients to warrant the former in advising and the latter in undertaking the inconvenience, labor, and expense involved in the experiment? If the results of the observations and experience of those who are in situations which enable them to draw correct conclusions, did not, as they certainly do, justify a positive affirmative reply, statistics would suggest such a response as appropriate.

No one can fail to discover the significance, or to appreciate the value of facts like these: "The mortality from consumption as compared with all other causes is, in Maine, 258 to 1000; Connecticut, 179; Pennsylvania, 142; South Carolina, 90; whilst in Florida it is only 58 to 1000." What explanation other than climatic influence can satisfactorily account for the fact, that, passing from our extreme Northern States, as we go southward there is a constant, rapidly descending ratio of mortality from pulmonary diseases?

Yet, striking as these figures are, they do not give full justice to Florida. Prof. Levis, of Philadelphia, says:

"The low mortality of Florida exists, notwithstanding the number of Northern invalids who seek too late its healthy air only to end their days and add to the normally very low death-rate. The best authority on the subject, Dr. Kenworthy, of Jacksonville, who has given much intelligent attention to climate in the cure of consumption, and to sanitary statistics in general, believes that the mortality from consumption among the permanent residents of Florida actually does not exceed 30 to 1000 from all causes."

Nor are the results of a comparison of mortality statistics so favorable to Florida confined to inquiry into the proportion of death in the Atlantic States. From the instructive pamphlet of Prof. Coomes, of Louisville, I take the following: In Minnesota the deaths from consumption are as 1 to 7.6, from all other causes; California, 1 to 7.2; Texas, 1.16; Louisiana, 1 to 10; Arkansas and Alabama, each, 1 to 14.2; Georgia, 1 to 15.6; Mississippi, 1 to 13.2; and in Florida, 1 to 17.8." I learned, during a recent visit there, from an intelligent physician located in the blue grass region of Kentucky, that in that section, so favored of God in other respects, the ratio of deaths from consumption is as 1 to 6 from all other causes.

These imposing facts, established by cold, unimpassioned figures, were not manufactured by persons who may be suspected of being influenced by personal or pecuniary interest in Florida. They are derived from the National Census and were arranged by non-residents.

There is, I believe, universal agreement among writers on the subject, that *equability of temperature, comparative dryness of air and soil, and purity of atmosphere*, are essential elements of a winter climate for invalids suffering from diseases of the respiratory organs. There is not such entire accord upon the question of *range* of temperature.

Common sense, observation, and experience unite in declaring that, for a large majority of such invalids, the temperature should be such as to warrant and invite them to be and remain indefinitely in the open air without discomfort, and to permit its free entrance into their apartments day and night. It is simply impossible to overestimate the hygienic effect of *living*, as it were, out of doors, breathing pure, fresh air, and basking in the genial light of the sun. An artificial climate with the elements of warmth and dryness, may be manufactured in every Northern home; but there is no substitute for the God-given pure air and sunlight which invalids can enjoy in Florida almost every day in winter.

Consumptives, as a rule, suffer from defective digestion and assimilation. Nutrition is, therefore, imperfect, and, as a consequence, the vital powers are depressed. The heat-generating function, especially, except as the result of too rapid destructive metamorphosis, is abnormally feeble. Such invalids are exceedingly sensitive to sudden alternations of temperature, and to changes in the hygrometric state of the atmosphere. A sudden fall of temperature, or a gust of moisture-laden wind, chills and blights them instantly. Can there be anything more unphilosophical, not to say cruel, than to send such patients to localities where the mercury often falls, in a few hours, from 30 to 60 degrees, and generally hovers in the neighborhood of zero; or to places where the conducting power of the air is rapidly increased by moisture-laden winds? In either case the strain upon the vital powers of an invalid is more than he can bear, and he sickens and dies; or lingers and languishes in the confined, impure atmosphere of a superheated chamber.

The tendency to rely upon concentrated foods in the treatment of disorders of the digestive organs, has grown with the experience of their beneficial effect; yet in this enlightened age we are gravely told that the truly scientific method of managing the derangements of another system of organs, is to reverse this important principle of treatment. The impaired stomach requires concentrated food, thus imposing less labor upon, and giving partial rest to, an enfeebled organ; but the diseased, and probably disorganized lung can better recover, say these philosophers, on attenuated air! Therefore, their patients are sent "upon a high mountain," where, because the air is rarefied and attenuated, a small amount of oxygen is inhaled with each inspiratory effort, and the feeble heart is stimulated, and the diseased lungs' movements are hurried, that the demand of the poorly nourished body for oxidized blood may be satisfied. Instead of the much needed *rest*, so essential to inflamed organs, there is overexertion to breathe, and, therefore, irritation and aggravation of an erstwhile manageable case.

Granting the truth of Prof. Levis's remark, that "the ideal winter climate for invalids, embracing perfectly all the requirements, and suited to the fancy and caprice of sufferers, may not be found," it is capable of demonstration, nevertheless, that Florida possesses the essentials in a higher degree than any country now known.

It is my purpose to show that there is a portion of Florida, hitherto unknown, which is better adapted for a winter resort for invalids, especially those afflicted with weak or diseased respiratory organs, than any of the popular resorts of this, or any other country. Indeed, even the less favored localities of Florida will compare favorably with the resorts in other States or countries.

Perhaps one of the most surprising facts developed by the study of comparative meteorology, in its bearing upon climates, is that it *proves Florida to have a moderately dry atmosphere.* According to Vivenot's classification, an atmosphere with a percentage of humidity between 56 and 70, is moderately dry. Jacksonville, notwithstanding its unfavorable location upon the St. Johns River, and near the Atlantic Ocean, has 68 per cent. of relative humidity in its atmosphere, which brings it within the range of a moderately dry climate; "and this," Prof. Coomes says, "is much more moist than most of the interior towns."

The following table compiled by Dr. Kenworthy from the Signal Service Reports, shows that Jacksonville, in the matter of dryness of air, compares favorably with the popular resorts in all parts of the world:

"The public and a large majority of medical men speak of Minnesota as possessing a dry and desiccating climate, and of Jacksonville as having a moist and

changeable one—'an atmosphere loaded with moisture.' But three stations in the former give a mean of 74.5, and Jacksonville 68.8, or 5.7 in favor of Jacksonville."

To the same author I am indebted for the subjoined table, showing a comparison of the amount of rainfall during the five months beginning with November, comment upon which is unnecessary.

To illustrate by comparison another of the important factors of climate—the question of temperature, I avail myself of Dr. Kenworthy's industry and research, and take the following table, exhibiting the mean temperature of resorts in all parts of the world during the five months commencing with November:

Temperature.

"It is evident," says Prof. Levis, "that in Europe and in this country mild and warm climates have of recent years grown in favor as health resorts," and Dr. Kenworthy declares that "the modern professional view that *a temperate, dry, and sunny clime* is best adapted to the treatment of a large proportion of pulmonary diseases, is one of the most valuable contributions that modern science has made in the treatment of such diseases." Such being the case, I ask the reader's careful consideration of the facts I have as concisely as possible presented, confident that they must lead the minds of all impartial inquirers to the conclusion that in Florida are to be found the elements of a *climatic sanitarium* in a higher degree than are to be found elsewhere.

But Florida is a large State, covering a great extent of territory, with, of course, varying topographical features, which, to a certain degree, exert a modifying influence upon the climate of different localities. "During a visit to Florida," says Prof. Coomes, "I was much impressed with its great advantages as a winter resort for persons suffering with pulmonary affections, and with the charming features of its climate and scenery. There is an impression with many who have never visited this peculiar portion of the continent, that it is a low, damp country, mostly covered with water, but the visitor finds instead lands as fair and dry as those of Kentucky. It is true, that certain localities are made up of lowlands, interspersed with small lakes, and sluggish rivers and creeks. The lands of Florida may be divided into what are known as high pine lands, high hammock lands, low pine lands, low hammock lands, and swamp lands. The last named three varieties are to be scrupulously avoided by consumptives. It is a well-known fact that there are unhealthy localities in almost every State of the Union, and Florida is not without them. These we would expect to find along the St. Johns River, and in marshy districts." The above statements and opinions of Dr. Coomes, are so true and sensible, that I quote them to adopt them as my own. He who does not realize that there are great differences in healthfulness, and suitableness to the requirements of invalids, in a State with such an extensive area and varying topographical conditions as Florida, is inexcusably ignorant.

It is quite forty years since, as a boy, I made my home in Florida. Fully three-fourths of that time I have been actively engaged in the study and practice of medicine—at Tallahasse, Key West, Fernandina, Jacksonville, and Ocala. It is my misfortune, or fault, if I have not an intelligent idea of the topography, diseases, and climate of the State. Upon the assumption, if you please, of knowledge derived from study, observation, and experience, I must, if possible, dissuade physicians from advising their patients and invalids to go to either coast, *but especially the Atlantic.* The current of cold water which, starting from the Arctic Ocean and passing through Davis's Strait, is forced by the gulf stream against the Atlantic shore of the North American Continent to the southern extremity of the peninsula of Florida, chills the moisture-laden east wind which prevails on that coast, and renders it blighting in its effect upon invalids. To a large class of cases—those with feeble digestive and aspirative powers, who consequently make heat slowly and imperfectly, the Atlantic coast is positively obnoxious.

On the other hand, excess of moisture in the atmosphere with an elevated temperature is hurtful,

Digitized by Google

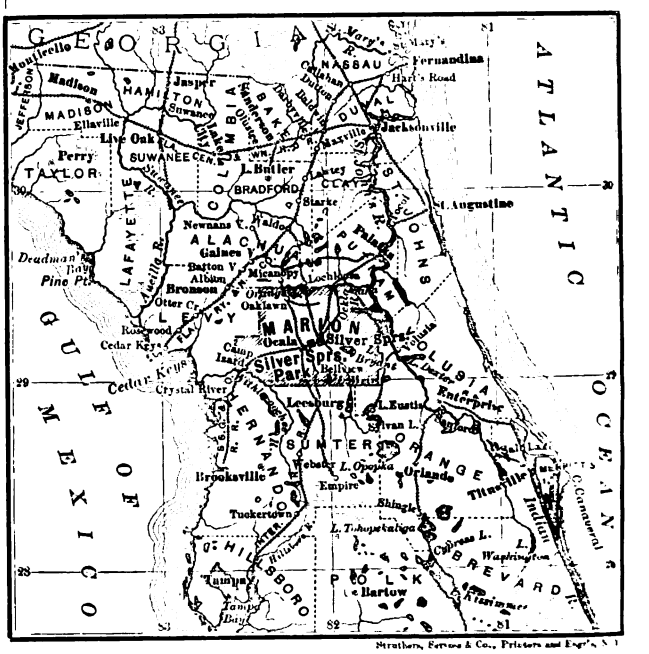
because evaporation is retarded, and perspiration, which in a moderately dry air would escape insensibly, accumulates upon the surface of the body as sweat, increasing discomfort and producing lassitude and debility. Besides, "a high thermal range, more especially if associated with a moist atmosphere, interferes with physical exercise, and in this respect is injurious. Hence, a climate like that of Nassau or Cuba is objectionable as a resort for pulmonary invalids" (Prof. Levis).

During my residence at Key West, as Surgeon of the Marine-Hospital, I personally experienced the force of Prof. Levis's objections to the climate of Nassau and Cuba, in the similar climate of the Key. Like the fabled vampire bat, that delightful but treacherous climate sucks the life-blood, whilst the genial trade wind fans and lulls into fancied, but false security. It is for those reasons that I would advise against sending patients, except the small class who require a warm, moist, sedative climate, to the Gulf coast, particularly to the southern portion of the peninsula.

A moderately warm, dry, and bracing climate, with plenty of sunshine, and few sudden and great atmospheric changes, is especially adapted to consumption in its earlier stages, to catarrh, chronic bronchitis, chronic pneumonia, rheumatism, renal diseases, and some cases of asthma. A warm, moist, and sedative climate is better adapted to cases of advanced phthisis.

Fifteen years ago (1870) whilst residing in Jacksonville, my attention was called to the peculiar excellence of the climate of the central portion of the peninsula by Prof. John T. Metcalfe, of New York, who, as a Lieutenant of the United States Army, on the staff of Gen. Jessup, acquired personal knowledge of the subject during the Seminole war; and he advised me to locate and establish a sanitarium there. At that time, and for more than ten years after, there being no railroads into the interior, access was difficult for the robust and impossible for the feeble. Bearing in mind the advice of Dr. Metcalfe, and having the impression made by him deepened into conviction by personal investigation, I came to Ocala four years ago, railroads having meanwhile reached this point. At that date hotel accommodations were inferior and insufficient, and for that reason I could not consistently with a sense of duty to patrons, and, therefore, would not persuade invalids to come to Ocala, notwithstanding the great advantages which nature, with liberal hand, has bestowed upon the locality. The difficulty no longer exists. There is abundant accommodation; there being four hotels—two of them substantially and elegantly constructed of brick, and first class in their appointments—and numerous comfortable boarding-houses. Now, I feel it to be my duty to call the attention of the profession and of invalids to the peculiar climatic advantages of Marion County.

By reference to the map, it will be seen that Marion County is situated in the centre of the peninsula, being about equidistant from the northern boundary of the State, and the southern habitable limit, and from the Atlantic and Gulf. Ocala, the county seat, is about fifty miles from the Atlantic Ocean and forty from the Gulf. It is, in fact, the "backbone" or watershed of that portion of the State. With a mean altitude of about 100 feet above the sea level, the surface of the county is beautifully undulating. This topographical feature insures thorough surface drainage, which contributes to healthfulness, and gives picturesqueness to the scenery which is pleasing to the eye. There is another fact in the topography of Marion County, the importance of which, in a hygienic point of view, cannot be exaggerated—that is, its remarkable exemption from surface water. In this regard it is unique, as a comparison with any other county of the peninsula will show. Look at the map of Florida, and it will



Strathern, Ferrero & Co., Printers and Engr's

be seen that, while every other county is dotted with ponds and lakes, from Orange Lake, on the north, to Lake Wier on the south, and from the Ocklawaha on the east, to the western boundary of the county—a distance each way of about forty miles—there is not here a body of water of sufficient size to be put on any map which has yet been published.

Whether this remarkable feature of the topography of Marion County is due to there being less precipitation, or rainfall, or to a pervious soil which permits percolation of water to great depths, or, as I believe, to both, the effect of making less evaporating surface, and, therefore, of causing a dry soil and atmosphere, results all the same, and that is the all-important element in its bearing upon health. Equable, warm temperature, and dryness, are, I repeat, the essentials in a health resort for invalids suffering with diseases common to higher latitudes; and tried by these tests, Marion County will be found to be fully up to the requirements.

Observations made by surgeons of the United States Army, during the Seminole war, at Fort King, now Ocala, show the following facts: Mean annual temperature is 70°, mean winter temperature 58.41°,

Digitized by Google

and for five months beginning with November, 60.55°.

The mean annual rainfall is 40 inches. Of this, 21.69 fall in the three months of summer, and for the five months beginning with November, the mean is 6.21 inches.

The late Dr. Forry, surgeon of the United States Army, distinguished as a physician and in natural science, says: "Whilst on the northern lakes, the annual ratio of fair days is 117, on the coast of Florida it is 250, and at Fort King (now Ocala) it is 309." Can any array of statistics be more impressive? Dr. Baldwin, as the result of twenty-five years' observation, says: "For the whole year there are 235 clear days at Jacksonville," which gives to Ocala 74 more clear days than Jacksonville. "I cannot refrain," says Prof. Coomes, "from mentioning the fact that I am frequently told by men who ought to know better, that the vicinity of Ocala is a low, wet, and unhealthy place. I visited the town, and I can see nothing more about the place to make it unhealthy than I can about Palatka, St. Augustine, Gainesville, and a dozen other places; and yet, in the face of scientific demonstration, which gives a verdict contrary to theirs, these same men continue to make assertions, which, at least, must soon fall through for the want of support, but, I fear, not until they have done incalculable harm to thousands. If 309 days out of 365 are fair, how can it be possible for the climate to be wet? Such is the condition of Ocala."

"Malaria is the subject which enters into the description of all southern climes, and we unhesitatingly assert that Florida has been misrepresented in this respect. I speak from personal observation, experience, and extended inquiry, and I assert that the opinion entertained with regard to the prevalence of malaria during the cold months, is unfounded." I have quoted the foregoing statements of Dr. Kenworthy to reinforce them, if it were necessary, by my own knowledge derived from observation and experience, running through quite forty years of intimate acquaintance with the sanitary history of Florida. From November to June, inclusive, a visitor is as safe from attacks of malarial disease in Florida as in the Adirondacks.

In the centre of the county is the county seat, the beautiful city of Ocala, containing about 2500 inhabitants, and growing with marvellous rapidity. Since railroad facilities for transportation were furnished about four years ago, the population and business of the place have increased over 300 per cent.

Ocala is 173 feet above the level of the sea, 100 feet above Palatka, 150 above Jacksonville, and 160 above Fernandina and St. Augustine. Added to great natural advantages for health, business, and pleasure, she has as attractions, the largest and finest brick hotels in the State, with all that can be desired in the way of social, educational, and religious privileges. Ocala is surrounded by the richest land and the finest orange groves and vegetable farms in the State, while of easy access by a short drive and by railroad, is the world-renowned curiosity Silver Spring, whose crystal waters—through which a nickel can be distinctly seen at the depth of 65 feet—and weird surroundings, have long been celebrated.

TWO CASES OF UNILATERAL ŒDEMA OF THE LARYNX, DUE TO TRAUMATISM (BONE-SWALLOWING).

BY SOLOMON SOLIS-COHEN, A.M., M.D.,
CHIEF OF CLINIC, OUTPATIENT MEDICAL DEPARTMENT, JEFFERSON MEDICAL COLLEGE HOSPITAL.

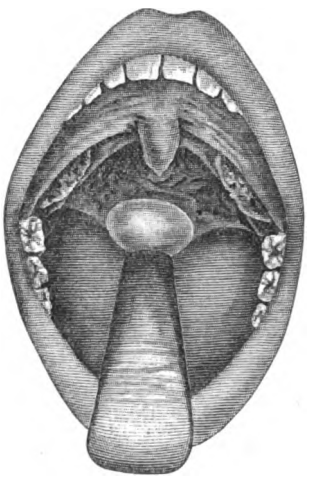
THE following cases seem to be of sufficient interest to warrant the publication of a brief report:

CASE I.—Sallie ——, a negress, aged 17 years, came to the throat department of the Philadelphia Polyclinic complaining of great distress in breathing, which had increased steadily since the preceding evening. A fish bone had "stuck in her throat" at supper, but she had succeeded in dislodging it with the finger, and believed that it had then passed into the stomach without further accident. She had no idea of the size of the bone, and did not know the name of the fish she had been eating. Dyspnœa developed soon after the accident, and at times severe paroxysms of suffocation occurred. There was not much pain.

At the time the patient applied for relief, some eighteen or twenty hours after the first symptoms were manifested, she was evidently in great distress. The voice was rough, hoarse, and muffled. Respiration was stridulous and labored. The lips were bluish, the countenance ashy and anxious.

On inspection of the throat, the œdematous epiglottis was seen projecting upward behind the tongue, as a roundish, tense, glistening, yellowish, bladder-like tumor (Fig. 1).

FIG. 1.



Laryngoscopic examination showed œdema of the epiglottic crest, with marked œdema of the arytenoepiglottic fold and arytenoid eminence of the left side, and very slight œdema of the right arytenoid eminence.

The epiglottis, and later the tumid structures on the left side of the larynx, were scarified by means of a curved bistoury wrapped with cotton to within about two lines of the point; and bleeding, which was rather scant, was encouraged by draughts of tepid water. A brisk hydragogue cathartic was ad-

Digitized by Google

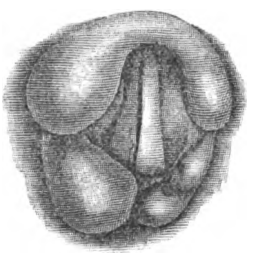
ministered. Iced cloths were ordered to be applied to the neck, and the patient was directed to allow small pieces of ice to melt in the mouth at frequent intervals.

The patient returned next day feeling much easier, though some œdematous tumefaction of the left arytenoid eminence persisted. No trace of the foreign body could be seen. Scarification was repeated, and the purgative medicine and cold applications were continued. The patient made two more visits to the clinic, and then disappeared from observation. As all local troubles, with the exception of congestion of the larynx, had also disappeared, it is to be presumed that she made a good recovery.

CASE II.—Daniel McC——, aged 42 years, laborer, attempted to gnaw the meat from a leg (?) of pork, and thinks that he got a small sliver of bone in his throat. At all events, he was seized soon afterwards with a violent pain in the throat, and a severe paroxysm of coughing. Towards evening, difficulty in breathing developed, and progressively increased. The right side of the neck became swollen, and tender to the touch. He was unable to sleep, and two or three times during the night, thought that he would choke to death. By morning, he had begun to feel easier, but still experienced difficulty in breathing, with paroxysms of intense dyspnœa. He applied to a physician in his neighborhood, who referred him to me.

I saw him about twenty-two hours after the probable date of the bone-swallowing. The voice was slightly hoarse, but distinct. There was very little distress in breathing. The right side of the neck was tender upon pressure, and slightly swollen from the margin of the thyroid cartilage to a little beyond the angle of the jaw. Laryngoscopic examination revealed the picture shown in the accompanying sketch

FIG. 2.



(Fig. 2).[1] The crest of the epiglottis, especially on the right side, the right aryteno-epiglottic fold, and right arytenoid eminence were moderately œdematous. The right ventricular wall, so far as could be seen, and the corresponding vocal band, both of which were in shadow from the overhanging tumefied epiglottis and ary-epiglottic fold, were of a deep red color. The left side of the epiglottic crest was slightly œdematous, but the other structures upon that side seemed perfectly normal. Careful search was made for the foreign body, but it could not be seen either in the larynx or surrounding spaces or tissues.

Scarification of the right side of the epiglottis, and afterwards of the right ary-epiglottic fold was practised by means of a laryngeal knife, unguarded; and a hasty movement of the patient on the second withdrawal of the instrument caused a superficial wound of the base of the tongue. Bleeding was quite free upon both occasions; the blood being dark and grumous. Cold applications and free purgation were advised, as in Case I.

The patient returned on the following evening, reporting that he had passed a quiet night and a comfortable day. The external swelling had subsided. The larynx was normal, save for a slight congestion of the right side. No trace of the foreign body could be discovered.

Remarks.—Although cases of unilateral œdema of the larynx are not often reported, it is believed that such instances as the foregoing, cannot be exceedingly rare; the two cases in question having been observed by the writer within the space of six months. The fact that the dyspnœa in both cases, and especially in Case II., was out of all proportion to the extent of the œdema, gives additional confirmation to the view[1] that spasm of the constrictor muscles of the larynx forms an integral part of the pathology of œdema of that organ. The cause of the œdema in both instances was probably a wound of the epiglottis, exactly comparable, as remarked by Charazac in his recent admirable and exhaustive thesis,[2] to the accidental experimental results of Bichat,[3] who, in the course of physiological investigations, produced œdema of the larynx by wounding the epiglottis of a dog.

HOSPITAL NOTES.

DISPENSARY FOR NERVOUS DISEASES, BALTIMORE.

Service of JOHN VAN BIBBER, M.D.

CLINICAL NOTES.

Brain Lesions in Adults following Parotiditis.

These cases occurred in private practice, but as they are comparatively rare, and as this class of cases would not probably apply to the dispensary for treatment, I give a short account of them as an interesting group, in connection with the previously reported cases of brain lesion consequent upon acute and serious abdominal symptoms.

Three Cases of Metastatic Insanity following Parotiditis.

J. F., age 20, in January had an attack of mumps, well marked, and from which he apparently recovered. Before, however, the swelling had entirely subsided, he was obliged to go out in bad weather. On returning

[1] I am indebted to Dr. M. J. Stern, of this city, for the transformation of my outline sketches to the graphic illustrations herewith presented.

Digitized by Google

home, on same evening, had pain and swelling in his testicles. For two days these symptoms increased, and on the third morning from date of exposure he developed decided delirium and hallucinations. Countenance suffused, pupils contracted, and sense of fulness in head. Temperature 102°. Under use of febrifuge and diuretic treatment, and hot applications to abdomen and parotid glands, the testicles slowly returned to normal size, but hallucinations and delirium continued with more or less violence for two weeks, when they began slowly to abate, and at end of a month the patient was entirely well.

M. W., aged 22, member of a religious institution, where her duty was to attend to the door. In March had an attack of parotiditis, and after going through the usual course of the disease, and the glands having been reduced in size, she returned to her occupation. After two days, she came back to the Infirmary complaining of headache and nausea. Under the circumstances it was impossible to determine whether the mammæ were swollen or painful, for delirium quickly developed and was marked and active. Face flushed, and temperature 101.05°. Hallucinations were incessant, and restlessness so great that it was very difficult to control her. Diuretic and febrifuge treatment was ordered, and hot applications to parotid glands and abdomen. Patient had a silly and vacant expression, laughed incessantly, and speech was incoherent. Insomnia and delirium continued for two weeks, during which time she took large quantities of potas. brom. After this period she gradually became quieter and more amenable to treatment, but the hallucinations continued for more than six weeks, when she began slowly to regain her mind, and at the end of two months had entirely recovered.

P. T., farmer, aged 26. In February, had an attack of mumps, and before the glands had entirely subsided he caught cold, and was much astonished the day following to find his testicles swollen and painful. Under treatment of the family physician this trouble was relieved; but while he was still confined to the house he became impressed with the idea that he could never get well, that he could not eat, etc. He soon developed a typical form of hypochondriacal melancholia, and was in this condition when I first saw him in May. He continued in this condition until the end of July, at which time he had entirely recovered and was able to resume his occupation.

Each of these patients showed a distinct type of insanity, proceeding from the same cause; and if such serious results are to be looked for as the possible sequel of parotiditis in the adult, the disease must be more carefully treated until recovery is completely established.

MEDICAL PROGRESS.

A COMPARATIVE STUDY OF THE EFFECTS OF DIFFERENT ALCOHOLIC BEVERAGES.—M. LANCEREAUX has presented before the Académie de Médecine (session of Nov. 17, 1885) an analysis of the "alcoholic" cases at present in the hospitals, and shows that they come chiefly from the departments in which wine is not produced. He would arrange the alcoholic beverages in the following order of increasing toxicity: cider, beer, wine, the liquors derived from grain, from potatoes, and from beet root.

He proposes the national adoption of the following measures:

1. Absolute liberty in the sale of cider, beer, and wine, on condition that they are of good quality and unadulterated.

2. Government supervision of the manufacture of spirits of all kinds, and the granting of prizes for methods of diminishing their ill-effects.

3. The imposition of the highest practicable tax upon spirituous drinks, and an insistence upon both good moral character and a severe license in the case of liquor dealers.

4. The punishment of those found in a state of intoxication, and the establishment of refuges for those who cannot refrain from the abuse of strong liquors.

BLISTERING BY CANTHARIDES.—DR. SQUIBB refers to the frequent apparent inefficiency of cantharidal preparations, especially in the summer, and advises, when any difficulty arises in this regard, that the skin should be carefully washed either with vinegar or with dilute acetic acid before applying the blister.—*Ephemeris*, November, 1885.

NEPHROTOMY AND NEPHROLITHOTOMY.—MR. BENNETT MAY presented before the Birmingham and Midland Counties Branch the notes of three cases of nephrotomy and nephrolithotomy, of which the following is a short abstract: Case 1. Youth, aged 20; symptoms well marked; duration, fourteen years; incision made into kidney; calculi removed; free hemorrhage, which stopped only on firm plugging; subsequent perinephritic suppuration; thrombosis; death from pyæmia in three weeks. Case 2. Male, aged 35; symptoms of ten years' duration; small stone detected in kidney by acupuncture; operation; stone removed through very small incision; another larger stone afterwards removed; rapid recovery; now able to do hard work; patient shown. Case 3. Female, aged 23; symptoms well marked; eighteen months' duration; six weeks before passed mulberry calculus *per urethram;* relief; subsequent relapse; operation; failure of palpation and acupuncture to discover stone; no stone found; rapid recovery, with relief of symptoms.

MR. LLOYD showed a calculus which he had removed eight days before from the kidney of a man, aged 20, through a lumbar incision. Symptoms had been present for four years, and had quite incapacitated the man from work. The patient had so far recovered as to be out of all danger. The urine was acid, normal in quantity, and contained only a few pus- and blood-corpuscles.—*British Medical Journal*, Oct. 31, 1885.

REMOVAL OF A LIPOMA OF THE MESENTERY, WEIGHING FIFTY-SEVEN POUNDS.—In September last, TERILLON presented before the Académie de Médecine a lipoma weighing fifty-seven pounds removed from a laborer aged thirty-seven. The tumor had been gradually increasing in size for the preceding three years. A large abdominal opening revealed a lobulated lipoma of the mesentery situated in front of the vertebral column and of the right iliac fossa. It was removed in one

Digitized by Google

piece after a difficult decortication. The cut peritoneum was resected; eight catgut ligatures prevented hemorrhage, and twenty sutures of silver wire were required to close the abdominal wound. Two weeks after the operation the patient was fairly recovered, except for a persistent diarrhœa which prevented perfect alimentation.—*Bulletin Gén. de Thérap.*, 1885, No. 8.

CONGENITAL SYPHILIS.—NEUMANN, in an elaborate bibliographical and clinical study of congenital syphilis, reaches the following conclusions from the facts presented:

1. The usual opinions regarding the effects of syphilis of the father are confirmed.

2. Recent syphilis of the mother, at the time of conception, induces disease of marked intensity in the product of conception.

3. The longer the duration of the syphilis of the mother the less is the danger for the progeny, and the more favorable is the action of specific treatment.

4. Tertiary syphilis, on the part of the mother, has no direct influence upon the power of conception, impairment of this function existing only as a result of gummata of the uterus or ovaries.

5. Syphilis acquired after conception is rarely shared by the product; immunity from such transmission, however, does not exist. The period of pregnancy in which syphilis is acquired does not appear to affect the frequency of transmission to offspring. Syphilis acquired after conception is more dangerous for the subsequent offspring than for the fœtus at that time *in utero*.

6. The possibility, but not the certainty of transmission of syphilis from the fœtus to the mother (*choc en retour*) is admitted. No data have been obtained as to the month of pregnancy in which this occurs.

7. Hereditary syphilis is highly contagious for every one except the mother.

8. No absolute laws of inheritance of syphilis can yet be formulated.—*Wien. med. Jahrb.*, 1885, Hefte ii., iii., p. 286.

TWO SUCCESSFUL CASES OF CHOLECYSTOTOMY.—After reference to the paper by Lawson Tait on the surgical treatment of gall-stones, and to the thirty-five cases of cholecystotomy recorded by Drs. Musser and Keen, MR. A. W. MAYO ROBSON presented before the Clinical Society of London a report of two successful cases of cholecystotomy.

In the first case, Mr. Robson was consulted in June, 1884, by Mrs. B., aged thirty-three, on account of a tumor of the size of a hen's egg; it caused dragging pain and uneasiness, but there had never been any jaundice. It was then diagnosed as a distended gall-bladder, but consent to operate was not obtained until June 21, 1885, when, the tumor having greatly increased in size, with augmentation of the discomfort, cholecystotomy was performed, and eight facetted gall-stones were removed from the cystic duct. They varied from the size of a pea to that of a large bean, and were of a dark brown color. The gall-bladder contained nearly half a pint of clear watery fluid, which was removed by an aspirator before the cyst was opened. Peritoneum was then sutured to peritoneum, and mucous membrane to skin, and the rest of the wound was closed by catgut sutures, a drainage-tube being inserted into the gall-bladder. Recovery was uninterrupted, union occurring by first intention, and the patient being able to go for a drive on the seventeenth day. A minute fistula remained in September, just capable of admitting a small probe. It discharged a little thin mucus, but gave no inconvenience. The patient was feeling well in every respect, having gained in strength and weight. The second case was that of a German governess, aged twenty-two, who was admitted into the Leeds Infirmary, under the care of Dr. Churton, in February, 1885. There were vomiting after all food, a history of prolonged constipation, and a tumor in the position of the hepatic flexure of the colon, the size of which was unaffected by many large enemata; the vomiting continued. It being then suspected that the tumor was a distended gall-bladder, the patient was transferred to Mr. Robson, who performed cholecystotomy, removing numerous small white calculi, and eight ounces of clear fluid. The steps of the operation were exactly the same as in the first case, and in both the finger was passed inside the peritoneum, along the cystic duct, in order to be sure that no calculi were left to cause a block in the passage. After the operation, the vomiting absolutely ceased, and recovery was uninterrupted, the pulse and temperature being normal throughout, and the wound healing by first intention. The fistula discharged a clear mucous fluid for a time, but on September 15th had completely closed. It, however, reopened in October, and again discharged the same kind of fluid, the patient experiencing no discomfort or pain, and feeling absolutely well in every respect.—*Brit. Med. Journ.*, Oct. 31, 1885.

CUTANEOUS ANODYNE.—DR. R. G. GOUCH, in *The Virginia Medical Monthly*, recommends the following prescription as one of the best he has ever found as a lotion for itching cutaneous surfaces, whether the skin is broken or not. He has used it with invariable success, and it has now become a popular application with the local physicians:

℞.—Sodæ biborat.	. . . .	ʒj
Acid. carbol.	. . . .	gtt. xv.
Glycerin	. . . . .	ʒj.—M.

Sig. Apply as lotion with camel's-hair brush, or by dropping from bottle on the itching surfaces.—*Canadian Practitioner*, Dec. 1885.

THE DISINFECTION OF THE HANDS.—FORSTER, of Amsterdam, has made an experimental investigation of the comparative values of different methods of rendering sterile the bacterial dust which is always present on the hands. All the known disinfectants were used, and the so purified finger was dipped in sterilized neutral beef-juice peptone solution.

With one exception, the development in the culture media of fungi, in from twenty-four to sixty hours, was not prevented by the treatment of the finger. Even washing with two and a half per cent. carbolic acid solution was inefficacious. Corrosive sublimate solutions alone, of a strength of from half to one part in one thousand, were found to be of use; and the finger thus treated, when dipped in the most sensitive culture media induced therein no fungous growth.—*Centralb. f. Gynäk.*, Nov. 21, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, DECEMBER 19, 1885.

THE PRIMARY MUSCULAR ATROPHIES.

THE mutual relations of the various affections characterized by progressive atrophy of the muscles are very clearly set forth in communications by CHARCOT, in *Le Progrès Médical*, No. 10, 1885, and by his pupils MARIE and GUINON, in *Revue de Médecine*, October, 1885. Two essentially distinct groups of cases are recognized, first, the spinal myopathies, in which the lesion is in the cord; and second, the primary myopathies, in which the lesion is entirely muscular, and the central nervous system is unaffected. Of the former group there are two fundamental divisions, the *amyotrophic lateral sclerosis*, in which the lesion of the gray matter inducing the atrophy is secondary to various conditions, such as diffuse myelitis, tumors, and multiple sclerosis; and, the chronic myelitis of the anterior horns, *poliomyelitis anterior chronica*, which is known clinically as progressive muscular atrophy. The second group embraces at least three diseases, pseudo-hypertrophic paralysis, Erb's juvenile form of progressive muscular atrophy, and the hereditary infantile form of Duchenne; and a successful attempt is made to show that they are not separate affections, but merely different clinical forms of one and the same disease, for which the designation *myopathie progressive primitive*, is suggested.

In pseudo-hypertrophic paralysis, the enlargement of the muscles is spurious and the process is, in reality, an atrophic sclerosis, in which the increased size is due to connective tissue and fat. The lesion is entirely muscular, and Charcot protests against the assumption by some writers, at this period in the history of the disease, that the affection is of spinal origin. Duchenne observed that the hypertrophied muscles might finally become wasted, but atrophy of certain groups of muscles may coexist with pseudo-hypertrophy in others, or the disease, as in Goodridge's cases, may begin with wasting of the muscles of the shoulders and arms, and be followed by pseudo-hypertrophy of the calf muscles. Upon this feature of the disease authors have scarcely laid sufficient stress, but Marie and Guinon rightly deem it of great importance in studying its relations to other atrophies. The muscles of the shoulder-girdle and the biceps are most frequently involved in this primary atrophy. It is well known that the increase in volume of the muscle does not bear any special proportion to the loss of power; indeed, the functional weakness may precede, for some time, the pseudo-hypertrophy, or it may be the most striking characteristic, as Charcot has shown in a remarkable case with all the features of pseudo-hypertrophic paralysis without any augmentation or diminution in the volume of the muscles. A lad, aged eleven, presented the typical position in standing and in walking, and in behavior on raising himself from the recumbent posture, and yet the muscles appeared of normal size—neither atrophied nor hypertrophied.

The juvenile form of progressive muscular atrophy described by Erb is characterized by atrophy and feebleness of certain groups of muscles, particularly those of the shoulder-girdle, the upper arms, the pelvis, the thighs, and the back. It begins in infancy or adolescence, and progresses slowly with or without interruptions. The atrophy is often combined with true or false hypertrophy of certain muscles; there are no fibrillar tremors, and the affected muscles do not present the reaction of degeneration. The muscles of the forearms, with the exception of the long supinators and those of the hands, generally remain unaffected. The leg muscles also, with the exception of the tibiales antici and peronei, are usually spared. This form has hitherto been confounded with the progressive muscular atrophy of special origin, due to chronic poliomyelitis, but it is distinguished from it by the mode of invasion, the age affected —usually under twenty—the absence of fibrillar tremors, the electrical condition of the muscles, and, finally, the absence of lesions in the cord. Erb regards the affection as a myopathy, and its immediate relations are evidently with pseudo-hypertrophic paralysis, which it resembles also in attacking several members of the same family.

In 1865 Duchenne described a hereditary infantile form of progressive muscular atrophy, which was characterized by its onset at an early age, and by the commencement of the atrophy in the facial muscles. He had seen as many as twenty cases, but apparently little attention has been paid to it, and some authors have doubted its existence as a distinct form.

Digitized by Google

The clinical features, as drawn by Charcot and his pupils, are briefly as follows: The affection often begins in infancy, but it may not come on until adolescence or even until middle or advanced age; it is very often hereditary; the face muscles are first involved, particularly the orbicularis oris, and there is a peculiar expression of the countenance; whistling is impossible, and the articulation of labials is difficult; the eyes cannot be completely closed, and the eyebrows cannot be raised. Subsequently, other muscles become involved, particularly those of the shoulder-girdle—except the deltoid—and arm, the long supinators of the forearm, and in the lower extremities the muscles of the buttocks, thighs, and of the antero-external aspect of the leg. The muscles of the hands and fingers are spared. Fibrillar tremors are not observed, and there is no reaction of degeneration. The distribution of the atrophy is almost identical with Erb's form, except that the trouble begins in the face. That this is a myopathic and not a spinal affection, is conclusively shown by a recent autopsy of a typical case, in which the cord and peripheral nerves were found to be normal.

Charcot also holds that this form is also closely related to pseudo-hypertrophic paralysis, and quotes in support an observation of Zimmerlin, in which two children of a family presented the juvenile form of Erb, while, in a third, the affection began with atrophy of the facial muscles, and there was pseudo-hypertrophy of the muscles of the legs.

With Charcot, then, we may regard these affections as different forms of one and the same disease —a primitive progressive myopathy, the lesion being an interstitial myositis with variable production of adipose tissue and occasionally hypertrophy of individual muscle fibres. Clinically they present certain differences by which the varieties may be recognized, but there are intermediate forms which serve to show the essential unity of the disease. All three are hereditary maladies, or rather family diseases, occurring in several members of the same family.

It seems probable also that Thomsen's disease is another myopathic affection closely related to hypertrophic paralysis. This curious hereditary or family malady is characterized by a remarkable stiffness or spasm in the muscles on first attempting to perform voluntary movements. Vigouroux has recorded a case with pseudo-hypertrophy of the muscles, and Erb has recently described definite changes in the muscles in two cases under his care.

COLECTOMY.

IN the *Allgemeine Wiener med. Zeitung*, Nos. 41, 42, and 43, 1885, may be found an account of a unique case of cicatricial stricture of the ileocœcal valve, in which CARL MAYDL afforded temporary relief by enterotomy, and subsequently effected a radical cure by excision of the coarctation.

The patient, a woman, twenty-four years of age, had suffered with symptoms of ileus for two weeks, and a nodular, tolerably firm, and rather freely mobile tumor, as large as the first, was detected just below the right kidney, when the subject was placed in the knee and elbow position. Obstruction at the point of junction of the ileum with the cæcum was diagnosticated, but its true nature could not be determined. On the 31st of January, 1884, the belly was opened in the anterior axillary line, and an artificial anus was established by stitching the ileum to the abdominal wall. The patient recovered and gained flesh and strength, but being dissatisfied with her condition, Maydl, on the 7th of March, 1885, removed the portion of the small intestine which included the fecal fistula, as well as the part of the cœcum which was strictured, and reunited the ileum to the large intestine by many points of the Czerny-Lembert suture. At the expiration of four weeks the recovery was complete, and the woman now enjoys excellent health.

Resection of the intestine in any portion of its extent for fibrous stricture has, so far as we know, been performed in only three instances. In the *Centralblatt für Chirurgie*, 1881, Koeberlé records a case of multiple coarctation, in which he successfully removed more than six feet of the small intestine; and Novaro has reported in the *Giornale dell' Academia di Med. di Torino*, 1881, a case in which he extirpated nearly four inches of the ileum for a single stricture, with recovery. The third case is that of Maydl, and it is the only one in which a portion of the large intestine has been excised for a benign stricture.

In connection with this case it is interesting to note that the large intestine has been extirpated, sutured, and returned into the belly in at least 25 additional instances. Of the 26, 12 recovered and 14 died. For carcinoma, colectomy has been done 20 times; and of these, 9 were successful, and 11 fatal. For gangrenous hernia, 2 cases show 2 deaths. For prolapse of the sigmoid flexure through an artificial anus, Czerny had 1 recovery; while for prolapse through the normal anus, the patient of Auffret died, while that of Mikulicz recovered.

As we have seen, colectomy with enterorrhaphy and suture of the bowel for carcinoma has been attended with a mortality of 55 per cent., and, for obvious reasons, it would appear as if the operation ought to be more dangerous than mere excision of the neoplasm, with the formation of an artificial anus. Such, however, is not the fact, since of 8 examples of the latter operation of which we have notes, 5, or 62.5 per cent., perished. Hence, so far as the limited number of operations entitles us to frame an opinion, the

Digitized by Google

former, although the more tedious, and requiring greater attention to details, is the preferable procedure. So far, however, as the final result is concerned, there is little to be said in favor of either operation, as we are not aware of a single instance of permanent recovery, recurrence of the disease having been the invariable rule in all the cases that we have able to follow.

NATIONAL SANITARY LEGISLATION.

WHILE it seems to be the almost universal opinion among sanitarians, and especially among sanitary officials, that it is highly desirable that the general Government should do something more than it is now doing for the protection of the public health, and, in particular, that Congress should provide for some kind of a department, or board, or bureau, to look after the interests of the public health, it must be confessed that there is not enough unanimity as to the form which such legislation should take, to make us feel very hopeful as to the probability of any action by Congress at the present session.

At the Conference of State Boards of Health, held at Washington last week, the subject of federal legislation on sanitary matters received a good deal of consideration, but it was evident that the difficulties in the way seemed very formidable to those most familiar with the matter; and that while there was substantial agreement as to many of the things which a National Health Department should have charge of, or do, there was very great divergence of opinion as to the particular form of such organization which it would be expedient to urge upon Congress.

The great majority were of the opinion that it is useless to attempt to rehabilitate the present National Board of Health. Some favored the idea of a National Board to be composed of representatives from State Boards of Health, etc., as embodied in the bill presented to Congress by the last Conference. Others preferred the creation of a Bureau with a Commissioner of Health—analogous to the Bureau of Education or of Agriculture, and to be attached to either the State Department or the Department of the Interior. One difficulty in the organization of such a Bureau is that its work includes matters pertaining to the duties of three different Departments, and, therefore, harmonious action between these Departments is necessary to insure success. For example, the business of collecting information as to the sanitary condition of foreign ports, and of vessels sailing from them to the United States, should be done by officers of the Department of State. Matters pertaining to the collection of vital statistics in this country, to local epidemics, and to biological and chemical investigations, pertain more especially to the Department of the Interior, while matters pertaining to quarantine at United States ports, belong to the business of the Treasury Department.

It will be seen that the view which one takes as to what should be the predominant function of the National Health Bureau, will greatly influence his opinion as to what particular department should control and be responsible for it. It seems probable that it would be easier to obtain from Congress the necessary legislation for the creation of a Health Bureau under the Department of the Interior, than for the rehabilitation of the National Board or the creation of a new board, and that it is best to concentrate effort in this direction. It appears, moreover, that the less such a Bureau has to do with quarantine operations at United States ports the better, at all events for the present.

The field of work for such a Bureau is certainly wide enough without the quarantine business. Unfortunately, there are a number of persons whose voices are influential in this matter who think that quarantine work should be the chief business of such a Bureau, and that, in fact, the Bureau should not be created unless it is to assume these duties. It is this feeling, taken in conjunction with the opposition of the present National Board to any measure looking to its supersession, and the opposition of the Treasury Department and the Marine-Hospital Service to anything which might deprive it of its patronage, that the chief obstacles to National legislation on public health matters arise. We do not think that these obstacles will prove to be very formidable when they are once fairly recognized and understood by the people.

NERVE SUTURE, WITH IMMEDIATE RESTORATION OF FUNCTION.

ONE of the most remarkable results of the suture of a nerve ever reported is given by SURMAY, in the *Archives Gèn. de Médecine*, for Oct. 1885. The case was that of a man who had received a cut above the wrist, resulting in abolition of the function of the median nerve. For some time no attempt had been made to correct the defect. Then electricity was tried without result. Six months after the accident, Surmay resected about three-quarters of an inch of the nerve, and joined the cut ends with a fine carbolized catgut thread, which had been ingeniously inserted before the intermediate portion was cut out. The function of the nerve was reëstablished within twenty-four hours! The parts which had before been affected—the second phalanx of the thumb and the two terminal phalanges of the index and middle fingers—were found to have wholly recovered their general and tactile sensibility; while the sensibility to pain and temperature had returned in the thumb and in the upper half of the phalanges of the other fingers

Digitized by Google

involved. Complete restoration followed after several months.

This remarkable case furnishes a strong support to operative interference in other cases than those in which loss of function results from traumatic division of a nerve; for in this one the nerve was not found divided, but the part under the wound was occupied by an enlargement which was formed by pure hypertrophy of the neurilemma. It is always surprising that the cicatricial changes which must take place in, or immediately adjacent to, a resected nerve, should have so little effect in disturbing the result of the operation. In the case mentioned, it seems to have had some disturbing influence, although this passed off with time. Further, this case is interesting as raising questions in physiology which will bear close study, namely, as to the reinstatement of one part of the function of a nerve while another remains in abeyance, as well as in regard to the relation of the different forms of sensation, which are commonly divided into: common sensation or sensation of pain, and the tactile sense, which includes appreciation of changes in temperature. As Surmay's case seems to have been studied with great care, and to present many of the conditions of scientific accuracy, it may contribute materially to our knowledge of the physiology of the nerves.

SOCIETY PROCEEDINGS.

THE AMERICAN PUBLIC HEALTH ASSOCIATION.

Thirteenth Annual Meeting, held at Washington, D. C., December 8, 9, 10, and 11, 1885.

(Specially reported for THE MEDICAL NEWS.)

TUESDAY, DECEMBER 8TH.—FIRST DAY.

THE Thirteenth Annual Session was called to order by THE PRESIDENT, DR. J. E. REEVES, of Wheeling, at 10 o'clock.

THE TREASURER'S REPORT.

DR. J. BERRIEN LINDSLEY read his report, showing expenditures amounting to $2232, and a balance on hand of $1105. The report was accepted.

DR. ROHÉ presented the

REPORTS OF THE COMMITTEE ON DISINFECTANTS,

and asked the Executive Committee to fix an hour on Thursday, when its discussion can take place.

DR. EZRA M. HUNT, Secretary of the State Board of Health of New Jersey, then read a paper on

SANITARY AND STATISTICAL NOMENCLATURE,

in which he discussed the various terms now used in sanitary, statistical, and parasitical nomenclature.

DR. JOHN S. BILLINGS, U. S. A., then presented a paper on

FORMS OF TABLES OF VITAL STATISTICS.

After discussing different forms now in use, he proceeded to explain what should be included in or rejected from such tables. Vital statistics are furnished to the public through the press, and he urged that it is the wisest course for the health officer to furnish full and accurate reports of prevailing sickness and deaths every week, so far as he had the reliable data for so doing, thus avoiding the responsibility of concealment. He said that there are several sources of information with regard to the amount and character of disease prevailing in a city, of which the health officer can avail himself, and which are too much neglected. There are the public dispensaries and other similar institutions, including the city physicians to the poor, the prisons, reformatories, and asylums, and the public schools. From all of such institutions supported by public funds, he should be able to obtain reports showing the amount and character of the diseases coming under their notice. Attention was called to the importance of using graphic representations of the results of studies of vital statistics, to be given in the form of diagrams and shaded maps. He exhibited large diagrams of a proposed form of tables.

DR. HENRY B. BAKER, Secretary of the State Board of Health, Lansing, Mich., read a paper on

THE RELATION OF RAINFALL AND WATER SUPPLY TO CHOLERA,

in which he showed that cholera always increased during the dry season, and decreased after an abundant fall of rain. He presented tables in support of his statements.

DR. D. E. SALMON, D.V.S., of Washington, D. C., then read a paper on

THE VIRUS OF HOG CHOLERA,

in which he stated that during the present year the ravages of hog cholera had been unusually severe, costing the country nearly $30,000,000. The disposition of the carcasses of animals which have died of this disease is a matter which affects the health of our people. Sometimes, carcasses are left to putrefy, or to be preyed upon by carrion birds, or animals; and sometimes they are thrown into the ponds and streams which furnish our drinking water. Sometimes they are rendered into lard, and what becomes of this product is an interesting subject for speculation. Only exceptionally are they burned or buried. The study of the virus is of peculiar interest to us at this time, because of its bearing upon the general subject of contagion. The science which treats of this important class of phenomena is still in its infancy, but experiments are in progress which will undoubtedly result in decreasing the disease. He gave the results of a number of experiments in inoculation with Pasteur's virus, some of which were successful while others failed.

DR. HUNT inquired whether the investigation made by the Bureau of Animal Industry has lead to the conclusion arrived at by Klein,—that it is the same form of microbe that he states is the cause of cholera.

DR. SALMON stated that the organism Klein described in his last paper, from its form, appeared to be very similar, if not identical with, the one he is working with, and he was struck by the fact that Klein stated that the germ with which he experimented had no effect on pigeons. Dr. Salmon had inoculated two pigeons with the virus in question. One of these died and the

Digitized by Google

other is very sick. The germ he is experimenting with appears to be identical with the one which Pasteur describes in France, and it may be identical with the one Klein has described, and he may possibly be mistaken as to its effect on pigeons. As far as the form goes, it may well pass for the germ he is now working with.

DR. REED said that this paper is an argument in favor of more definite practical action in every State of the United States, for the protection of the people against this disease. There should be inspectors appointed to visit the slaughter houses and inspect the swine or other animals liable to this disease, and see that infected animals are not killed and placed in the market. He thought it highly necessary that our State boards of health should take such action as is essential to prevent the killing of these animals, and the spread or possible spread of these diseases among the people.

DR. SALMON said there was one point of which he would like to speak again, that is, the relation of swine plague to human life. He did not think that swine plague can be transmitted to human beings. It has been investigated by a great number of people who have been exposed to the virus in all kinds of ways, and he had made many post-mortem examinations himself when he had wounds on his hands, and when if there was such a thing as being infected he would have been infected, but he had never felt any dangerous results whatever, and that has been the experience of all others who have investigated the disease. The danger, it seems to him, arising from it is rather from complications. We know that in typhoid fever of all kinds there are formed chemical substances the exact nature of which has not yet been determined, and they seem to vary a great deal among themselves. Now we have never been able to find out up to this time whether or not in the cooking of the meat the injurious matter is destroyed, or whether it still remains in the flesh, but it seemed to him that perhaps some of the obscure diseases met with in daily practice, and to which it is almost impossible to assign any cause, may be produced by eating flesh of this kind. He thought the experience of almost all health boards would bear him out in saying that the flesh of feverish animals is likely to produce disorders of the digestive tract which are very difficult to treat, and which cause great mortality at certain seasons of the year. It is rather to this class of diseases that he desired to call the attention of the Association, and it seemed to him that the best way of combating this danger is for local boards of health to call attention to the matter, and to do all they can to prevent the killing and packing of hogs which are in any stage of disease.

He hoped this winter to get additional power for the Bureau of Animal Industry which will enable him to do something toward checking this disease and limiting the amount of it in the country. He will do all he can in this direction, and must rely on the local boards of health to protect the people.

He thinks a swine plague is a contagious disease which arises only from contagion from infected animals, just as smallpox arises from contagion with the person infected with it.

DR. BRYCE said that this matter interested him very much, especially the suggestion that legislation on the subject be urged by this Association, in order that hogs may be inspected, and that whenever an epidemic breaks out some more stringent measures be adopted than exist at present. He spoke feelingly on the subject, he said, from the fact that while it is true that Canada is at present under the accusation of having brought smallpox into certain parts of the Union, the United States lies under the accusation of having transmitted to the Province of Ontario an epidemic of hog cholera during the past season. The history of it apparently is that hogs sick with the disease were carried down the St. Clair River and washed up on the shores of one of our counties, and in the county of Essex the disease spread some five months ago so widely that the Provincial Government, and along with it the Dominion Government, took extended precautions, under their epidemic act regarding animal diseases, to limit the disease. If his recollection served him right, 150,000 hogs have either died from the disease or been slaughtered in consequence of its existence. It seemed to him a peculiarly appropriate subject for this Association to discuss. Dr. Salmon has discussed it. Dr. Bryce thought that some method for both isolation and prevention should be urged upon the legislatures of this country, and the same legislation, he was sure, would be carried out as far as possible in Canada.

DR. REED offered a resolution urging national, State, and municipal legislation for the protection of citizens from the sale of diseased meats by proper legalized authority.

DR. RAYMOND hoped we will not overlook other diseases of animals. While hog cholera is undoubtedly injurious to animals, as Dr. Salmon has said, it has never been proved that it can be propagated to human beings or contracted by them. We have, on the other hand, a number of diseases which are contracted by human beings from animals. He trusted we would not forget that most important of all diseases, tuberculosis of cattle, and this Association can do no better work than make a recommendation on the subject in this connection to boards of health or inspectors —recommending not that they simply inspect in a superficial manner, visiting slaughter-houses for inspection not after the carcasses are prepared for inspection, but inspect them before such preparation is made. Thousands of carcasses are put on the market in this way when they would have been rejected had they been inspected beforehand by the officer. No man can judge intelligently of a carcass simply from its appearance, except in rare cases. Thousands of carcasses of animals which have died from pleuro-pneumonia and other diseases, have been passed by inspectors who gave their attention only to the carcass itself. He thought the medical profession has been largely benefited by the work done by veterinary surgeons, and in his judgment no board of health is established on a proper basis unless it has upon its staff a competent, educated veterinary, whose duty it shall be to inspect animals in the process of being slaughtered when the viscera can be examined and any disease thus be detected,

DR. JAMES desired to bring out one point. In certain localities and at certain times, with hog cholera prevailing, it is also known that the chicken cholera seems to rush along in a close circuit with it. He would like to know to what extent; and when chickens feed upon the remains from the poisoned animals, how far the

Digitized by Google

disease is carried to these chickens. Has that point been brought out by the investigation?

DR. SALMON said that he had made a number of experiments from which he hoped to determine that point. So far, it has not been worked up with any satisfactory results.

MR. BROOKS said that this is a commercial question as well as a question of health. What Dr. Raymond has said in regard to cattle is essentially important, quite as important as what has been said in regard to cholera of hogs. Only those who take an interest in public affairs abroad as well as affairs at home, realize how much this country has suffered within the few years past from a resistance on the part of the German Government, and especially on the part of the German Prime Minister, who is practically more the government than the Emperor himself, to the sending of cattle and hogs to Europe from our own country. This opposition is defended upon the ground of the effect on the health of the people, both of France and of Germany, and concerns the export of cattle in an improper condition, either in regard to the animals themselves before they are killed, or in regard to the manner of packing them. This resistance has attracted the attention of our government and become a subject of great commercial importance to farmers, to producers, and to the country at large.

It, therefore, seems an eminently proper thing for the American Public Health Association, interested as it is in everything which pertains to health, to take some practical notice as is proposed in regard to the results before it. He, therefore, would most heartily second any motion made to investigate further and report on this subject.

THE PRESIDENT called attention to the fact that there are many diseases in this country which are called hog cholera, but which are as unlike as smallpox and measles. If Klein is as honest as he is capable, we must conclude that the hog cholera which we know in this country, the specific contagion of which Lehman claims to be a micrococcus, and the disease produced by a specific germ cultivated and known as Klein's bacillus, are two different things, and both cannot be right. There must, therefore, be some doubt as to the two diseases. Dr. Reeves is inclined to think that the two diseases are different; that the hog cholera known in this country is not the hog cholera cultivated by Klein.

EVENING SESSION.

DR. J. M. TONER, of Washington, delivered an

ADDRESS OF WELCOME.

He prefaced his remarks by saying that it had been hoped to have the presence of the President, but that he had received the following autograph letter from him:

EXECUTIVE MANSION,
WASHINGTON, Dec. 7, 1885.

DR. J. M. TONER:

MY DEAR SIR: I am sorry that the condition of the public business is such that I cannot accept the invitation which you kindly tendered me on behalf of the American Public Health Association, to attend its annual meeting to-morrow evening.

I beg to assure you that my expression of regret is not merely formal, but actually indicates a sense of deprivation which attends an inability to give by my presence, as requested, the fullest endorsement of the objects and purposes as well as the work of the Association.

Surely the advancement of sanitary science and its practical application to the public health, are of immense importance to the people of our land. Of course, the value of efforts in the direction of a better understanding of the causes of disease, and protection against the same, is too palpable for suggestion or argument. But I do not think the advantages of an improvement in the condition and sanitary surroundings of the homes of our workingmen, and of the poor among us, are sufficiently appreciated. Healthful and comfortable habitations indicate the best features of a country's prosperity and advancement, and men with good health and wholesome surroundings are apt to be contented and useful citizens.

The difference in the death-rate of cities and localities, unexplained by natural and inherent causes, is of itself enough to give great prominence to the work of the Association, and if this beneficent organization shall succeed, as it ought, in impressing upon municipalities the duty of sensible and thorough sewerage, a plentiful and pure supply of water, and general cleanliness, together with a proper construction of school-buildings for the children of their citizens, it may well point with pride to its achievements.

With the hope that the Association may be the means of constantly increasing benefit to the country, and with expressions of heartiest sympathy with its work.

I am, yours sincerely,

GROVER CLEVELAND.

President Cleveland was then unanimously elected an honorary member of the Association. He is the first citizen upon whom this honor has been conferred.

COMMISSIONER EDWARDS, of the District of Columbia, followed with a few well-chosen words, and bid the Association welcome to the city in the name of the citizens of the District and of its government. He took occasion to say that it was not necessary to tender them the freedom of the city; for in this, the capital of a great nation, it was the birthright of every American citizen.

THE PRESIDENT then delivered his

ANNUAL ADDRESS.

He paid a high compliment to the local Committee of Reception for their excellent programme of arrangements. He said that every assembly, such as the one he addressed, moves forward another day's journey the ark of the sanitary covenant. Humanity is bettered and made happier thereby. In these days of political struggles and diverse interests, we hear much of the various means for the advancement and protection of the manufacturing, mercantile, agricultural interests, and many others of less extended importance. But what question of mere business interest can compare, either in importance or extent, with the general and individual interest which every man has in life and health. The national legislation is liberal in many matters, and ought to be equally liberal in providing for the public health. We are to-day at the very threshold of great possibilities in preventive medicine, and the central government should foster every effort for the success of the work in

Digitized by Google

which sanitarians are so heartily engaged. He urged that a national biological laboratory should be established at the national capital to aid in the study of contagious and infectious diseases, and hoped the present Congress would be influenced to establish a health bureau which would be a blessing to the whole country.

(To be continued.)

NEW YORK NEUROLOGICAL SOCIETY.

Stated Meeting, December 1, 1885.

THE PRESIDENT, W. R. BIRDSALL, M.D., IN THE CHAIR.

DR. WM. A. HAMMOND read a paper on

UNILATERAL HALLUCINATIONS.

The fact that hallucinations of sight and of hearing may be unilateral—that is, discerned by one visual or auditory centre only—has long been known, though it has not, even at this day, attracted the degree of attention which Dr. Hammond believes that it deserves. Several authors have considered the matter from a more or less philosophical standpoint, and have brought forward interesting cases in support of their views. The first reference to the fact that hallucinations may be one-sided, which had come under his notice, was made by Calmet, it being a case of hallucination coming from the left ear. Baillarger cited two cases of hallucinations of hearing occurring in but one ear. Other writers who had contributed to the subject, and cited by Dr. Hammond, were Michea, Schroeder von der Kolk, Alexander Robertson, E. Regis, and Dumontpallier. Erroneous impressions, of different character, occurring on either side, had received attention at the Medical Congress at Rouen in 1883.

Dr. Hammond then gave the histories of several cases of unilateral hallucinations which had come under his own observation. The first was that of a gentleman in good general health, who contracted the illusion that the ticking of a clock on the mantlepiece consisted of articulate words; after a time it sounded like human speech, and appeared to give commands, such as not to eat of soup, not to drink wine, etc. It was learned that these illusions came only through the left ear, and never through the right; but hearing in other respects was not the least impaired in either ear. The patient did not allow himself to be deceived into the idea of accepting these commands as realities; yet he was influenced by them in his actions. This case, and the one next mentioned, are referred to in Dr. Hammond's work on insanity.

Case II.—A young lady, of good mental development, but of delicate physical organization, was for several months almost constantly troubled with apparitions of various kinds of faces. A few weeks before they first appeared she had looked at engravings of Greek and Roman masks, which had made a strong impression upon her. If she closed either eye, about half of the faces would disappear; and if she closed both eyes, all would disappear, but would return again in a little while, although less distinctly. By imitating the experiment of Sir David Brewster—pressing on the outside of the globe of either eye so as to produce temporary strabismus—the patient could make any face appear double which had been visible for several minutes. There was no impairment of vision of any other kind, and no abnormal ophthalmoscopical appearances. The peculiar features of this case were, that the images in question were divided between the two eyes, part being seen in the one and part in the other, showing, therefore, the distinctness and divisibility of the action of the two visual centres, and the fact that the stimulus of a strong light was necessary in order that they should be developed.

Case III.—A young man received a blow just above the left ear. A few weeks subsequently, while engaged as a salesman, he saw a large black cat sitting on the floor immediately before him. He had no doubt of the reality of the occurrence, until he walked toward the animal, when it receded as far as it was when he first saw it. After this the cat seemed to follow him wherever he went, but his sense of touch was never deceived. The image was largest and most distinct in the evening, and during the paroxysms of pain at the seat of the injury on the head, which returned several times a day. He discovered, on shutting the eyes alternately, that the vision occurred only on the side corresponding to the injury. There were no abnormal ophthalmoscopical appearances nor disturbances of vision in other respects than that mentioned. That there was serious brain lesion, involving probably the left optic thalamus, Dr. Hammond said he had no doubt. He had also been of opinion that there was fracture of the inner table of the skull at the point at which the blow had been received, and he proposed trephining, which was not consented to.

Case IV.—A lady, about 50 years of age, became the subject of most malignant persecution through anonymous letters, the sender of which she did not know. While thinking of who the person could be that sent the anonymous letters, she happened to look out on the bay window and saw a man and woman standing in the opening. For a moment she did not doubt the reality of the appearance; but, when she arose, they gradually faded from view. Afterward they reappeared several times in the month, and finally ceased to appear altogether. The interesting feature of the case was that the man was always seen with the right eye, and the woman with the left. If she closed the right eye, she saw only the woman; but, if she closed the left eye, she would see only the man. The vision could be brought on by lying down, with the head low. Dr. Hammond thought that nothing could be more confirmatory of the idea of the independent action of the two visual centres than such hallucinations; indeed, he thought they are strong evidence of the duality of the brain. None of the cases which Dr. Hammond had cited went to support the view that unilateral hallucinations are due to disease or derangement of the brain of special sense involved. Indeed, it is difficult to conceive what connection can exist between disease of the eyes or ears and a hallucination existing in the corresponding side; for, if such disease causes a unilateral hallucination, we should expect bilateral hallucinations to be the result of disease of both eyes or ears. Dr. Hammond thought hallucinations are produced by disease or disorder of the central organ of perception, probably of the optic thalamus, and that such erroneous sensorial impressions, when limited to one side, are evidence that the visual,

Digitized by Google

auditory, or other sensorial centre of the corresponding side, is the starting-point.

DR. LEONARD WEBER related a case which he thought would interest Dr. Hammond as going to support the view which he seemed to entertain, that unilateral hallucinations are not associated with disease of the special sense concerned, but with an affection of central origin. The man came under his observation in 1879, at which time he was thirty-seven years of age, strong, healthy, very active in business, but in consequence of domestic trouble and mental strain he began to lose sleep, was sensitive to strong light, loud noises, etc., and from 1879 to 1881 was subject to hallucinations connected with the left ear. On going to bed he would be unable to sleep for two or three hours because of whispering noises, growing louder and louder, heard in the left ear, and of two kinds, one soothing and another demandatory. A careful examination by himself and by a specialist in diseases of the ear, failed to reveal anything wrong connected with the auditory apparatus. When the patient's circumstances changed, and he was enabled to lead a peaceful life, the hallucinations disappeared, and had not returned.

DR. E. C. SPITZKA had not heard the entire paper, but being familiar with the author's views regarding the function of the optic thalamus, he was somewhat surprised that he had not tried to harmonize his observed facts with the anatomical and physiological facts which had been incontestably established during the past decade. Lewes, upon whom Dr. Hammond probably relied chiefly for support of his views, expressed his ideas regarding the functions of the optic thalamus as many as twenty-five years ago, and what he wrote was mere guesswork. If he is supported in part by recent accurate methods of research, such as the study of atrophies and other methods, it is a mere coincidence. Dr. Spitzka said his own views regarding hallucinations are directly opposed to those of Dr. Hammond. He believed that hallucinations have their seat in the cortex, and not in the optic thalamus or any of the lower ganglia. The optic tract and thalamus may have undergone secondary atrophy, following enucleation of both eyeballs, yet the person will be capable of having hallucinations, showing that hallucinations do not have their seat in the optic thalamus. The case cited by Dr. Hammond, in which, during her hallucinations, the patient saw the figure of a man and woman, showed the exercise of mental qualities which could have their seat nowhere else than in the cerebral cortex. Dr. Hammond had asked, whether he did not believe a hallucination to be something which had been previously registered in the memory and which was projected outward. He would reply that, without quibbling with terms, that was precisely what he meant by a hallucination.

DR. M. A. STARR related the facts in a case reported by Vetter, in which a patient having right hemianopsia, imagined that she saw people sitting at her right side, which was the blind field of vision. By a process of exclusion it was shown that the lesion could not have existed in the optic thalamus, but must have existed in the occipital lobe. Dr. Starr thought that in all probability the source of hallucination in this case was cortical irritation. Certainly in a great many cases cortical irritation would produce hallucinations; this is observable in meningitis in which the optic thalamus is not implicated.

DR. W. M. LESZYNSKY recalled the case of a woman fifty years of age, in an insane asylum, suffering from mania, who was in the habit of sitting hours at a time with the left ear inclined toward a table, sending and receiving telegraphic communications she said. She did not receive the telegraphic communications with the right ear, which she said was only for general use. Hearing seemed to be normal, perhaps that in the left ear was a little more acute than that in the left ear.

DR. SACHS referred to a case of hemiplegia with tumors in the optic thalamus, reported by Minot, and asked Dr. Spitzka whether he could imagine an excitation of the cerebral cortex giving rise to an image or hallucination, the revival of such image not being due to an antecedent peripheral irritation.

DR. L. J. CORNING asked why hallucinations which might be produced by impressions coming from the peripheral nerves, might not also be produced by an irritation at any point in that peripheral tract, as in the thalamus. We all admit that the higher forms of conception take place in the cerebral cortex.

DR. C. L. DANA said he would like to hear the subject discussed which Dr. Hammond probably wished to bring before the Society, namely, the duality of the brain. So far as the mechanism of hallucinations is concerned, he thought all would agree with Dr. Spitzka that it is essentially in the cerebral cortex. But the exciting cause may be a peripheral irritation acting upon the psychopathic centres.

As to the duality of the brain, he thought there are many more arguments against the proposition than for it; but the subject is one of great extent, and could hardly be discussed at this hour. The cases of hallucinations did not, it seemed to him, prove much, because only a small part of the psychical mechanism was involved. On the other hand, the experiments of Dumontpallier proved little, because hypnotized subjects can be led to do almost anything by slight suggestion. But pathological observations, the results of hemiatrophies, of tumor on one side of the brain, studies regarding language, etc., all go to show that the two cerebral hemispheres have certain distinct functions, and that there are not two halves of the brain, each possessing about the same function.

DR. CHARLES HEITZMANN said that, although he is not a specialist in this department, he had given considerable study to it, and he had received the impression that neurologists are not entirely clear in their ideas concerning the seat of irritation which causes hallucinations. Let the physiological fact be remembered that an impression upon our senses can be brought forward at any time in the shape of a protracted sensation or hallucination. Thus a peculiar sound may be heard which is merely the image of a real sound, and constitutes a hallucination. Everything which we have learned is deposited in the brain, especially in the gray substance. In the case of the black cat, could the man have had a hallucination of a black cat, if he had never seen a black cat? I doubt it. Wherever the centre for the image of the black cat may be, if any portion of the nerve tract leading from the retina to that centre be disturbed, it will be likely

Digitized by Google

to excite that centre, and the image of the black cat will be revived. The special point of interest connected with the cases related was that they were unilateral. He asked if that might not be explained on the supposition that the irritation being upon the one side led to the centre for the given image upon that side only.

DR. SPITZKA said, with regard to the duality of mind, that there can be little difference of opinion regarding the following facts: First, that the two cerebral hemispheres are alike in structure, the variations being no greater than in other symmetrical organs, if allowance be made for a higher type of development; the hemispheres are united by a symmetrical commissure; they have corresponding peripheral tracts; they have about the same distribution of retinal fields; post-mortem examinations of the brains of the insane go to prove that the hemispheres are symmetrical; one hemisphere may be practically destroyed, and the individual still retain power to exercise the several faculties of the mind, as reasoning, memory, judgment, etc., yet, however, that there would be paralysis or other symptoms. But it is a different matter entirely when it is suggested that unilateral hallucinations can exist when the corresponding hemisphere is perfectly healthy.

DR. HAMMOND, in closing the discussion, said it was not his object in reading the paper to discuss specially the function of the optic thalamus. He might say, however, that he believed a person could have hallucinations without an optic thalamus at all, provided he had a cortex; but he believed also that he could have hallucinations without any cortex, provided he had an optic thalamus. In the former case the hallucinations would be due to revival of past impressions; in the latter case they would be original, having nothing to do with former associations. A man without an optic thalamus could have an idea of a cat in the abstract, but he could not have a hallucination of a particular cat, unless he had an optic thalamus. He believed that ideation resides in the cortex. With regard to the duality of the mind, many arguments might be brought forward, but the time would not permit.

BALTIMORE ACADEMY OF MEDICINE.

Stated Meeting, December 1, 1885.

THE PRESIDENT, J. J. CHISOLM, M.D., IN THE CHAIR.

EVISCERATION OF EYEBALL BY THE NEW METHOD.

DR. J. J. CHISOLM related a case of evisceration of the eyeball after the plan recently recommended. The operation consists in completely excising the cornea by means of a circular incision around its margin. The contents of the ball are then to be entirely removed, leaving the sclerotic intact. The advantage claimed for the operation, is that the socket tissues are not disturbed, neither is the muscular apparatus of the eye interfered with; besides, the stump left after cicatrization leaves an admirable seat upon which to locate the artificial eye. The operation itself is a very simple one, and can be performed much more expeditiously than can complete enucleation, but convalescence is so very tedious, and at times gives rise to such painful and alarming symptoms, as occurred in his case, that in future he will confine himself to the old plan of complete enucleation.

Dr. Chisolm said that it is his usual custom to allow a patient to go about his affairs very soon after the operation—at the outside, twenty-four hours; but in the evisceration operation, even up to the fourth day and later, there were such œdema and pain that he could not think of allowing the patient to be from under his observation. He had never had such an experience with the old method.

DR. S. C. CHEW wished to know if sufficient anæsthesia could be produced by the use of cocaine to enable one to perform this operation without painful sensations on the part of the patient.

DR. CHISOLM thought not.

PARALYSIS THE RESULT OF A FALL.

DR. A. B. ARNOLD related a case which occurred at Bay View Asylum a year ago. It occurred in a woman five months pregnant. She fell from the second story window, striking upon the head; when picked up she was senseless, and remained so for three days. As a consequence of the fall, abortion was brought on. At present she has paralysis of both lower extremities, complete anæsthesia on right side, is deaf and also blind on this side. She evidently has some spinal trouble, as she complains of that sensation so common to these troubles, "as if a belt were being drawn about her waist;" also has some enfeeblement of the sphincters of bladder and rectum. In addition, there is a peculiar nervous jerking about the head, which has continued for one year. He thinks the lesion is located about the inferior third of the internal capsule, extending up and involving the optic and auditory nerves at their point of crossing, and also that the nerves of sensation which come off at this point are also affected. The pupils responded normally to light. She had never had any trouble previous to the fall.

DR. CHISOLM asked if any ophthalmoscopic examination had been made. He said he was prompted to ask this question by a case which recently came under his observation. It occurred in a man who had received a severe beating, and among the results, loss of vision began after about six weeks. He examined him, and found anæsthesia of the fifth nerve, the hearing involved, and several small retinal hemorrhages around the point of entrance of the optic nerve.

DR. S. C. CHEW related an interesting

CASE OF EMPYEMA.

He had been called in consultation to see a case which occurred in a patient who for several days had suffered from severe dyspnœa. The night before he saw the patient he had had copious expectoration of matter, the nature of which he could not describe, as it was not saved. This was followed by immediate relief from the difficulty of respiration. Upon physical examination of the chest the left pleura was found to be about two-thirds filled with fluid. Shortly after his visit, the patient suddenly died with profuse vomiting of purulent matter, as well as the passage of quantities of it from the bowels. From such symptoms he thinks it highly probable that perforation took place through the diaphragm into the stomach, and that the fluid was dis-

Digitized by Google

charged in both directions, through the œsophagus and through the intestines. He had searched the literature on the subject, but had found no case terminating in this manner recorded. Physical examination of the chest, made before the first expectoration of matter, showed the pleural cavity to be entirely filled with fluid. More recently he had seen a patient at the Baltimore Infirmary whose physiognomy was indicative of pulmonary trouble. Percussion over right side of chest gave decided resonance both anteriorly and posteriorly. On auscultation on same side there was pronounced Hippocratic succussion. Shaking the patient while one ear was still on the chest gave a sound very similar to that heard when one shakes a jug partly filled with water. No discomfort at all was noticed, neither pain nor dyspnœa. He thought the absence of dyspnœa could be explained on the ground that the air probably distended the pleura (and this compressed the lung) so gradually that this lung, as well as the healthy one, had sufficient time to accustom itself to its abnormal relations. Whether perforation was due to ulceration outward through the pleura, from the wall of a cavity in the lung, or whether it was due to a loss of substance occasioned by a point of inflammation upon the visceral pleura, and thus perforation taking place in the reverse direction, he could not say, although symptoms sufficiently marked were present to point to either mode. In his opinion surgical interference should be resorted to as soon as the condition of empyema is made out.

DR. ARNOLD had seen a case of empyema in a child. It occurred on the right side, ulcerated through the diaphragm, and discharged its contents into the abdominal cavity. The child died from shock. He considered it somewhat remarkable how rarely phthisical patients show any signs of discomfort from interference with respiration, even though their lungs may be riddled with cavities.

DR. CHEW looked upon this as due to the slowness of the pathological process, this enabling that portion of the lung which is healthy to increase its physiological activity. He also thought, in view of the fact that cavities so frequently form near the pleura, that it is singular perforations from them are so rarely found.

DR. CHISOLM said serous sacs resist perforation.

THE COCAINE HABIT.

DR. J. C. THOMAS said, since he had been told that in some of our principal cities the cocaine habit was being acquired largely, he would like to ask if any member had ever seen a case of it; and if the report is true, did not the gentlemen think that the medical profession should take some steps to prevent the reckless prescribing of this seductive drug.

DR. CHISOLM related two cases in which decided loquacity was produced by the introduction of cocaine into the cavity of a decayed tooth. In speaking of cocaine tablets, he referred to a condition amounting almost to a slough, that was produced on the buccal surface of his own cheek from the application of one of these tablets to the gum and allowing it to remain until dissolved. From this, he hardly considered their use advisable in nasal catarrh.

CINCINNATI ACADEMY OF MEDICINE.

Stated Meeting, November 30, 1885.

THE PRESIDENT, SAMUEL NICKLES, M.D., IN THE CHAIR.

SUPERFŒTATION.

THE discussion of this subject was postponed from the meeting of November 2d, when DR. J. H. TATE presented a specimen which he had removed from a woman who had been confined on the 15th of October preceding. The history of the case he gave as follows:

The patient menstruated last on the 21st of November, 1884. Within a few days after this she complained of nausea similar to that which she had before suffered when pregnant, and inferred that she was again in this condition. The nausea persisted for some time, and no menstrual flow appeared up to the time the labor occurred, constituting a period of 328 days. Was this, the speaker asked, a case of protracted gestation, or what was it? The woman believed herself pregnant, and all the symptoms indicated the correctness of her belief. In the latter part of August she began to experience what she supposed were the premonitory symptoms of labor, symptoms that persisted until labor occurred. The labor progressed with nothing of an unusual character until the child had been delivered; this occurred about 9 P. M. The placenta came away without difficulty, and was remarkable only for its small size compared with the healthy, well-developed child that preceded it. Examination showed it intact, and possessed of no peculiarities. The uterus contracted firmly; the bandage was applied, and the speaker departed, leaving his patient in a good condition, as he supposed.

The next morning the nurse reported that shreds of tissue resembling the membranes had passed during the night. Upon examination, he found some pieces of the membranes and portions of what resembled placental tissue. A mass of considerable size was found in the lower portion of the uterus. Gradual traction upon this brought away an entire placenta projecting from which could be seen the remains of a cord. This specimen was presented for examination. The first placenta was, unfortunately, lost. No second fœtus was discovered; but the speaker considered the case reported one of superfœtation. The fact that there were two placentæ of different sizes in the womb would argue that a second conception had occurred about three or four months after the woman first became pregnant. From the fact that but one child was delivered and from the appearance of the cord it would appear that one child died, but that the placenta belonging to it continued to develop, owing in all probability to the stimulus to the uterine circulation caused by the presence of the other placenta.

Some authors deny, the speaker continued, that superfecundation can occur, but the arguments supporting their opinions are not convincing. The old idea that the ovule and seminal fluid cannot meet and cause a second conception is false. The old Hunterian idea that the decidua is a closed sac has been abandoned. There is no barrier to the entrance of the ovule into the impregnated uterus; neither will the mucous plug in the cervix prevent the entrance of the seminal fluid. It has been

Digitized by Google

asserted that the only proof of such an occurrence is to be found in the discovery of fresh corpora lutea of ages to correspond with the pregnancy.

Tyler Smith reports the case of a woman who was delivered of two children five months apart; and Stern, a case in which a woman was delivered of a child at four months and another at eight.

Our knowledge of what is really going on during menstruation is very limited. One gynecologist tells us that he has seen, in more than one living subject, the ovule discharged at a time midway between the menstrual periods. Among other instances, the speaker referred to a case that occurred in Strassburg, in which a woman gave birth to two fully developed children, the second 140 days after the first.

This phenomenon and others like it, many attempt to explain by the assertion that the two children bear the relation of twins, one of which fails to develop to as full an extent as the other, owing probably to the supposed fact that it does not receive an equal share of nourishment, and must therefore remain a longer time in the uterus. This does not seem rational; and the only case in which such an explanation could be given would be in those rare cases of a double uterus. In the case which occurred in Strassburg, Professor Esselmann kept the woman under observation until her death, after which a single uterus was revealed.

DR. JAMES T. WHITTAKER remarked that we should first have a definite understanding of the meaning of terms. Superfecundation and superfœtation, which are often used indiscriminately, do not mean the same thing. Superfecundation signifies the impregnation of multiple ova after different acts of sexual congress whether from the same or different males, but always, and this is a *sine qua non*, of ova furnished at the same period of ovulation. The question whether superfecundation is possible has been raised. If we reason by analogy from the lower animals, as has been done by the reporter of the case this evening, we should have to accept the possibility of superfecundation in man. A mare crossed by a horse and a jack, may produce both a horse and a mule, and dogs, cats, and other animals beget offspring the product of the various animals with which they have come in contact. But reasoning by analogy is not always safe. The clearest proof of the possibility of superfecundation in man would seem to be the simultaneous birth from a white woman of black and white children. Such cases are upon authentic record. But the intercourse with the males of the different races occurred of necessity within the same period of ovulation. Yet this evidence which seems so clear, is not so in reality. For it is well known that children the offspring of crossed races resemble more distinctly one or other parent, so that a white woman may beget white children from a negro, or a black woman may beget black children from a white man. The birth of twins, one white, the other black, would not therefore be proof positive of superfecundation. It would simply prove that the female of one race had been impregnated by the male of the other race. There is no positive proof of the possibility of superfecundation, though reasoning by analogy from the lower animals it may be said not to be impossible.

On the other hand, superfœtation—that is, the impregnation of ova from different periods of ovulation—is a physiological impossibility; for, when an ovum has been impregnated, further ovulation ceases at once. This is not a rule to which there are exceptions. It is a law, and, as a law of nature, it is immutable and without exception. There is a simple proof of this; so simple as to be patent to every observer. I shall allude to it again, but not to withdraw all interest from the discussion at the start by the exhibition of proof which is universally demonstrable. Let us look at the evidence which has been so plausibly presented in favor of superfœtation. This evidence, so far as the specimen is concerned, is valueless; for there is here nothing but a placenta delivered one day—one day only—after the delivery of a birth at term with all the adnexa. Such a case would not fall by any possibility under the domain of either superfœtation or superfecundation. There is no fœtus; there is only the suspicion of a cord to the second placenta, and the case could at most be only the placenta of a twin which had been blighted early and which had been absorbed.

But the case, such as it is, has been used as the text of a discourse in favor of superfœtation, and we may regard the arguments, if not the specimen. The evidence presented by the reporter of this case is based upon the occurrence of menstruation during pregnancy, upon the birth of children on widely distant times, upon the occurrence of conception during lactation, which is considered analogous to gestation, and upon analogy from lower animal life.

As regards menstruation during pregnancy, it is answered that not every hemorrhage is a menstruation. In the few exceptional cases of persistent menstruation, it is noticed that the periodicity of the occurrence disappears. These patients often remark upon the fact that they have been unwell twice in a month, instead of once. True menstruation does not occur in pregnancy. True menstruation is physiological; metrorrhagias are pathological. True menstruation is a companion of ovulation, and, like it, is distinct in time. Any hemorrhage during pregnancy is not a menstruation. It is a metrorrhagia, and is no more entitled to be called a menstruation than is the show of blood which immediately precedes a labor.

The evidence adduced to support the statement that children have been born of widely different ages is based solely upon differences in length and weight, or differences in the degree of development. No evidence could be more fallacious. Think for a moment what differences are observed in normal single labors. One child weighs five pounds, another ten, and equal disparity is observed in length. Shall these children be said to be of different age? So it is with twins. One of twins is often smaller than the other, and this difference has been observed in twins enveloped in the same membranes, the product, hence, of the same egg. In Martin's case one of the twins was 3⅛ inches shorter and 18 ounces lighter than the other, and if such difference has been seen in twins from the same ovum, what greater differences do we not encounter in twins from different ova. I am speaking now of conceptions from the same coition. Do we not frequently see evidences of arrest of nutrition and development in one member or organ of a child, whether of single or multiple birth, and is it not universally admitted that the gross differences we see in the whole body are easily explicable by arrest of development of one child? Why

Digitized by Google

should we appeal to something mysterious and physiologically impossible to explain, phenomena which admit of explanation in a simple, obvious way. Is it at all surprising that twins in a bilobed uterus should experience a different degree of development, and one should be born further advanced than the other, or is it at all surprising that twins, one in the uterus and the other extrauterine, should show differences of development. Would it not be more surprising if they were developed to the same degree under these widely different conditions? So differences in weight or length or stage of life are readily understood without appealing to the possibility of superfœtation, a most superannuated doctrine. I take it that these cases are twins from the same period of ovulation, and one has been stunted while the other has grown. This accident happens very frequently in the case of twins. In the lower animals differences of this kind are observed as a rule.

The reporter this evening seems to put particular stress upon the occurrence of births at different times as evidence of superfœtation. He has cited cases in proof with differences amounting at times to 120 days. It must have struck the members who have listened attentively to these reports how many of the cases date from ancient literature. Ancient literature abounds in marvels. Cases of this kind grow fewer and further apart as we approach the period of the study of pathology or morbid anatomy, and they almost cease entirely within the last quarter of a century. Kussmaul and Schultze examined with patient detail all the cases they could collect, and what did they find? Why, that not a single case bore the test of criticism. The only authentic cases where any real wide disparity of time occurred admitted of easy explanation by the premature birth of one of twins conceived at the same time. Such cases are not so very rare in the literature of medicine. One child is born while the other is carried longer, even to full term.

It is quite useless to consume time with the possibility of conception during lactation. That fact is universally conceded. True menstruation sometimes establishes itself during lactation, true menstruation preceded or attended by ovulation with possible pregnancy as a matter of course. But lactation is not gestation. Gestation absolutely precludes ovulation as a law, while lactation excludes it only as a rule. Moreover, it is useless to reason by analogy from lower animal life. In the cases in which superfœtation is said to occur, the conditions are very different from those of man. In the deer, for instance, according to the observations of Ziegler and Bischoff, after impregnation and the process of segmentation is complete, the fecundated egg lies quiescent in the uterus, undergoing no development whatever for a period of four and a half months. It is not impossible that ovulation may reëstablish itself during this period of quiescence.

I have said at the start that there is a proof that puts this whole question beyond a doubt. It is so simple and easy that any one may see it for himself. It is a proof demonstrable to the senses, physical, precise, or, as we say, scientific. I will cite it now. Whatever doubt regarding menstruation, there is no doubt, it will be conceded by everyone here or elsewhere, that conception requires an egg. An egg comes from an ovary, and an ovary in furnishing an egg suffers rupture of the capsule, or follicle, the Graafian follicle containing the egg. If anyone here was asked for the proof positive of the pregnancy in the body of a woman, he would turn at once to the ovary and look for a Graafian follicle. All changes in the uterus might have disappeared, but the Graafian follicle would show its wound as long as nine months after conception. In a recent case the follicle would be filled with fresh blood, black, the so-called *corpus nigrum*. In an old case the blood would show retrograde changes, would become yellow, to constitute the so-called *corpus luteum*. I repeat, conception demands a previous ovulation. There may be a false menstruation, so called, without ovulation, but surely no conception without ovulation, and no conception without a *corpus nigrum* and, subsequently, a *corpus luteum*. Well, what has all this long since demonstrated and universally accepted fact to do with superfœtation? Simply this. There has never yet been demonstrated a fresh *corpus nigrum* or a *corpus luteum* in addition to that one or those two which furnished the uterus with its contents. They have been looked for often by the advocates of superfœtation, but the search has been abandoned now as fruitless. This fact removes all support for superfœtation. All the speculation, hypothesis, or logic in the world cannot substitute this single anatomical truth, though presented with all the grace of rhetoric we have listened to to-night. Thus, superfœtation ceases to be a fact, to become a myth.

DR. THOMAS A. REAMY said: I shall defer what I have to say regarding the case brought before our notice by the reporter, until the latter part of my remarks, since I desire in the beginning to reply to the sweeping declaration of my distinguished colleague and personal friend who has just preceded me.

He has taken strong ground upon the subject of superfœtation, and when he says that the phenomenon is a physiological impossibility, because ovulation never occurs during gestation, I accept the challenge, and join issue with him, notwithstanding I must meet him in his own realm of physiology, a department in which he is high authority.

Now nothing is better known than the special independence of the functions of ovulation and menstruation, although their general association is admitted. That menstruation, a regular periodical flow of blood from the endometrium, may occur without ovulation, is substantially proven. That gestation, as a rule, suspends menstruation, is also well known; but to this law there are exceptions. I have myself the notes of ten cases in my own practice where periodical menstruation occurred every twenty-six to twenty-eight days until the third month of gestation. In three of these subjects the observation was repeated during two and three pregnancies respectively. The health of the women and the periodicity of the flow negative an ordinary hemorrhage.

The physiological proof of ovulation is either pregnancy, or, in its absence, the corpus luteum. And all physiologists now know that the corpus luteum of pregnancy differs from that of ovulation, not in kind, but in degree only. It is not now as valid proof of pregnancy as formerly.

Dalton, in his celebrated paper before the American Gynecological Society, in 1877, reports a case of careful examination of the ovaries, nine days after a menstrua-

Digitized by Google

tion, which was clinically normal in every respect, and not a trace of a corpus luteum was found. Reeves Jackson, in a paper read before the American Medical Association, in 1884, reports many cases of the same kind.

As for the occurrence of pregnancy without menstruation, it were idle to waste time, for everybody of large experience has seen and reported such cases. I have myself the records of three cases whose confinement I attended, and not one had ever had a single sign of menstruation. Jackson's paper, referred to above, quotes a large number of such cases. Fordyce Barker reports a woman who menstruated regularly up to the time of her first pregnancy, and never menstruated again in her life, although she subsequently bore ten children.

You have all heard of women, for the transactions of obstetrical societies are full of such instances, who have continued to menstruate long after both ovaries have been removed and ovulation was impossible. Enough has here been briefly cited to demonstrate the absolute independence of ovulation and menstruation in special instances.

Again, and this the gentleman has admitted, there is acknowledged to be no mechanical obstruction to the entrance of the spermatozoa through the cervical canal, since the time-honored plug of mucus is not always present, and is no insurmountable barrier when it is, probably indeed favoring the transit of the spermatozoa. Likewise, the Fallopian tube is entirely pervious from end to end on the side opposite to the developing ovum. Again, Coste's investigations have shown that union between the decidua vera and the decidua reflexa does not occur until the third month, or even later, and there is thus a highway permeable both by ova and spermatozoa from the ovary to the vagina.

Now but one link in the chain necessary to the occurrence of superfœtation remains, and this link is the question: Does ovulation ever occur during gestation? My learned colleague says it never does, and with this broad declaration I take issue. When he says that ovulation never occurs during gestation, he includes by the universality of his statement not only the single uterus, but also the bilobed variety; and not only intrauterine, but also extrauterine gestation. However, lest I may seem to take unfair advantage of the breadth of his statement, I will slightly qualify that last proposition in his favor, by limiting the assumed control which extrauterine gestation may have over ovulation to the time which the ovum continues to live.

Now let us examine the evidence on this subject, and first let us take clinical testimony. Dr. Bonnar, of Cupar, reports in the *Edinburgh Journal*, 1865, the following case: A woman was delivered of a living healthy child on the 12th of September, 1849, and on the 24th of January, 1850, of another child also living and healthy, 127 days intervening between the two births. Dr. Bonnar assumes that it is not possible for a woman to conceive under 14 days after delivery, and subtracting this period from 127 days, it would leave but 113 days as the length of time from the conception of the last child until its birth, assuming that conception occurred after birth of the first child. If it be alleged that the first child was premature, then it was delivered four months before full term, which, as it was living and fully developed, nobody would believe. Here, although there was no evidence of its existence, it might be claimed that there was a bilobed uterus, but even if there was, did not that woman ovulate during gestation? If so, then uterine pregnancy does not always suspend ovulation.

In the well-known case reported by Fordyce Barker, "a woman gave birth on July 10, 1855, to a boy at term, and on September 22d, of the same year, 73 days later, to a girl also alive but smaller." Subsequent examination showed this woman to have a bilobed uterus. Who here can deny that she was gestating in one lobe of her uterus while the ovum entered the other? A similar case is reported by Dr. Ross, of Brighton. A woman who had already given birth to six children, miscarried with twins on July 16, 1874, and on the 31st of October, fifteen weeks later, was delivered of a healthy child. Examination here showed a bilobed uterus, each side of which had been impregnated.

I will quote one more case on the clinical side of this question, and for its details I refer you to Tyler Smith's *Manual of Obstetrics*, page 112. A young married woman in her first pregnancy, miscarried at the fifth month, and some hours subsequently she discharged a small clot bearing a healthy ovum of about one month's development. This patient had menstruated regularly during her whole pregnancy. Do you doubt that she ovulated? Can you call in question keen observers like Tyler Smith? Do you suppose that Tyler Smith could not tell a blighted ovum from a healthy one? If you take clinical evidence from anybody, can you desire any higher authority than this great master in obstetrics?

Now such cases in bilobed uteri, whether they be technically cases of superfœtation in the strict limitation of the term or not, are quite germane to the subject under present discussion, in that they offer the strongest clinical proof that ovulation may and does occasionally occur during pregnancy. It is indeed quite fortunate for us in settling this point that a few bilobed uteri have been found, which have carried gestations at widely different stages of development, and thus demonstrated that the ovary may carry on its function while there is a living fœtus *in utero*. Without such cases the opponents of superfœtation have always argued that reported cases are instances of twin fecundation, one of which has been retarded by the growth of the other. In such an abnormal uterus however, retardation of growth is not liable to occur, and the clinical inference beyond question is, that ovulation has occurred while gestation was in progress. Another addition to the clinical aspect of this subject is the occurrence of uterine pregnancy simultaneously with an active extrauterine fœtation. Such cases are not rare, and so many have been reported that it would be a waste of time to cite particular instances.

Now, if my learned disputant admits the evidence of a single one of the cases cited, he must surely modify his inflexible "never." If ovulation, during gestation, be proven in a single case, in others it may be assumed. But, knowing the tendency of my friend to claim all clinical evidence as fallacious, in the absence of physiological or pathological corroboration, let us see if there is any physiological testimony to sustain this position. Scanzoni long ago contended that Graafian follicles enlarge and mature during pregnancy; but he had never seen one that had burst. But Slavjansky saw a fresh corpus luteum in the right ovary of a woman who died

Digitized by Google

in the third month of pregnancy, while the left ovary bore the corpus luteum of the pregnancy which was in progress at the time of her death. This case is from the *Annales de Gynecologie* for 1878. Again, Mayshofer, in the *Wiener medicinische Wochenschrift* for 1876, reports a case of fresh corpus luteum in pregnancy, and at the same time quotes cases of the same character exactly from Kussmaul, Luschka, G. Braun, and Tobege.

After such clinical evidence from such high authority, and physiological facts from investigation of unquestioned ability, how can we resist the inevitable conclusion that ovulation has occurred during pregnancy; and, if ovulation, then from the absence of mechanical obstruction, which absence has been demonstrated beyond doubt, conception may occur, and such conception is superfœtation? The proof is both physiological and clinical.

It is hardly necessary for me to state that while I believe, as I have briefly tried to show, that ovulation may occur during pregnancy, I deem such cases quite rare, and the converse of the proposition to be largely the prevailing rule.

I confess that many of the clinical cases quoted by authors in proof are not in point.

I have just examined the placenta exhibited by the reporter, and am of the opinion that it is a piece of an extraordinarily large placenta, whose major part was delivered shortly after the birth of the child. Consequently I do not esteem this a case of superfœtation, but rather a case of partially retained placenta, which was fortunately delivered spontaneously before organization or sepsis had occurred. I state this opinion with diffidence, for we all know the large experience and great ability of the reporter in such matters.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, November 24, 1885.

THE PRESIDENT, CHARLES MCBURNEY, M.D., IN THE CHAIR.

OSTEOSARCOMA.

DR. MCBURNEY presented a specimen of large osteosarcoma, removed post-mortem from a colored boy, fifteen years of age. Dr. McBurney showed the boy to the Society two years ago. The history of the tumor was that it first appeared as a small swelling on the right side of the lower jaw eleven years ago. Its growth since that time had been uninterrupted. The boy remained in good health up to last July, when the interference with deglutition became so great that it was necessary to feed him per rectum. He died of inanition on August 24.

The microscopical examination was made by Dr. Frank Ferguson, who made the following report:

The tumor is an osteosarcoma with much fibrous tissue and fat. It arises from the right ramus and body of the lower jaw to the right of the median line. Extending from this location is a mass of bone, the antero-posterior measurement of which is seven inches, and transversely it measures eight and one-half inches. Vertically it measures four inches.

This large mass of bone has crowded the left half of the lower jaw and a portion of the right half of the bone much to the left. The inferior maxillary bone is bent at the symphysis, forming an acute angle. One and one-half inches of the body of the bone on the right side, containing two teeth, pass directly backward, from the symphysis, in the median line.

The condyle of the right ramus is found just beneath the right external auditory meatus.

The right half of the superior maxillary bone is much distorted. The last molar in this bone is half an inch below the floor of the right orbit, and three-fourths of an inch from the median line.

The œsophagus and trachea are pushed much to the left, being only one inch from the surface of the neck on that side. The neck extends directly backward, at right angles from the normal line of the vertebral column.

The large mass of bone above described is covered by lobulated soft tissues, composed of fat, fibrous tissue, and numerous medium sized spindle-shaped cells. The bone is simply compact bone-tissue. The tumor is limited by a fibrous capsule. The greatest circumference of the tumor is twenty-nine inches. From the highest level to the most dependent portion it measures eleven inches. It weighs, as presented, seventeen pounds, three and one-half ounces.

MONTREAL MEDICO-CHIRURGICAL SOCIETY.

Stated Meeting, December 4, 1885.

THE PRESIDENT, T. G. RODDICK, M.D., IN THE CHAIR.

CEREBRAL SYPHILIS.

DR. GEO. ROSS now read a paper on some cases of cerebral syphilis which had recently come under his care. He remarked that modern pathologists have confirmed the surmises of the older writers regarding syphilis being responsible for many affections, and have shown that important organs may, and often do, become the seat of syphilitic disorders; they have also shown that symptoms of present disorder may be induced by local inflammation of a specific nature by the invasion of a neoplasm, by softening due to obstruction of diseased vessels, and by the interference of a tertiary swelling of the periosteum, as a result of constitutional disease of the bones themselves. It has been thought, also, that symptoms of cerebral syphilis may be observed whilst the autopsy shows no special changes in the brain.

He regarded the field of brain syphilis as a peculiarly attractive one to the clinician and pathologist, on account of the strikingly different disease-pictures that may be presented, the diagnostic difficulties met with, and the practical importance of the cases. He instanced tabes dorsalis as a disease, in which, in spite of all the attention bestowed on it, it was yet a moot point whether or not it should be looked upon as of syphilitic origin.

Dr. Ross, in this connection, related the case of a patient who had come under his care last winter for exaggerated ataxia. A suspicion of syphilis being entertained, anti-syphilitic treatment was employed and a rapid recovery resulted. He also related the case of a gentleman who had suffered from an eruption on the face for over a year, for which he had obtained no relief by treatment. Suspecting its origin to be syphilitic, although not able to obtain a history, Dr. Ross placed

Digitized by Google

him on a mercurial treatment and his eruption rapidly disappeared; a year or more after he had an occasional epileptic fit and finally he became comatose and his death was hourly expected. Dr. Ross saw him, and from a previous knowledge of his case put down the symptoms as probably due to syphilis; he treated him accordingly with large doses of iodide of potassium and the man rapidly and completely recovered.

The reader of the paper went on to remark how difficult it is to get a history of syphilis in many of these cases, and said that persons who suffer from late developed syphilis of the nervous centres, are extremely likely to give no account of the well-defined secondary symptoms which are so common, and they at times are not even aware that they have ever had any secondary symptoms. The practice of giving potassium iodide as a test in nervous cases was highly recommended, and should be adopted in every case where there is the slightest element of doubt.

Dr. Ross held that there are no pathognomonic signs which point conclusively, without the aid of the history, to the specific nature of the case, and more dependence should be placed on the grouping together of various symptoms than upon any individual symptom. For instance in epilepsy, many cases of general convulsions resemble in almost every respect what is called "essential epilepsy," and yet are due to constitutional taint. They cannot always be diagnosed as such; then the therapeutic test alone will determine the question. According to Dr. Buzzard, in syphilitic cases there is often a history of antecedent pain in the head for months before the first fit. The reader of the paper then related a case of cerebral syphilis, in which there was persistent headache for months, then the patient was seized with violent and frequent epileptic fits, followed by partial loss of power of the right arm and leg. There was in this case a distinct history of syphilis acquired fifteen months before. He was rapidly placed under the influence of mercury by means of inunctions and was quickly relieved of his headache, epileptic fits, and other symptoms. After salivation by mercury he was given large doses of potassium iodide. In this case the lesion was probably situated on the cortex of the left hemisphere.

Two other cases were also related; in one the patient had prolonged pain in the head, followed by sudden left hemiplegia. Under anti-syphilitic treatment, he improved; in the other case there were sensory disturbances, lethargy, mental impairment, and some defect of speech; he had frequent attacks of numbness and spasm of the right side of the body, which left him in a dazed and dull condition. In this case there was no history of syphilis, but, nevertheless, the man was put on anti-syphilitic treatment; he, however, remained only two weeks in the hospital, and was discharged at his own request. Whilst under treatment, no definite attack of numbness or spasm occurred.

DR. HENRY HOWARD, after complimenting the reader of the paper on the excellent manner the cases had been reported, stated that he had seen many obscure affections of the brain due to syphilis, and had seen many apparently hopeless cases recover after anti-syphilitic treatment. In many fatal cases no cause is discovered after death—that is, there is no gross lesion. He believed that, in the future, changes will be discovered by the aid of the microscope, which will fully explain everything. What is necessary is a more exact knowledge of the histological anatomy of the brain, and then the pathological condition will be more readily recognized. Even now, brains formerly considered normal are found, on accurate microscopical examination, to have undergone distinct pathological changes, especially in and about the bloodvessels.

DR. STEWART considered that cerebral syphilitic lesions are much better treated by mercury than by potassium iodide; mercury is an antidote to syphilis, potassium iodide is not. Mercury should first be tried, and inunction is the best method; in this way the remedy is introduced more effectively, even than by hypodermic injection.

DR. A. LAPHAM SMITH related a case of epilepsy where the post-mortem revealed a syphilitic gumma in the brain. There was no history of syphilis.

DR. F. W. CAMPBELL said he had some experience with inunction in the treatment of syphilis, and he had found that at times it is as difficult to get the patient under the influence of mercury by this method, as when mercury is given by the mouth; he had seen some patients salivated by five grains of blue pill.

DR. SHEPHERD, in speaking of the difficulty of getting a history in many cases of suspected syphilis, mentioned several cases in which there were well-marked tertiary symptoms, but no history of primary or secondary manifestations. In one case, that of a medical man, secondary syphilis developed, and absolutely no history of primary sore could be obtained. In tertiary syphilis, he advised first the use of potassium iodide; if that failed, then mercury; and if mercury failed, a combination of the two. He mentioned also that he himself is easily salivated by five grains of blue pill, and he knew of several like cases, and asked whether such a small amount of mercury is efficient to act as an antidote to the syphilitic poison. He thought not.

DR. WILKINS regretted that he had not known that Dr. Ross was going to read a paper on such an interesting subject as cerebral syphilis, as he could have looked up the notes of several most interesting cases. He related the case of a washerwoman who was subject to epileptic fits, followed by great drowsiness, and who, under treatment by potassium iodide, in large doses, rapidly recovered. In this case there had been no pain in the head preceding the fits; and he had seen several similar cases.

Many cases of cerebral syphilis can be recognized only post-mortem, by the aid of the microscope. By this means alterations may be found in the bloodvessels; and other minute changes can be discovered which will fully account for the fatal result.

DR. T. JOHNSON ALLOWAY reported a case of epilepsy, due to syphilis, cured by large doses of potassium iodide.

THE PRESIDENT (Dr. Roddick), after relating some cases of brain syphilis he had seen, said that he thought a history of gonorrhœa is, in many cases, quite sufficient to establish the fact that syphilis had been contracted, as chancres may occur in the urethra, and so cause a discharge which simulates gonorrhœa. Many of these cases, when there is no history, may be instances of late development of hereditary syphilis. He had seen such a case, with Mr. Jonathan Hutchinson, in London, a couple of years ago.

Digitized by Google

DR. ROSS, in reply, said that pain in the head, although a prominent symptom in his cases, he should by no means always expect to find. No one symptom is pathognomonic of cerebral syphilis; but pain comes near to being so, especially if it be nocturnal. Many cases are most obscure, and no history of syphilis can be obtained.

CORRESPONDENCE.

THE WASHINGTON MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

(*From our Own Correspondent.*)

THE American Public Health Association has just been holding its Thirteenth Annual Session in the City of Washington. This was, perhaps, the most representative meeting the Association has ever held. Among its members were nearly all the chief active sanitary officers of State and Municipal Health Boards, with representatives of the Army, Navy, and Marine-Hospital Service. They are generally men of large experience and earnest convictions, who are acquainted with the details of sanitary administration and who have found it necessary to keep abreast with advancing knowledge. The long autographic letter of the President of the United States showed an appreciation of public health interests very gratifying to those laboring in this cause. Maine and Pennsylvania with their new State Boards, and North Carolina with a large appropriation in place of suspended work, were warmly welcomed.

While appreciative of the Association, we have sometimes criticised it because it devoted so much time to popular addresses and exhortations, and not enough to that class of papers and discussions which have to do with scientific progress, and with the technical methods of administrative work. There are many things which we no longer need be told ought to be done—what we need to know, is just how to do them. There were at least four groups of papers that concentrated in this direction: the first was the series having reference to nomenclature and statistics. Dr. Hunt, of New Jersey, reviewed the terms now in use in the various departments of public and State hygiene, and showed that not a few needed to be used more precisely, while others should be retired from service. He offered an outline, and quoted authorities and reasons therefor. Some of the changes proposed were the use of the term State Hygiene instead of State Medicine, of communicable instead of zymotic and other terms; the use of infectious—if at all—only as the synonym of communicable, and the arrangement of miasmatic, contagious, contagio-miasmatic and malarial diseases as classes under that order. The statistical nosology was also reviewed. The parasitic diseases, microörganisms, or microbia, should be the only general terms; microzoöic serving to designate such as are of the animal, and microphytic such as are classed with the vegetable kingdom. Thus bacteria, bacilli, micrococci, and spirochætæ, serve to designate groups so far as known under the microphytes, while Cobbold furnishes us the details as to the microzoa.

Dr. Billings reviewed the modes of tabulating vital statistics, and showed how these tables are best prepared, and, where choice must be made, what ones should be preferred. He illustrated the subject by his experience with the returns of the last Census, and showed the need of greater uniformity.

Dr. Baker, by statistics and curves, set forth the evidences of the relation between rainfall and ground-water level in cholera, as he has before done as to typhoid fever.

Dr. Chancellor, of Maryland, discussed the evidences that consumption is largely caused by impure air and unhealthy occupations. The statistics were from good sources, but we regret that no accurate American statistics could be furnished. The discussion drew out some valuable distinctions between those pulmonary diseases that result from impure air and those that result from particles of mineral or other matter. These latter are too frequently called phthisis. The paper of Dr. Lee, of Philadelphia, deserves to rank with this group because it not only figured out the cost of the Plymouth epidemic, but with accuracy of detail associated the water distribution and the specific dejecta of typhoid fever originating in Philadelphia with the more than eleven hundred cases that occurred.

The next group was occupied on matters of administrative hygiene. Dr. Rauch, of Illinois, Dr. Holt, of New Orleans, and Dr. Armstrong, of the Marine-Hospital Service, in great variety of style and method traversed the whole subject of quarantine. It was urged that *Manner or Method*, and not *Time*, is the question. Dr. Holt is following out the plans of the New York Quarantine and of Dr. White, and other of the Auxiliary Association, those of New Orleans. Only in common with these he has learned that examination and disinfection must be radical, that superheated steam is better than fumigation, although this may be added, and that corrosive sublimate is valuable. It is not creditable that we should have been so long finding out what Humphry Davy told us long ago and saw applied in the art called kyanizing. The modes of opening up the hold of a ship and dealing with bilge water were shown. Dr. Rauch's paper was historical, and that of Dr. Armstrong, a detail of methods. The papers and discussion serve to put on record the accepted methods, valuable not less to commerce than to sanitation. We hope, however, that in the volume a few abridgments will be made. The reports from Canada as to smallpox and the particulars of its management were very interesting and instructive. Dr. Bryce represented chiefly the Province of Ontario. Dr. Hingston not only detailed the facts as to the more than 3000 deaths and the unnumbered cases of smallpox in Montreal and vicinity, but in a forcible manner illustrated the crime of those who incited the French populace to resistance. Vaccination scored many a valuable record, although some gentlemen made statements about manufactured vaccine and recurrent smallpox which they failed to substantiate.

Dr. Wright read a paper on his experience at Detroit in the disinfection of sewers with sulphur. His descriptions were graphic, his plan inventive and his comments decidedly forcible. It certainly showed thorough work, although some of his conclusions as to its effect in arresting scarlet fever and diphtheria were questioned. The sulphur got into so many houses as to satisfy the occupants of the imperfection of their traps. A Cleve-

Digitized by Google

land plumber made some excellent remarks on the need of skilled oversight in all house-pipe construction.

The Report of the Committee on School Hygiene and the excellent comments of Hon. Erastus Brooks on the twenty or more papers submitted to his committee on the Lomb Prize on this subject, were very valuable as permanent contributions. Not less so was the paper of Prof. Hartwell, of John Hopkins University, Baltimore, on "The German System of Physical Education." All these contributions were historical and critical, and with the essay of Dr. Lincoln, of Boston, who received the Prize, furnish the best material on school hygiene ever produced in this country. The work of sanitary school inspection now found to be going on in several of the States is most important.

The Report of the Committee on Disinfectants has already been, for the most part, before your readers. In addition, Surgeon Stanbery received the prize for a distinct essay on the subject. This report has not been too much commended. Yet now that it is before the Association some of its methods and conclusions will come under review. It should be read side by side with the work of the Local Government Board of England for the past two years.

The Association now feels that it has advanced in the direction of scientific research, and set itself at work in two or three other directions for the next year. As throwing additional light on the biological investigation of disease and the mode of its prophylaxis, the paper of D. E. Salmon, D.V.S., on "The Swine Plague," was equally valuable.

Of the four Lomb Prizes, two have been already alluded to. Second prizes only were given on "Healthy Homes and Foods for the Working Classes," and on the Preventable Causes of Disease, Injury, and Death "in American Workshops." The first was secured by a physician of Ann Arbor; the second by a mechanic (we believe), of Springfield, Massachusetts. Both are valuable. The Committees were very exacting, and determined that the essays to be distributed broadcast throughout the land should have real merit. Three first prizes remain unawarded. Captain Lomb, of Rochester, not only continued these for another year, but added additional prizes for a working plan and model for artisans' houses of prices $1500, $1000, and $600, and for a tenement house for about fifteen families, complete in all sanitary appointments.

Other papers, such as those of Dr. Morris, of Baltimore, on "Cremation," Dr. Bell, of Newport, on "Hygiene of the Dwelling," Dr. Wood, of North Carolina, on a "Study of Southern River Water," Dr. Hargis, of Pensacola, on "Modified Inoculation," etc., deserve mention. The Association now commands the attention and coöperation of physicians, engineers, chemists, teachers, plumbers, and the public, and has had a four days' conference of great advantage to its members and the country at large.

The address of its President, Dr. Reeves, of West Virginia, was worthy of the occasion. In Dr. H. P. Wolcott, of Massachusetts, he has a worthy successor. If the Executive Committee will condense the material into a portable volume and provide for a separate dissemination of the Lomb Prize Essays, it will do a better work for sanitary progress than has ever yet been done in any previous year in the United States.

RUPTURE OF THE VAGINA.

To the Editor of THE MEDICAL NEWS.

SIR: I wish to report, in addition to those mentioned recently in THE MEDICAL NEWS, another case of vaginal rupture which occurred in a girl nineteen years of age, as the result of coitus. The same man had had intercourse with her once before and, with the exception of considerable pain, without any bad result. This time, however, the pain was very severe and the act was followed by a profuse hemorrhage, which still continued when I saw her eighteen hours after. I found her in a bed which was soaked in blood. She was very anæmic, much exhausted, and had a weak, rapid pulse. On examination, I found no bleeding at the hymen, but about one inch beyond, on either side, were several longitudinal fissures, from half an inch to an inch in length, from which the blood was oozing at the rate of a teaspoonful in two minutes (vaginal distention by the speculum probably increased the flow to some extent). The bleeding was stopped by packing the vagina with tampons saturated with liq. ferri subsulphatis.

GEO. E. THOMPSON, M.D.

BOSTON, December 2, 1885.

NERVE STRETCHING IN THE TREATMENT OF SCIATICA.

To the Editor of THE MEDICAL NEWS.

SIR: In THE MEDICAL NEWS for January 10, 1883, page 10, I reported a successful case of nerve stretching for the relief of sciatica, performed at the Boston City Hospital by Dr. Fifield. The man has since remained entirely well, though the condition of his life has been most favorable for a recurrence, as he is now a common drunkard and tramp. As more than three years have now elapsed since the operation, the cure may, I think, be considered permanent.

Very truly yours,

ROYAL WHITMAN, M.D.

BOSTON, 93 BOYLSTON STREET,
December 12, 1885.

OBITUARY.

ALBERT H. SMITH, M.D.

IT is with heartfelt sorrow that we record the death of Albert Holmes Smith, one of the best known and most highly esteemed of Philadelphia physicians. This sad event occurred, after months of painful illness, on Monday morning, the 14th of December.

Albert H. Smith was born in Philadelphia, July 19, 1835, his father being the late Dr. Moses B. Smith. He was educated in the Friends' School at Westtown, and in the University of Pennsylvania, graduating in the Department of Arts in 1853, and in medicine in 1856. His preceptor was the late Dr. George B. Wood. He began his professional work as an assistant physician in the Frankford Asylum, leaving this position, however, after eighteen months to enter the Pennsylvania Hospital as resident physician. In 1859 he was appointed assistant physician to the Philadelphia Lying-in Charity, and in 1862 one of the attending physicians, holding the latter position until nearly a year ago. In 1862 he

Digitized by Google

was appointed one of the obstetricians to the Philadelphia Hospital. He was one of the founders of the Philadelphia Obstetrical Society, and was its President from 1874 to 1876. He was President of the Philadelphia County Medical Society during the years 1880 and 1881. He was one of the founders of the American Gynecological Society, and was its President at the ninth annual meeting held last year. Some of his most valuable contributions to medical literature will be found in the various volumes of *Transactions* of this Society. His papers were usually of a practical character, and always enlisted the interest of intelligent physicians, even though they might not in every instance command ready assent. The following is believed to be a nearly complete list of his published papers:

A Simple Form of Inhaler for Ether (Amer. Journ. Med. Sci., April, 1869).

A Compact and Portable Obstetric Case (Amer. Journ. Med. Sci., July, 1869).

An Improved Speculum (Med. Press and Circular, Dec. 1869).

The Use of Pessaries in the Early Months of Pregnancy (Amer. Supplement to Obstet. Journ., April, 1875).

Quinia as a Stimulant to the Pregnant Uterus (Amer. Supplement to Obstet. Journ., June, 1875.

A Vulsellum for Using with the Écraseur (Medical Times, August 7, 1875, p. 709).

Retarded Dilatation of the Os Uteri in Labor (Med. and Surg. Reporter, August 11 and 18, 1877).

Use of Catgut in Gynecological Surgery (Med. and Surg. Reporter, 1878).

Application of the Rotating Burr for Denuding Tissues in the Restorative Surgery of the Female Pelvis (Trans. of the Amer. Med. Assoc., 1878, vol. xxix. p. 475).

Pendulum Leverage of the Obstetric Forceps (Gynecological Transactions, vol. iii., 1879).

The Uses of the Hot-water Douche in Parturition (Phila. Med. Times, August 16, 1879).

On the Use of Intrauterine Stem Pessaries (Proceedings of Phila. Co. Med. Soc., vol. ii., 1879–80).

Clinical Notes of a Case of Twin Pregnancy (Proceedings of Phila. Co. Med. Soc., vol. iii., 1880–81).

Relation of Cleanliness to the Prevention of Puerperal Septicæmia (Med. News and Abstract, Oct. 1881).

Sponge Tents (Med. Times, Feb. 25, 1882).

Axis Traction with the Obstetric Forceps (Gynecological Transactions, vol. vi., 1882).

Relation of the Phila. County Medical Society to the Profession and Community (Med. Times, Dec. 2, 1882).

Hot Water in Secondary Hemorrhage after Pelvic Operations (Gynecological Transactions, Sept. 1883).

The last paper Dr. Smith read before the Philadelphia County Medical Society was upon "Manual Examination in the Diagnosis of Pregnancy;" this paper was unfortunately not published.

He was the inventor of several instruments, among which may be mentioned a uterine speculum, and hard-rubber urethral dilators, and he made an important modification of Hodge's pessary which has received the approval of the profession at home and abroad; probably this simple but very useful modification of the pessary has made his name more widely known than all that he has written.

While one of the attending physicians of the Lying-in Charity, he lectured every year, not only upon obstetrics, but also upon nursing. The former lectures were in some years delivered to mixed classes, both male and female students attending them. But the most sensitive of women found no occasion to blush on these occasions by any utterance of their teacher, so refined and chaste was he in thought, and so wisely chosen were his words. Indeed, he held that no one in lecturing upon any medical subject ought to allow himself to say to male auditors that which he would be ashamed to say were women present. His lectures were prepared with great care, but only brief notes were used in their delivery; he was clear, simple, logical, and thorough in these instructions. The school in which he taught was founded by Dr. Joseph Warrington, who still lives at a very advanced age, and has been an important part in the obstetric teaching of Philadelphia in the hands of its illustrious founder, and in those of his successors. From Dr. Warrington Dr. Smith had derived his chief knowledge of practical obstetrics, and was true to the traditions of the school, and contributed much to its fame and usefulness.

Dr. Smith has for some years been justly recognized as one of the leading obstetric practitioners of Philadelphia, the profession and the people alike knowing his ability; he seemed to be nearing the zenith of his fame and usefulness, and there was apparent the promise of long life. But a few years since occasional clouds came across the bright outlook, sudden and severe attacks of illness, which an indomitable will and conscientious devotion to duty helped him to triumph over for the time, occurred, and possibly were the forerunners of the grave disorder which ended his life, the shadows of the cross which was so soon and so heavily to rest upon him. By the advice of some of his professional friends, in November, 1883, he made a visit to Sir Henry Thompson, for his diagnosis and treatment. In a few weeks he returned home somewhat improved and greatly encouraged, and immediately again engaged in active practice. Probably overwork, for Dr. Smith was a man who would not, or could not, spare himself when the sick asked his professional aid, hastened relapses, and his practice had many sad pauses when it was temporarily laid aside. Finally, about a year ago, he had to abandon attempts at work, indeed, was from that time bedridden most of the time, until death gave release from agonizing pain which tortured him by night and by day.

Dr. Smith died young; he had not completed half of his fifty-first year. The days of our years are three score years and ten, said the Psalmist; but Dr. Smith failed by nearly twenty years in securing his just allotment of time. Nevertheless, many a man may live much longer, so far as years are concerned, and accomplish much less than he did; in truth, it is granted to few men to live as noble and useful a life as did this hardworking, much-suffering Philadelphia obstetrician.

He was a wise practitioner, a skilful obstetrician, and a successful gynecologist. His surgical operations were marked by great deliberation, the utmost coolness, scrupulous attention to details, and conscientious regard to the interests of the patient.

As a consultant he was frank and honest, and held sacred the reputation and interest of his fellow-practi-

Digitized by Google

tioner; he would by no act or ambiguous utterance cast discredit upon him, and at the same time was careful that the interests of the patient should be properly regarded. He was kind to young physicians, and many of these in Philadelphia will mourn his loss as though he had been an elder brother who was their strength and defence, their wise councillor, and faithful friend.

The sick poor always found him attentive and kind; many an hour by night and by day did he spend at sick beds, when his only hope of reward was in the consciousness of doing good, and in the gratitude of those whom he healed of disease, or rescued from death.

He was a magnanimous man, incapable of the little jealousy which so often mars professional life; large-hearted, he tried to be charitable in opinion and conduct toward all others. He made no concealment of his opinions when their avowal was necessary, no matter whether those opinions met with popular professional favor or not; his individual conscience gave him a higher law than the strong passions of the day or varying prejudices of the hour.

Dr. Smith was not less remarkable for modesty than for magnanimity; his works, not his words, praised him. If one wished to know what important operations he had done, the information came not spontaneously, but in answer to direct questions, for he had this mark of true greatness, extreme reticence as to his work, while some men of less ability, and every way inferior achievements, would be ready to parade before the public, or pour into any listening ear the merest trivialities of their professional success.

During his long and very painful illness scarcely a day passed without many messages of kind inquiry and affectionate sympathy, presents of flowers or fruits, or calls, did temporary lull in suffering permit him to see visitors, from his devoted patients. No physician ever had truer friends in his *clientèle*—they made his sick room bright, so far as possible, with kind words and generous gifts; they were knit to him as if with hooks of steel—he was so kind, so good, so affectionate, so self-sacrificing, no wonder they loved him—he was for them indeed the beloved physician.

Dr. Smith's wife and five children, two sons and three daughters, survive him, now mourning an irreparable loss, a loss which human utterance cannot magnify, and which the largest human sympathy cannot lessen.

NEWS ITEMS.

THE PHILADELPHIA POLYCLINIC having outgrown its quarters at Thirteenth and Locust Sts., will, after the winter months, occupy its new building, Broad and Lombard, where it is expected to open wards and private rooms for patients needing treatment in bed.

The journal edited by the faculty will be increased in size after the first of the year.

THE ANNUAL REPORT OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—At the December meeting of the College, the standing committees presented their annual reports.

The Library Committee reported that the library now contains 33,686 volumes and 1393 unbound pamphlets, an increase in the year of 2592, as compared with 1261 in 1884, and 869 in 1883.

The books are classified as follows:

General Library	18,069
Lewis Library	8,736
On special deposit:	
Mütter Museum	86
S. D. Gross Library	5,130
The Hodge collection	1,665
Total	33,686

The library is in receipt of 184 current periodicals devoted to medicine and the collateral sciences.

The number of books taken out during the year, not including the large number which have been consulted in the rooms, was 1231. In the General Library all the books are catalogued, with the exception of the dictionaries, journals, reports, and pamphlets. In the Lewis Library, all the books are catalogued to date.

During the year additional bookcases were erected in the large hall, affording accomodation for about 2600 books. These cases are now full.

The Committee on Publication reported that during the year, papers had been read by fourteen Fellows. In addition to these a paper by Dr. Graham and one by Dr. Orville Horwitz, were communicated by Dr. J. M. DaCosta, and an address on Photography of the Larynx was read by Dr. Theodore R. French, of Brooklyn. The total number of pages in the volume of *Transactions for 1885*, to this date, is about 232. Through the generosity of the President, the committee had been enabled to employ a stenographer and thus obtain a full report of the discussions.

The Committee on the Directory for Nurses reported that the number of nurses registered December 1, 1884, was 419. The present number is 475, showing a gain of 56. During the year the loss by dismissal, resignation, death, and removal was 18. The number of applicants for registration was 118, of whom only 68 were registered. The largest number of nurses sent out in any one month, was in January 1885, 119; the smallest in August, 47. The total number of nurses supplied during the last four years has been in 1881–82, 342; 1882–83, 733; 1883–84, 913; 1884–85, 1003. Seventeen wetnurses were furnished during the year.

The Committee has recently assisted the New York Academy of Medicine in establishing a similar directory for nurses in that city.

RESIGNATION OF PROF. C. A. LINDSLEY, M.D.—PROF. C. A. LINDSLEY, M.D., has resigned the position of Dean of the Medical Department of Yale College, and Dr. Herbert E. Smith has been appointed his successor.

INTERNATIONAL HYGIENIC CONGRESS IN ROME.—We learn that the Italian Government has again postponed the meeting of the International Hygienic Congress. It is generally conceded that the Congress will not meet this winter.

SCIENCE AND CHIVALRY.—In a recent number of *L'Union Médicale*, under the head of correspondence, the following letter is published:

"Thorens has related the sad ending of a duel at

Digitized by Google

which he assisted. The wound caused pleurisy-empyema, and death ensued. Ought not we to recommend to the surgeons some precautions that one takes in every operation? We should demand that the foils be passed through a flame, or put in carbolic acid, and that the combatants as well as the surgeons should wash their hands in carbolic solution. The surgeons should have carbolic solution ready to apply to a wound at once. We should like to have the pistols and balls disinfected. One fights sometimes for reasons that so little affect one's honor that the precautions deemed necessary for the slightest operation should be taken. One sees that the blades are sharp; we demand that they should be clean, medically."—*Canadian Practitioner*, Dec. 1885.

RESOLUTIONS ON THE DEATH OF DR. SAMUEL S. CLARK.—The Board of Managers of the State Asylum for the Insane at Morristown, N. J., learn with the deepest feelings of sorrow, of the death of their honored Vice-President, Dr. Samuel S. Clark, which occurred at Belvidere, on Monday, the 23d ult.

Dr. Clark came of a distinguished ancestry, from whom he inherited those sterling qualities which made his life so useful and honored. His grandfather, Rev. Joseph Clark, left the pulpit to enter the Revolutionary army, and served with distinction on the staff of General Washington. His father, Rev. John Flavel Clark, was also a distinguished Presbyterian clergyman, and one of the founders of the American Board of Foreign Missions, and, subsequently, became one of the faculty of Princeton College. With such ancestry, it was but natural that Dr. Clark should be the noble man that he was.

He was born at Flemington, N. J., November 8, 1825, and entered Princeton College in 1841. After a three years' course in that institution, he entered and graduated from the medical department of the University of New York, and for nearly thirty-seven years practised medicine in Belvidere. His kindness of heart, his faithfulness as a friend, his wisdom as a counsellor, his tender sympathy and skill as a physician, endeared him to the homes and families in the rounds of his large practice.

His clear mind, his fine culture, his habits of careful study, and his acquaintance with the best results of science, placed him in the front rank of his noble profession. He was active and public spirited as a citizen, always promoting the best interests of the community in which he lived. As a member of the Board of Managers, he was firm in his convictions of right, yet considerate and forbearing with those who differed with him. Withal, he was modest and unassuming, and always a gentleman.

He was one of the most companionable of men, and his fine social qualities endeared him, not only to his associates in this Board, and to the masses with whom he came in contact, but to eminent men in all professions throughout his native State.

More than an ordinary man has fallen; a happy home has been made desolate and a devoted wife and daughter, upon whom his fondest affections were centered, mourn for one whose companionship was more precious to them than all other earthly treasures. We tender to them our deepest sympathy.

We record this tribute to his memory in our book of minutes, and request our Secretary to transmit a copy of the same to his sorrowing family.

BOYLSTON MEDICAL PRIZE QUESTIONS.—At the annual meeting of the Committee for 1885, it was voted that a prize of two hundred dollars be awarded to Edward S. Stevens, M.D., of Harveysburg, Ohio, for a dissertation on "The Best Preliminary Education for the Study of Medicine."

The following are the questions proposed for 1886:

I. Influence of the Soil as a Factor in the Causation and Spread of Typhoid Fever.

The author of a dissertation on the above subject, considered worthy of a prize, will be entitled to a premium of three hundred and fifty dollars.

II. The Relation of Hospitals to Medical Education.

The author of a dissertation on the above subject, considered worthy of a prize, will be entitled to a premium of two hundred dollars.

Dissertations on the above subjects must be transmitted, post-paid, to Morrill Wyman, M.D., 24 Church St., Cambridge, Massachusetts, *on or before the first Wednesday in April*, 1886.

The following are the questions proposed for 1887:

I. On the Identification of Human Blood in Suspected Stains.

II. Original Investigations on the Pathology of so-called Uræmic Symptoms.

The author of a dissertation on either of the above subjects, considered worthy of a prize, will be entitled to a premium of two hundred dollars.

Dissertations on these subjects must be transmitted as above, on or before the first Wednesday in April, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING DECEMBER 12, 1885.

LIPPINCOTT, GEORGE C., *Passed Assistant Surgeon*.—Detached from Navy Yard, Washington, and wait orders.

DEANE, C. W., *Passed Assistant Surgeon*.—Ordered to the U. S. R. S. "Dale," as relief of Passed Assistant Surgeon G. P. Lumsden.

LUMSDEN, G. P., *Passed Assistant Surgeon*.—Ordered to Naval Hospital, Washington.

LOVERING, P. A., *Passed Assistant Surgeon*.—Detached from U. S. R. S. "Wabash," and wait orders.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 8 TO DECEMBER 14, 1885.

EVERTS, EDWARD, *First Lieutenant and Assistant Surgeon*.—Ordered from Department of Columbia to Department of Arizona.—*S. O.* 279, *A. G. O.*, December 5, 1885.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING DECEMBER 12, 1885.

YEMANS, H. W., *Passed Assistant Surgeon*.—Granted leave of absence for fifteen days, December 7, 1885.

BRATTON, W. D., *Assistant Surgeon*.—When relieved to proceed to San Francisco, Cal., December 12, 1885.

NORMAN, SEATON, *Assistant Surgeon*.—Appointed an Assistant Surgeon December 11, 1885. Assigned to duty at New York, N. Y., December 12, 1885.

RUPTURE OF THE LIGAMENTUM PATELLÆ, AND ITS TREATMENT BY OPERATION.[1]

BY HENRY B. SANDS, M.D.,

PROFESSOR OF THE PRACTICE OF SURGERY IN THE COLLEGE OF PHYSICIANS AND SURGEONS; SURGEON TO THE ROOSEVELT HOSPITAL.

THREE forms of injury to the knee are closely allied by their causes, effects, and principles of treatment. These injuries are, simple transverse fracture of the patella, subcutaneous rupture of the tendon of the quadriceps extensor muscle above that bone, and a corresponding lesion of the inferior division of the tendon, known as the ligamentum patellæ. The experience I have gained in the management of two cases of the last-named accident which have fallen under my observation, has led me to a brief study of its literature, from which I have gleaned a few facts of sufficient interest, perhaps, to justify me in bringing the matter to the notice of the Society. At the same time I desire to put on record a number of cases of this injury hitherto unpublished, and to describe an operation for uniting the ends of the divided ligament by suture, which I have performed upon the patient now exhibited before you.

Compared with the fracture of the patella, rupture of the ligamentum patellæ is a rare event. Maydl,[2] whose statistics are the largest I have yet met with, was able to collect only sixty-five examples of the latter form of injury. In this paper I am able to report thirteen other cases treated in the Bellevue, New York, St. Luke's, and Roosevelt Hospitals. In order to form a rough estimate of the comparative frequency of the two forms of injury, I have caused a search to be made of the entire records of the four hospitals above mentioned, and have obtained the following result:

	Fracture of patella.	Rupture of ligamentum patellæ.
New York Hospital	150 cases.	3 cases.
Bellevue Hospital	140 "	7 "
Roosevelt Hospital	44 "	2 "
St. Luke's Hospital	19 "	1 case.
Total	353 cases.	13 cases.

A comparison of these figures gives a ratio of about twenty-five to one.

The relative infrequency of rupture of the patellar tendon may be ascribed chiefly to its great strength and thickness, its relatively slight exposure to direct injury, and to the great mechanical advantage with which indirect violence often acts in causing fracture of the patella. Thus, as has been remarked, when the knee is bent, and a sudden and powerful contraction takes place of the quadriceps extensor muscle, as in endeavoring to prevent the body from falling backward, the patella is acted upon by two forces which, as its upper and lower borders are then free from contact with the femur, may cause it to break, in the same manner as a stick may be broken by bending it across the knee.

The remarks which I wish to make may conveniently take the form of a commentary upon the cases which have come under my care, or which, as will be seen in the appended table, have been gathered from the hospital records above mentioned. I shall give only my own cases in detail.

CASE I.—Patrick F., a car driver, thirty-five years of age, was admitted to my department of the Roosevelt Hospital, October 19, 1882. Ten years previously his right patella had been fractured by striking his knee against the pole of a truck. Five months later the same accident recurred, the final result being a fibrous union between the fragments, which remained separated a distance of two inches. On the day of his admission into the hospital, while in the act of hitching his horses to a street car, he missed his footing in attempting to ascend the platform, and felt something suddenly give way. An examination detected evidence of an old fracture of the right patella, which had been broken about its middle. The distance between the fragments measured two inches, and the interval was occupied by a broad, thick, fibrous band. In the normal situation of the ligamentum patellæ was found a shallow depression, dependent upon a complete rupture of the ligament, which seemed to have been torn close to its inferior extremity. Patient entirely unable to extend the leg. Much tenderness and swelling of knee.

Treatment.—Extension of limb to horizontal position. Ice bag applied to knee.

Oct. 28.—Pain and swelling subsided; vertical suspension of injured limb; rubber bandage to knee.

Nov. 14.—Apparatus removed; limb kept extended, and raised on a pillow. The gap below the patella has filled up.

Dec. 3.—Waterglass bandage applied from ankle to thigh. Patient allowed to walk.

7th.—Discharged from hospital, wearing splint.

Nov. 21. 1885.—Patient reëxamined three years after injury. He states that, disobeying the instructions he had received on quitting the hospital, he removed the splint a few days afterward, and began to use the limb more freely. His knee remained stiff, however, until five weeks later, when, in descending a staircase, and being within two steps of the bottom, he imagined he had reached the end; and, putting forward his left foot, a strain came on his right knee, which was suddenly and forcibly bent. Some pain followed, and he thought he was severely hurt; but the next day he discovered that

[1] Read before the New York Surgical Society, Dec. 8, 1885.

[2] Zeitschrift für Chirurgie, vols. xvii. and xviii., 1882 and 1883.

Digitized by Google

he was better, and that he could readily flex and extend the leg. At present, as he is now exhibited before you, he can flex it a little beyond a right angle, and can make complete extension with some force. He says he is not aware of any difference in the strength of the opposite limbs. Separation of patellar fragments two inches. Length of ligamentum patellæ same on both sides.

Evidently, in this case, the rupture of the ligamentum patellæ was due to the severe strain to which it had been subjected by the weight of the body, and the forcible contraction of the quadriceps extensor muscle. Whether transverse fracture of the patella usually results from direct or indirect violence is an open question. I agree with those, however, who contend that this injury may generally be traced to the latter cause; and I am sure that the same is true regarding rupture of the ligamentum patellæ. Madyl, in investigating the etiology of this accident, analyzed 44 cases, in only 5 of which the rupture could be attributed to direct violence. Most often it is occasioned by a powerful contraction of the quadriceps, occurring in an attempt to save the body from falling backward; at other times, from falling forward or sidewise. Violent flexion of the leg, accompanying a fall from a height, may produce it; and it has been known to occur spontaneously during an attack of convulsions, as also during forced flexion practised with the object of overcoming an anchylosis of the knee. In the last case muscular contraction cannot be concerned in the rupture, which must be ascribed in part to pathological changes in or around the affected joint. Adhesion and fixation of the patella, or rigidity and contracture of the quadriceps muscle, may, by preventing the descent of the patella when the knee is bent, cause the ligamentum patellæ to be lacerated during forcible flexion, either manual or instrumental.

In some of the cases I have collected from our hospital records, the agency of muscular contraction in causing the rupture is plainly evident. The case just narrated (X.) is one in point. In another case (IV.), the man, while wrestling, was thrown down, striking the left knee. As he fell, he was conscious that something had given way; and on trying to get up, he found himself unable to extend the right, or opposite, leg. Another man (VII.) stumbled while carrying a barrel of flour; and in a violent but unsuccessful effort to save himself from falling forward, heard something snap and felt his knee suddenly give way as he came down with his left leg helpless. Another (VI.), whose heel had been caught between two flagstones, and who squatted quickly to pick up his hat, felt something give way, and immediately fell to the ground, unable to extend his legs. In this case the rupture occurred on both sides. In Case XIII. the man slipped while crossing the street, and did not strike the knee. In Case XII., to be related presently, the injury was certainly due to direct violence, a heavy piece of timber having fallen across the knee. One patient (IX.) fell from a roof, sustaining fracture of the left thigh and rupture of the left ligamentum patellæ. Here the violence may have been direct, as also in Case II., in which a sailor fell from a jibboom a distance of thirty feet, striking his knee; and in Case XI., in which a fireman was buried beneath a falling building, and, on being extricated, was found to have received a fracture of the femur, a rupture of the ligamentum patellæ, and severe contusion of the injured limb. In Case I. the patient fell from a wharf into the water, hitting his knee against a boat. Whether, in the four cases last described, the rupture of the ligament was caused by direct injury, by extreme flexion of the knee, or by muscular contraction, must be a matter of doubt; and, in the remaining examples, the doubt concerning this point must be still greater. Thus, one man (V.), while engaged in carrying a plank, fell upon his left knee; another, who was assaulted and knocked down in front of his lodging house, struck his knee against the doorstep. In Case III., the patient, while walking, stumbled and fell, striking his knee against the ground. Now, in all these cases, the circumstance that the knee was hit seems to favor the supposition that the rupture was occasioned by direct violence. But it is quite likely that such an inference would be wrong, and that the fall upon the knee may have been the result, not the cause, of the rupture. This explanation is corroborated by the probability that, in all these instances, the extensor muscles were forcibly contracted at the moment the accident happened.

It is well known that rupture of the ligamentum patellæ is far more frequent in the male than in the female sex. I have been unable to find more than five published cases in which females have sustained this injury, and the thirteen subjects, whose cases I have recorded, were all males. The relative frequency of the accident in the latter may be accounted for by their greater exposure to its exciting causes, and by the greater strength and activity of their muscles.

In one case (VI.), already mentioned, the rupture took place on both sides simultaneously. Four other cases of this double injury have been recorded, namely, two by Shaw,[1] one by Gibson,[2] and one by Hamilton.[3] In three cases (III., VII., X.), the rupture occurred in persons who had previously suffered from transverse fracture of the patella on the same side. In Case III. the patella had been broken one year previously, and ligamentous union had taken place. In Case VII. the fracture occurred eight months before the rupture, and the uniting band measured two inches in length. In Case X. the fibrous band was likewise two inches long, while a period of ten years intervened between the fracture and the rupture. I have found elsewhere only four other examples of this singular sequence,[4] from which, I think, two conclusions may be drawn. The first is, that a fracture of the patella may establish a predisposition to rupture of the ligamentum patellæ. In Flower's case, in which the rupture took place at the patellar attachment, this end of the ligament seemed to have ossified during the repair of the fracture; and to this

Digitized by Google

circumstance he was inclined to ascribe the predisposition. Such could not have been the explanation, however, in Markoe's case (III.), nor in the one I have reported (X.), as in both of these there was no evidence of ossification of the ligament, which, moreover, was found to be ruptured at its tibial insertion. In the majority of instances, probably, the essential cause of the predisposition is a weakness of the limb induced by the earlier injury, which renders the individual less able to avoid the accidents that determine the later one. The second inference is, that the fibrous bond of union between the fragments of a broken patella may be able to bear a greater strain than the normal patellar ligament. This may be the fact, even when the uniting band is of considerable length, as in the two cases I have recorded. Additional evidence of the occasional strength of the ligamentous union of patellar fragments is afforded by the numerous examples of refracture of the patella in which the second fracture has taken place through a part of the bone hitherto uninjured. It is noteworthy that, when rupture of the ligamentum patellæ has been preceded by fracture of the patella, the two lesions have always been found to exist on the same side of the body. The longest recorded interval between the two accidents is ten years, in Case X.; the shortest, eleven weeks, in Flower's case.

In seven of the cases I have reported, the seat of rupture is definitely stated. In three it took place at the upper, and in four at, or near, the lower attachment of the ligament. In two cases a small fragment of the patella was torn off; in one of these it could be distinctly felt, and in the other it gave rise to occasional crepitus when the ruptured parts were approximated. These results are in accordance with the general rule, that the ligament is far less liable to give way in its middle than at one of its extremities—the lower being involved in about 50 per cent. of all cases. The rupture, wherever it occurs, is usually complete; my notes of thirteen such cases furnish only a single instance in which a portion of the ligament remained intact.

The symptoms were in every case so plain as to leave no doubt concerning the nature of the injury. In one, the amount of retraction of the patella is said to have been slight; in another, it was two inches; but in all the gap between the severed parts could be distinctly made out. Prominent among the symptoms is inability to extend the leg. So far as I know, this loss of power is absolute when, as is usual, the rupture is complete. In transverse fracture of the patella, on the other hand, it occasionally happens that some power of extension remains immediately after the accident. An illustration of the preservation of this function to a remarkable degree came to my notice a few weeks ago, when a gentleman entered my office to consult me about an injury to his knee, which he thought he had sprained a few hours previously while playing in a tennis court. In the meantime he had been able to walk, and had gone down town to the stock exchange, and returned in a street car without suspecting the gravity of his injury, which, to my surprise, I found, on examination, to be a transverse fracture of the patella. The fragments, however, were in contact, and bony crepitus was well marked. We can readily understand why no such exception should ever be met with when the ligamentum patellæ is completely ruptured, since, under these circumstances, nothing is left to transmit the force exerted by the quadriceps, except the insignificant aponeurotic attachment of a few of its fibres to the tibia.

The condition of the knee-joint was noted in six cases, and, in all but one, the joint is said to have been distended and painful soon after the accident. Whether, as seems probable in this form of injury, the laceration extends into the joint, and whether the distention of the latter is due to the presence of blood or of inflammatory effusion, are points which have not yet been demonstrated. In any case, the swelling generally subsides, under appropriate treatment, in the course of a week or ten days.

The treatment adopted in most of the cases herewith reported was essentially the same as that usually followed in fracture of the patella, comprising extension of the knee, elevation of the injured limb, cold applications to the joint, and the use of pads, straps, and bandages for the purpose of approximating the ends of the ruptured ligament. As in the case of fracture of the patella, the retraction of the upper end appears to be largely owing to distention of the knee-joint with fluid; and, until this has been absorbed or otherwise got rid of, any attempt to force it downward will prove futile, and perhaps injurious. In one case (III.) in which compresses and tight bandages were employed very early, they certainly caused an aggravation of the symptoms, which compelled a suspension of this part of the treatment for a period of four weeks. The final result, however, was satisfactory.

As a rule, such treatment as that described is followed by a fair amount of recovery of the functions of the injured limb. I regret that the notes of some of the cases I have collected are so defective regarding the results obtained as to possess little or no value. We know, nevertheless, that the continuity of the ruptured parts is usually restored in the course of six or eight weeks, the knee meanwhile gradually regaining its normal size and shape. Afterward the joint generally becomes movable, and the power of extension returns to a variable degree. Occasionally both the physical and functional results are excellent, as in Weir's case (XIII.), in which, sixteen years after the injury, no difference could be discovered by measurement between the length of the patellar ligaments of the opposite sides, and in which the patient declared that the limb injured was quite as good as its fellow. Such a result, however, is exceptional, and the patella is apt to remain permanently more or less retracted, sometimes to the extent of several inches. Generally, as after fracture of the patella, the impairment of the power of extension bears a direct ratio to the length of the fibrous band by which the severed parts are united; but this rule is not without exceptions. A case has been recorded in which a lengthening of six centimetres did not prevent complete voluntary extension of the leg; on the other hand, the power of extension may be seriously impaired, even when the uniting medium is short and firm. Here the disability is doubtless owing

Digitized by Google

to some complication or sequel of the rupture, such as chronic inflammation of the knee-joint, atrophy of the quadriceps muscle, or adhesions between the opposed surfaces of the upper part of the synovial sac which lies underneath the quadriceps. In such cases flexion, as well as extension, is usually limited.

It is impossible to determine in what proportion of cases the power of extension is greatly damaged; but the number is larger than one would infer from a perusal of the published reports, in which very inferior results are often put down simply as "cures." We may be sure, however, that in a certain number of instances in which no union takes place between the ruptured parts, the power of extending the leg will be entirely abolished, and the act of walking rendered impossible without assistance. Hitherto such cases have been treated by some form of mechanical apparatus designed either to prevent the knee from being bent, or to make artificial extension by means of an elastic force; but, so far as I am aware, no attempt has been made to reëstablish the function of extension by an operation intended to restore the continuity of the ruptured ligament. Maydl states that, in a posthumous work by Veslingius (*Obs. Anat. et Posthum.*), published 1740, he found a notice of a case in which tenorraphy of the ligamentum patellæ was performed with success. He does not say, however, whether the injury was old or recent, and I have been unable to procure a copy of the work to which he alludes. In the case of the patient now exhibited I operated eight months after the accident, by bringing together the separated ends of the ruptured ligament, and uniting them by sutures. The history reads as follows:

CASE II.—Charles K., a healthy man, forty-four years old, by occupation a rigger, was admitted under my care in the Roosevelt Hospital seven months ago, and gave the following history. In September, 1884, a heavy piece of timber fell across his right knee, and he was at once disabled and could neither walk nor extend the leg on the injured side. The accident occurred at sea, and the patient received no treatment beyond confinement in bed on account of pain and swelling of the knee. In December he entered a hospital in Calcutta, where the joint was incised to allow the escape of fluid. He recovered from the operation, but remained as weak in the knee as before, being unable to walk except when he wore a splint applied to the back of the limb in order to keep it straight. When he came under my charge he was still wearing a leather splint, which, although apparently well suited to its purpose, did not render locomotion easy. The gait was slow and unsteady, and the patient, otherwise in good health, was greatly discouraged in consequence of his infirmity, and declared his willingness to undergo any operation in the hope of regaining the usefulness of his limb. On examination the right knee was found to be tender on pressure, and moderately swollen from an accumulation of fluid in the joint. The patella was displaced upward about two inches; it was freely movable laterally, but could not be drawn down to its normal position. Above, its relations with the quadriceps could be readily distinguished, but below, it evidently had no connection with the tibia.

As nearly as I was able to ascertain, the ligamentum patellæ had been completely ruptured close to its inferior point of attachment, and no attempt had been made to repair the injury. In place of the ligament there was a gap into which the skin could be readily depressed until the fingers encountered the femoral condyles. The power of extending the leg was entirely absent, and the patient, when lying upon his back with his legs extended, was unable to raise his foot from the bed.

On May 19th last, I commenced an operation by making a longitudinal incision, six inches in length, in the median line on the anterior aspect of the knee, the centre of the incision being opposite the lower edge of the patella. The cut was subsequently lengthened both upward and downward until it measured nine inches. On exposing the injured parts, in doing which the knee-joint was freely opened, it was found that the ligamentum patellæ had been torn away from the spine of the tibia, which was now covered by only a small amount of dense fibrous tissue, sufficient, nevertheless, to allow a firm hold for sutures. A little more than an inch of the ligament, in good condition, was normally attached to the patella. There was a complete lack of union between the ends of the severed ligament, and a great deal of difficulty was experienced in bringing them together after they had been freshened with the knife. Before the upper end could be drawn down and placed in contact with the lower one, it became necessary to make many deep oblique and transverse incisions into the median and lateral portions of the quadriceps; and even when this had been done as far as was deemed prudent, considerable force was required to secure apposition, which was maintained by two sutures of stout silver wire, the ends of which were twisted, cut short, bent flatwise, and buried in the wound. The mucous and alar ligaments were found redundant, and were partly removed with the curved scissors. The incisions in the capsule of the joint were closed by catgut sutures, and the external wound was united, except at its upper and lower ends, in the same manner. Two bone drains, one on each side, were inserted into the joint through openings made for that purpose, and one into each extremity of the median incision. During the operation a solution of mercuric bichloride, 1 : 1000, was applied freely to the wound, which was afterward covered with iodoform gauze. The limb was next enveloped in a moss-bag, moistened with the bichloride solution, and finally fastened to a long straight wooden splint, provided with a foot piece. Previous to the operation the knee and adjacent parts had been shaved, scrubbed several times with soap and water, then washed with oil of turpentine, and finally disinfected with a solution of mercuric bichloride.

The subsequent progress of the case was uneventful, except that, during the first four days, the patient complained of almost constant pain. This was so severe on the second day that I removed the dressing and examined the wound, which, however, showed nothing which would account for the man's suffering.

Digitized by Google

The drainage-tubes were cleared of a few clots of blood, and a fresh dressing like the first was applied. On the fourth day the pain began to diminish, and soon afterward it disappeared altogether. The wound was not dressed again until July 7th, seven weeks after the operation. It was then discovered that the wound had long before healed by primary union, except at its lower angle, where a minute skin ulcer remained, marking the site of one of the drainage-tubes. The wounds made for draining the joint were entirely closed. The patella was movable, as was also the knee-joint; but no attempt was made to bend the leg beyond a few degrees. On July 21st the patient was allowed to get up, wearing a water-glass bandage. This could not be worn with comfort, and, a week later, was replaced by a leather splint, with which the patient walked about without much difficulty. He continued to use the splint until October, when he laid it aside. Meanwhile the knee has assumed nearly its natural size and shape, and it is evident that continuity of the ruptured parts has been reëstablished.

My house surgeon, Dr. George S. Huntington, has, at my request, furnished me with the following precise description of the patient's present condition, which can be verified by the members of the Society:

Measurements.—Thigh: Circumference at upper border of patella, right thigh 13¾″, left thigh 14″; circumference at junction of middle and lower third, right thigh 13¼″, left thigh 15¼″.

Knees: Circumference of knee-joint over the patella, on both sides 13.9″.

Leg: Circumference at junction of upper and middle third, right leg 12¾″, left leg 13″; distance from tip of internal malleolus to lower border of patella, right side 15.6″, left side 14.4″.

Functional Result.—A line drawn from the middle of the upper border of the great trochanter to the centre of the outer surface of the external condyle is taken as the axis of the thigh. The axis of the leg is represented by a line drawn from the tip of the external malleolus to a point just anterior to the superior tibio-fibular articulation. On the left side in full extension of the leg, these lines form with each other an obtuse angle of 174°. On the right side, when patient is in the recumbent position, the amount of voluntary extension is as follows: The axis of thigh and leg forming an obtuse angle of 148°. When the patient is in a sitting posture, the amount of extension is increased to 155°.

Passive motion: Extension of leg possible to the normal limit. Flexion to a right angle. Rotation of the leg the same on both sides.

I will add that, in walking, the patient can easily and completely extend the leg: that for several weeks past he has been able to go up and down stairs without assistance; and that his limb is so steadily gaining in strength and freedom of action as to warrant the hope of further improvement. At all events, I think it will be admitted that, in this case, the operation has conferred a great benefit upon him by restoring the usefulness of the limb; and that, in similar cases, suturing of the ligament deserves a further trial. The principal difficulty likely to be encountered, when the injury is not of recent date, is that of bringing into contact the ends of the ruptured ligament. In my case this was accomplished only after the rectus and the vasti muscle had been extensively scored, and even then the parts could not be brought together without decided tension. I am inclined to believe that the pain the patient complained of during the first four days after the operation was caused by the traction of the sutures, and that it was relieved only when the sutures had cut through and receded far enough to moderate the existing tension. And, although I neglected to note the level of the patella immediately after the operation, its present elevation may be held as proving that the segments of the ruptured ligament separated from each other to a considerable extent after they had been sutured, the gap so formed being now occupied by newly formed ligamentous tissue, like that which, in ordinary cases of this injury, is furnished to repair it.

That which has most interested and gratified me in this and in several other severe operations I have performed, in which the knee-joint has been involved, is the impunity with which this articulation may be opened, and indeed somewhat roughly handled, provided antiseptic precautions are scrupulously observed. This fact was especially forced upon my attention in a case of old fracture of the patella, in which I wired the fragments, one year ago, in the Roosevelt Hospital. The operation was performed in the usual manner, but the fracture was found to have been comminuted, and the fragments could not be brought into apposition without much difficulty, nor until the quadriceps muscle had been extensively exposed and repeatedly cut, in order to obtain the necessary elongation. Meanwhile, the bleeding was free, the knee-joint was frequently sponged out and irrigated, and the operation was prolonged, as well as severe; yet the patient recovered without an unpleasant symptom, under the use of a single dressing; and when this was removed, at the end of eight weeks, I discovered that the wound had healed throughout by the first intention, and that neither suppuration nor adhesive inflammation had taken place within the joint, which had a limited range of easy motion. Such a case affords, according to my judgment, indubitable proof of the marvellous improvements in operative surgery which have been wrought by antiseptic methods; and, when I see it stated in a standard American text-book, published only three months ago, that "the alleged superiority of the antiseptic method cannot be said to have been as yet demonstrated," I am amazed at the author's incredulity. Even among those who practise antiseptic surgery, however, some hesitation is occasionally felt about opening the larger joints, and operations involving the healthy knee-joint are at present regarded by many with the same kind of apprehension which, not a great many years ago, deterred surgeons from invading the peritoneal sac. The latter procedure is, as we now know, reasonably safe, and I cannot doubt that the operation of opening the knee-joint is already, when properly performed, far safer. I confidently anticipate the time when skilful and careful surgeons will be able to divest it of all danger either to life or limb; and,

Cases of Rupture of the Ligamentum Patellæ.

No.	Hospital.	Age and sex.	Date.	Observer.	Side of rupture.	Cause.	Condition.	Treatment.	Results.
1	New York.	32, M.	1844	.....	Right.	Fall from a wharf into water, striking knee against a boat.	Joint much swollen; rupture at patellar insertion, carrying away a minute fragment of bone; patella not much retracted, and easily brought down.	Leeches, poultices, low diet; at end of ten days pads and straps.	Firm union; discharged "cured" at end of four months.
2	New York.	26, M.	1854	Watson.	Right.	Fall, thirty feet, striking knee.	Rupture of ligament just above tibial insertion: joint distended and painful.	Extension, cold lotions; crutches after four weeks.	Discharged "cured" at end of two months.
3	New York.	32, M.	1859	Markoe.	Left.	Slipped and fell, striking left knee.	Marks of fracture of patella sustained a year previously; fragments united by ligament; patellar ligament ruptured at tibial insertion; joint greatly distended and painful.	Single inclined plane; evaporating lotions; compress and bandage, which had to be removed on account of pain; reapplied four weeks later.	Discharged eleven weeks after accident, with firm union.
4	Bellevue.	60, M.	1870	Hamilton.	Right.	While wrestling, was thrown on left knee, and felt something give way; on attempting to get up, was unable to extend right leg.	Ruptured ligamentum patellæ.	Plaster-of-Paris bandage; figure-of-8 bandage to knee.	
5	Bellevue.	40, M.	1874	.....	Left.	While carrying a plank, patient fell, striking left knee.	Complete rupture of ligament; patient unable to stand or to extend leg; no pain or distention of joint.	Plaster-of-Paris bandage day after accident; renewed three times, and finally removed at end of six weeks.	Ligament united to tibia; knee somewhat stiff when patient was discharged eight weeks after injury.
6	Bellevue.	50, M.	1874	Wood.	Both.	Patient, whose heel had been caught between two flagstones, squatted quickly to pick up his hat, felt something give way, and fell to the ground helpless.	Each patella retracted from rupture of ligament; any extension of legs absolutely impossible.	Commenced seven months after injury; posterior splint, figure-of-8 bandage.	Left hospital a fortnight after admission; result not known.
7	Bellevue.	22, M.	1874	.....	Left.	Patient while carrying a barrel of flour, stumbled and made a powerful effort to save himself from falling forward; heard something snap as he fell; found left leg helpless.	Signs of old fractured patella eight months previously; firm fibrous union two inches in length; immediately below patella a groove corresponding with ruptured ligament.	Posterior splint.	
8	Bellevue.	52, M.	1878	S. Smith.	Left.	Was knocked down, striking knee against doorstep.	Much swelling and effusion in joint; rupture of ligament close to its attachment to patella.	Posterior splint; ice bag; afterward figure-of-8 bandage, and traction with adhesive plaster.	Patient discharged with stiff knee eight weeks after injury.
9	Bellevue.	10, M.	.....	.....	Right.	Fall from a roof.	Fracture of left femur; rupture of right ligamentum patellæ, incomplete, a few fibres only remaining intact.		
10	Roosevelt.	35, M.	1882	Sands.	Right.	Slipped while getting on a street car, and felt something give way.	Marks of old fracture of patella; fibrous uniting band two inches long; ligamentum patellæ ruptured near its tibial insertion.	Ice bag; extension, at first horizontal, afterward vertical; rubber bandage.	Recovery, with useful limb.
11	Bellevue.	34, M.	1884	Dennis & Bryant.	Left.	Buried beneath a falling building.	Rupture of ligamentum patellæ; fracture of lower third of femur; severe contusion of limb.	Double inclined plane for thirteen days; Buck's extension twenty-five days; plaster-of-Paris bandage six weeks.	Two years after injury patient has a stiff knee with the leg extended; flexion easy to the extent of 5–10 degrees, where it is suddenly checked, apparently in consequence of adhesion and shortening of the quadriceps at seat of fracture. Ligamentum patellæ reunited and firm, being lengthened only ½ an inch. Patella movable laterally, but not downward. Contraction of quadriceps causes no tension of ligamentum patellæ.
12	Roosevelt.	44, M.	1885	Sands.	Right.	Blow from a heavy piece of timber.	Eight months after accident power of extension entirely lost; patella retracted two inches; a depression in place of ligamentum patellæ which seems to have been ruptured near tibial attachment.	Joint opened; ligament sutured	Six months after operation power of extension regained sufficiently to enable patient to walk with ease.
13	St. Luke's.	47, M.	1869	Weir.	Left.	Slipped while crossing street; did not strike knee; walked with assistance twenty or thirty feet after accident.	Rupture of patellar ligament.	Limb extended in plaster-of-Paris splint for six weeks.	Began to walk soon after removal of splint. Sixteen years later (1885) injured limb as good as other. Ligament same width and length as other by measurement.

whenever this period arrives, our time-honored, but clumsy, tedious, and uncertain method of treating both fracture of the patella and rupture of its ligamentous attachments may well be abandoned in favor of some form of operation calculated to secure an immediate union of the divided parts.

ADDITIONAL NOTES ON ABSORBENT COTTON AS AN ELECTRODE COVERING.

BY G. BETTON MASSEY, M.D.,

ELECTROTHERAPEUTIST TO THE PHILADELPHIA ORTHOPÆDIC HOSPITAL AND INFIRMARY FOR NERVOUS DISEASES.

SINCE the use of absorbent cotton for the above mentioned purpose was recommended by the writer, in a note published in THE NEWS, of February 7th last, quite a general adoption of the suggestion has occurred among electrotherapeutists. A further experience of nearly a year since the publication of the note convinces me that the suggestion, though relating to a minor detail, is one of no little practical importance, and should be invariably adopted for electrodes of all sizes when a covering is required.

It has been objected that absorbent cotton is inferior to sponge, in covering the two larger sized electrodes of Erb's scale, since it cannot be so well retained in place. For these large electrodes, a method different from the one that has been described should be used. A bundle of the cotton should be unrolled, laid flat on the table, and a piece of approprite size cut out with a pair of scissors, allowance being made for the necessity of covering the edges by lapping. This piece, and another on top of it to add to the elasticity, can be readily retained in place by a few turns of fine spool cotton wound over both back and face; or, more neatly, by stitching the edges across the back. Two or three layers make a more serviceable covering for these large electrodes than a single layer, and it need not be feared that additional layers will add much to the resistance of the circuit, as the experiments described below show that wet cotton deprived of its natural oil is a much better conductor of electricity than wet sponge.

Dr. Angell, of Rochester, New York, has suggested to me that cotton may be kept in place on the ordinary sized disks by means of small stationer's rubber bands to clasp it about the shank, permitting a ready renewal. I have, however, found the *original* method by twisting about the shank, as shown in the accompanying illustrations, to be both neater and more convenient. Fig. 1 illustrates the placing of a pinch on the face of a disk, and pressing the edges over. Fig. 2, the twisting motion that fixes the edges about the shank.

FIG. 1.

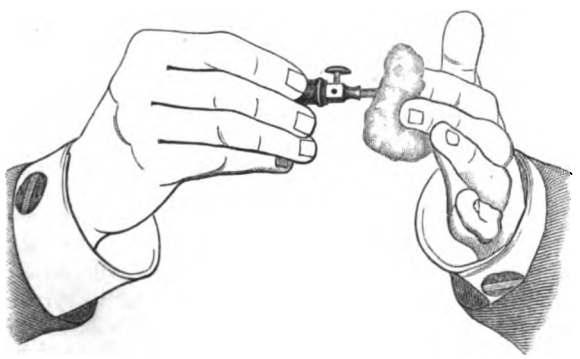

FIG. 2.

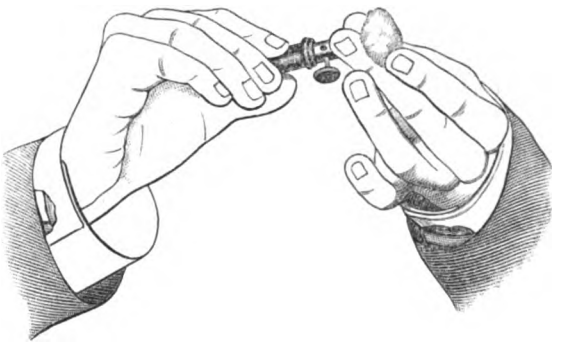

The resistance offered by pairs of sponge-covered and cotton-covered electrodes may be readily compared by anyone possessing a milliampèremeter simply, without the necessity of resorting to elaborate measurements. The accompanying table exhibits the results of such an experiment with two pairs of medium sized electrodes, covered respectively with sponge and cotton, and equally moistened with simple water. The circuit was completed by bringing the electrodes directly together:

Battery of 20 volts; circuit completed by:	Number of resultant milliampères in the circuit.		
	Electrodes lightly touched together.	Electrodes pressed together.	Electrodes heavily pressed together.
Electrodes covered with sponge	5	15	22
Electrodes covered with absorbent cotton . .	24	28	31

The results depicted show that 31 milliampères were obtained from 20 cells when the cotton poles were heavily pressed together, while but 22 were obtained from the same number of cells when the sponges were used. The table also shows the great variation in the current under ordinary accidental variations of apposition when the sponges were in circuit—from a minimum of 5, to a maximum of 22 milliampères: a variation quite undesirable in a number of delicate applications of this current for diagnostic purposes, and in the treatment of cranial affections.

1502 ARCH ST., PHILADELPHIA.

MEDICAL PROGRESS.

EPILEPSY AS A SEQUENCE OF DISEASED TEETH.—The literature of epilepsy contains some fifteen cases in which this disease was cured by the extraction of one or more teeth, but in none of these cases is it proven that the disease of the teeth was the direct

Digitized by Google

cause of the attacks. The following case, recorded by SCHWARTZKOPFF (*Deutsche Monatsschr. f. Zahnheilk.*, Sept. 1885, Heft 3), is apparently conclusive in this regard:

The patient, a man, aged twenty-seven, suffered severe pain in the right upper middle incisor, which was filled soon after. Thereupon appeared a swelling on the adjacent portion of the hard palate, which increased in size until it reached the soft palate, in which, soon after, a fistulous opening appeared. Every morning the patient expelled, by pressure with his finger, the purulent contents of the swelling, and was thereafter comparatively free from pain. The tooth, however, was loose, and somewhat painful when in use. Ten days after it was filled an epileptic attack occurred, which was repeated after several months. Gradually the attacks became more frequent, and in eighteen months after the first attack they occurred several times a week. The fistula remained during this entire period, and the patient used, under medical advice, bromides, atropia, and other remedies, without result. The tooth was then extracted, whereupon the fistula healed, and the epileptic attacks have not returned, although the extraction occurred four years ago.—*Centralb. f. Chirurgie*, Nov. 21, 1885.

TRASTOUR'S MIXTURE FOR BRONCHIAL CATARRH.—

Calcium iodide	1 part.
Lime-water	20 parts.
Distilled water	80 "

A soupspoonful before each of the two chief meals in a glass of diluted wine, or in milk. The use of the mixture must be continued for some time, and should be combined with laxatives, thoracic counter-irritation, and such other remedial agents as may be indicated.—*L'Union Médicale*, Nov. 19, 1885.

DISINFECTION OF APARTMENTS BY VOLATILIZED CORROSIVE SUBLIMATE.—DELBASTAILLE, in *The Annales de la Société Médico-chirurgicale de Liège*, highly recommends the method of disinfection employed by Koning, of Göttingen. This procedure consists simply in closing the doors and windows of the apartment, and then throwing about two ounces of bichloride of mercury upon a pan of live coals. The room is to be quitted immediately, and should remain filled with the vapors of the sublimate for three or four hours. It is then aired for several hours, the ordinary precaution being taken to prevent the entrance of the corrosive vapor into the respiratory passages. In order to prevent injury from such portion of the sublimate as may still cling to the room, the subsequent volatilization of sulphur in the apartment, in the ordinary manner, is desirable.—*L'Abeille Médicale*, Nov. 30, 1885.

CHRONIC CAFFEINISM.—In a paper recently read before the *Société Médicale de Reims*, GUELLIOT has analyzed the effects of the habitual excessive use of coffee, and pointed out certain resemblances and differences between the results of this and those of chronic alcoholic intoxication.

Passing over the familiar temporary erethism produced by coffee in those not accustomed to its use, we find that this beverage, taken in large and repeated doses, induces:

1. In men, sexual apathy, and even impotence.

2. In women, leucorrhœa. Little effect is exerted upon menstruation, and none upon either fecundity or the course of pregnancy.

The victim of caffeinism never presents the hebetude of ethylism; the face is pale and the eyes brilliant. Emaciation, or a tendency thereto, is marked, for there is no fat caffeinism. The various discomforts experienced in the morning by the typical alcoholic are here absent. The symmetrical anæsthesia of the extremities so characteristic of chronic alcoholism is rarely observed; on the contrary, the troubles of sensation take the form of hyperæsthesias and neuralgias.—*Revue de Thérapeutique*, Dec. 1, 1885.

PUPILLARY SYMPTOMS IN CHOLERA.—COSTE, of Marseilles, has made the following interesting observations in the course of an extended study of cholera during the recent epidemic in his city:

1. During the algid stage, even with cyanosis, if the pupils remain mobile, the stage in question will be successfully passed, and in the majority of such cases recover.

2. If, on the contrary, in the algid stage of cholera, the pupils remain contracted and motionless, or dilated and motionless, the patient invariably succumbs during the period of algidity.—*Archives Générales de Méd.*, Dec. 1885.

PTOMAINES OF CHOLERA.—At the session of the Académie de Médecine, on November 3d, was presented an account of the researches of MM. NICATI and RIETSCH, which may be thus summarized:

1. The injection into the veins of a healthy animal of an extremely minute quantity of a pure culture of the comma-bacillus will produce the characteristic choleraic symptoms, and ultimately death.

2. From such pure cultures may be extracted, by the method of Stas, a fluid ptomaine capable of producing the same effects.

3. From the liver and blood of cholera patients dying in the algid stage they have extracted a similar ptomaine, producing precisely the same effects on the lower animals.—*Archives Générales de Médecine*, Dec. 1885.

METHOD OF ADMINISTRATION OF HYPNONE.—VIGIER, to whom Dujardin-Beaumetz presented a large quantity of hypnone for experiment, makes the following report:

Hypnone is very sparingly soluble in water, and but slightly soluble in glycerine. Its solubility in alcohol permits the establishment of the following formula:

Hypnone	gtt. j.
Alcohol fortior	gtt. xvj.
Syrup of wild cherry . . .	gtt. xvj.
Syrup of orangeflowers . . .	f℥j.

Add the hypnone to the alcohol, then add the syrups, mix, and preserve in a stoppered bottle.

The amount of hypnone necessary to induce sleep varies from four to ten drops, taken at one dose. Fractional doses are not efficient.—*Gaz. Hebd. de Méd. et de Chirurgie*, Nov. 27, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, DECEMBER 26, 1885.

THE TREATMENT OF INTRACRANIAL HEMORRHAGE.

DR. C. B. WETHERLE, of St. Paul, Minnesota, reports in the *Northwestern Lancet* for November 15, 1885, a fatal case of injury to the head, in which he failed to secure the concurrence of the consultants in his wish to supplement one opening with the trephine by others, when the former proved insufficient for the removal of a clot and the arrest of hemorrhage.

The main points in the case were these: A man fell from a truck, and struck his head against the wheel. He rose and walked a short distance, and then became unconscious. His breathing soon became stertorous, with a "suggestion of Cheyne-Stokes respiration." His pupils were moderately dilated; and, on being moved, he had some slight convulsive twitchings. On examining the head, a small opening communicating with a fissure of one parietal bone was found. The pulse was 80, full, hard, and regular. In two hours the temperature was noted to be 104° in the mouth. The small wound was enlarged, and a single opening made with a trephine. About two drachms of coagulated blood were removed, and a trickling out of bright fluid blood followed. The pulse now increased in rapidity to 120 beats in the minute, and "the Cheyne-Stokes respiration became more marked." For fear of causing a fatal hemorrhage, the surgeons consulting with Dr. Wetherle refused to agree to another application of the trephine. The patient died twenty-two hours after the accident, and at the autopsy a clot about six inches long was found between the dura mater and the cranium, and one the size of an almond on the surface of the pia mater. The former was due to hemorrhage from a branch of the middle meningeal artery. As might be expected, the reporter refers to the recent paper of Dr. John B. Roberts, advocating more active interference in cases of injury of the head, and regrets that his judgment was overruled by his colleagues.

We call attention to this case because the study of the surgery of the skull is now at what will probably prove to be an important epoch in its history. In regard to the phase of it suggested by the experience of Dr. Wetherle we can hardly do better than to refer our readers to the admirable and comprehensive paper of Wiesmann, of Zurich: "Ueber die modernen Indicationen zur Trepanation mit besonderer Berücksschtigung der Blutungen aus der Arteria meningea media," published in the *Deutsche Zeitschrift f. Chirurgie*, Bd. xxi., xxii., 1885. It will be observed from the title of this paper that it deals especially with the matter of bleeding from wounds of the meningeal artery. This is studied exhaustively from a mass of statistics bearing upon its causes, symptoms, diagnosis, prognosis, and treatment. In regard to some of the points dwelt upon by Wiesmann we think it worth while to say a few words. In the first place, as to the causes of bleeding from the meningeal arteries. To the common traumatisms, in which there is an obvious lesion of the skull, must be added those injuries which, as we have recently seen in speaking of fractures by so-called counterstroke, alter the shape of the skull without breaking it. The possibility of the rupture of bloodvessels within the skull in this way has been denied, and that most recently by Marchant in 1881. But it was recognized long ago, allusion to it being made in some of the oldest writings; and new cases in which it has occurred will be likely to be discovered, when the possibility of its occurrence is recognized and search is made for it.

Passing by a number of interesting points discussed by Wiesmann, we desire to call attention to some in regard to the diagnosis of bleeding from the middle meningeal artery. Of course when this is associated with a fracture, in the course of the artery, and accompanied by the symptoms of pressure, the diagnosis is easy enough. But the fact must not be overlooked that the signs which confirm the suspicion of the formation of a clot, in the case just mentioned, may suffice to indicate its formation almost as clearly when there is no opening in the skull at all. The most important of these signs are those of which we have recently spoken, in discussing compression of the brain in THE MEDICAL NEWS, November 14, 1885. Thus we have the evidences first of irritation, and then of paralysis of the centres of the vagus and vasomotor nerves in the brain. The pulse under the influence of a comparatively rapid increase of intracranial pressure becomes slow, hard, and tense. The respiration becomes slow, labored, and stertorous; and—a point

Digitized by Google

to which we have not yet adverted—the temperature sometimes undergoes a notable rise, due to irritation of the heat centre. In this connection we would refer to an interesting paper by Dr. W. Hale White, on "The Theory of a Heat Centre from a Clinical Point of View," which appears in *Guy's Hospital Reports* for 1884.

One of the most important points in the diagnosis of hemorrhage within the skull is the brief period of freedom from manifestations which indicate severe injury of the brain. As in the case of Dr. Wetherle, it is often recorded that a patient, after a fall or a blow, has stood erect, or walked a certain distance, and seemed, indeed, to have received no great hurt. In such cases the symptoms of danger come on a little later, and this very delay points almost infallibly to an intracranial hemorrhage. In Dr. Wetherle's case, it will be observed, not one of the elements of diagnosis which we have mentioned was wanting.

In regard to the treatment of injuries of this sort, it is interesting to note that Wiesmann found that, out of 147 cases treated expectantly, 131 died; that is, about nine-tenths. Of 110 cases treated actively, only 36 died, or about one-third. Further, he shows that in the majority of the cases which ended in death the extravasation was not reached, and of course it was not removed. These figures certainly appear to justify his conclusion that operative interference, either by removal of fragments or resection of the skull, is to be carried out whenever there is a certainty, or a very strong suspicion, that there has been a rupture of, and hemorrhage from, the middle meningeal artery. He does not hesitate to recommend an operation even when a blow has been inflicted upon one side of the head and the symptoms point to a rupture of the artery on the other. The operative procedure which he advises includes removal of any clot which has formed, controlling the hemorrhage, washing out the cavity, introducing a suitable drainage tube, and closing the wound with perfect antisepsis. The best way to control the hemorrhage is by means of a ligature, or by acupressure, or by an aseptic tampon of iodoform gauze.

We do not wish, any more than does Wiesmann, to occupy the position of one who would advise going in search of a suspected bleeding point with the trephine; but in view of the cases he has adduced, and of those cited in the remarkable paper of Quesnay, published more than a hundred years ago, on "Multiplicité de trépans," in the *Mém. de l'Académie royale de Chirurgie*, tome i., we cannot hesitate to recommend the question as to the propriety of bolder interference in cases of known or suspected hemorrhage from the middle meningeal artery to the renewed consideration of surgeons.

THE BACILLUS OF SYPHILIS.

ALTHOUGH scarcely a year has passed since the announcement, by Lustgarten, of Vienna, of a microorganism in connection with syphilitic products, there are already numerous communications on the subject, and the claim of this bacillus to be admitted into the ranks of the specific microbes has been vigorously contested. Lustgarten attempted to show the presence in syphilitic processes at all stages of a bacillus, which presented certain peculiarities in form and color relations, but of which, however, cultures could not be obtained.

The observations of DOUTRELEPONT and SCHÜTZ in Germany, and of BABIES, GIACOMI, and LELOIR in France, confirm the statement of Lustgarten. ALVAREZ and TAVET, pupils of Cornil, state in the October number of the *Archives de Physiologie*, that they have failed to find the bacilli in sections of syphilitic growths, but have been able to demonstrate them in the secretions of chancre, mucous patches and ulcers, occasionally in other pathological secretions, as soft chancres, and herpes preputialis, and in the normal secretions of the genital organs, the smegma of the glans penis, and in the secretion of the labial folds. Morphologically, as well as in color relations, the bacilli of these three categories, syphilitic, non-syphilitic, and normal genital secretions, are identical. KLEMPERER, of Leyden's clinic, has published in the *Deutsche med. Wochenschrift*, No. 47, conclusions similar to the French observers, confirming their statements of the identity of the smegma bacillus with the form described by Lustgarten. In the same journal, No. 48, MATTERSTOCK, on the other hand, while admitting the similarity of the smegma bacilli with some of those in syphilitic secretions, holds that there are other forms differing in color reactions, which further investigations may show to be specific. Altogether, these observations seem to dispose for the present of Lustgarten's bacillus.

But with the annihilation of one microbe another is brought forward to take its place. In No 48 of the *Deutsche med. Wochenschrift* is a preliminary communication on this subject by DISSE and TAGUCHI, of the Medical Institution of Tokio, Japan, which, on paper, rivals as a comprehensive demonstration Koch's famous essays on tubercle. They claim to have discovered in the blood and lesions of syphilitic patients a bacillus with spores, which they have been able to cultivate in series and inoculate successfully in dogs, sheep, rabbits, and mice, with the production of a local lesion with induration and subsequent systemic infection. From the blood and tissues of the animal thus experimented upon, cultures could be obtained, and further inoculations were successful. The bacilli were demonstrated in the embryos of a pregnant rabbit two months after infection, and

Digitized by Google

in severe cases gummata were found in the placenta and liver, and in other syphilitic bone lesions. The possibility of the process being tuberculous was excluded.

LANOLIN: A NEW BASIS FOR OINTMENTS.

IN the *Berliner klin. Wochenschrift*, No. 47, 1885, Liebreich describes, under the term "Lanolin," a new basis for salves, for which are claimed certain advantages over the glycerine fats and mineral oils, such as vaseline. In the various keratin tissues—skin, hair, hoof, and feathers—the fatty acids are united with cholesterin, forming a peculiar fat, to which the name lanolin is given, as it can be most readily prepared from wool. One of its most remarkable properties is the power of taking up an equal bulk of water, but the difficulty with which it decomposes, and the rapidity with which it is absorbed, are the qualities which make it especially valuable in comparison with the neutral glycerine fats and vaseline. The readiness with which lanolin is absorbed by the skin is explained by the fact that it is the natural fat of epidermic tissues. Rubbing the hands with a 5 per cent. carbolic acid ointment made with it produces a sensation of numbness, without any irritation, in from one to two minutes, and a sublimate salve, 1:1000, will give the characteristic metallic taste a few minutes after inunction. The addition of 5 or 10 per cent. of fat or glycerine to lanolin is recommended as giving a better consistence to the ointment.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, November 24, 1885.

THE PRESIDENT, CHARLES MCBURNEY, M.D., IN THE CHAIR.

DR. R. J. HALL presented the following report:

THE BACILLUS OF SYPHILIS.

In May, 1885, Dr. Lustgarten published his pamphlet stating that by a new method, devised by him, of staining and bleaching syphilitic tissue, he had found in sections of the specimens examined, sixteen in all, a distinct bacillus; these bacilli were found in small numbers. In August, 1885, in the *Fortschritte der Medicin*, Bd. 4, No. 16, there was published an article describing Giacomi's method of staining the same bacillus.

Both methods have been used by Mr. Freeman, under the guidance and with the supervision of Dr. R. J. Hall. The Lustgarten method, though more troublesome, was the more satisfactory. The statistics given below were obtained from specimens stained by the Lustgarten method. 7 specimens of syphilitic tissue were examined; 5 primary, all typical hard chancres; 2 secondary syphilitic papules.

Specimen No. 1: No history; sections received already cut; typical hard chancre from prepuce. Section No. 1: Found 1 bacillus in a cell; found 2 bacilli in a cell; found 3 bacilli in a cell.

Specimen No. 2: No history; typical hard chancre from prepuce. Section No. 1: Found 1 bacillus in a cell; found 1 bacillus in a cell; found 3 bacilli in a cell. Section No. 2: found 2 bacilli in a cell; found 18 bacilli in a cell. "A flat cell in a condition of granular degeneration, no nuclei being visible. Counted in it 18 bacilli exactly corresponding to Lustgarten's description, and one or two dots which might be portions of bacilli partially concealed through lying obliquely." Section 3: negative.

Specimen No. 3: Typical hard chancre; August 11, 1885; William Muller, age sixteen. Six weeks ago sore appeared at peno-scrotal junction with a simple balanitis; connection one or two weeks previous; three weeks ago inguinal glands enlarged, and eruption on legs. Examination: *Typical hard chancre;* primary roseola on abdomen; syphilitic buboes; chancre excised. Microscopic examination: Section No. 1: Negative. Section No. 2: Found 2 bacilli in a cell; found 1 bacillus in a cell. Section No. 3: Negative.

Specimen No. 4: Syphilitic papule; August 11, 1885; Rudolph Bogli, aged nineteen. Five months ago extensive chancroid with phimosis, was circumcised; now lymphatics swollen; 2 characteristic syphilitic ulcers on right forearm; several indurated papules on scrotum; *large indurated papule*, ¾ inch in diameter, greatly resembling a primary chancre, on line of circumcision; no other secondary symptoms; induration on penis excised. Microscopic examination: Section No. 1: 2 bacilli in a cell. Section No. 2: None. Section No. 3: None.

Specimen No. 5: Typical hard chancre; Richard Kane, aged thirty-six; *typical hard chancre;* first noticed sore eight days ago; had connection four weeks previously; no eruption; chancre excised. Microscopic examination: Section No. 1: Found none. Section 2: Found 1 bacillus in a cell; found 2 bacilli in a cell; found 1 bacillus in a cell; found 1 bacillus in a cell. Section 3: found 1 bacillus in a cell.

Specimen No. 6: Syphilitic papule; Herbert Smith, aged twenty-nine; gonorrhœa eighteen months ago; last connection two months ago; two weeks ago noticed *indurated sore on prepuce* and enlarged glands in groin; a few days ago roseola; all these symptoms present; induration excised. Microscopical examination: Section No. 1; found 1 bacillus in a cell; found 1 bacillus in a cell; found 1 bacillus in a cell. Section No. 2: found none. Section No. 3: found none. Section No. 3: found 1 bacillus in a cell.

Specimen No. 7: Syphilitic hard chancre; September 21, 1885; Joseph Grassley, aged nineteen; ten days ago connection; four days ago *sore on prepuce;* size, split pea; hard base covered with yellowish material; excised. Microscopical examination: Section No. 1: found 3 bacilli in a cell; found 2 bacilli in a cell. Section No. 2: found none. Section No. 3: found 1 bacillus in a cell; found 1 bacillus in a cell.

Stated Meeting, December 8, 1885.

DR. H. B. SANDS read a paper on

RUPTURE OF THE LIGAMENTUM PATELLÆ, AND ITS TREATMENT BY OPERATION.

(See page 701.)

DR. R. F. WEIR exhibited the patient treated in St. Luke's Hospital for rupture of the ligamentum patellæ, who was referred to in Dr. Sands's paper. The accident occurred in 1869. The patient, a man, æt. 47, while crossing the street, slipped and fell, but did not strike the knee. The rupture resulted apparently from his attempts to save himself from falling. He was taken immediately to the hospital. The patient was recently looked up, and when asked, in the absence of a written history, upon which side the accident occurred, said the left, but he had since thought over the matter a good deal and was unable to say positively whether the right or the left leg was affected. The result is a remarkably good one, both as to function and physical appearances. The patient can use the one limb as well as the other. Dr. Weir was unable to detect any difference in the appearance or length of the two patellar ligaments. The man was treated in the hospital about a month by a plaster-of-Paris splint. He then went home, and by incautious walking got up a synovitis, and was confined to his house for another month.

Dr. Weir said four cases of rupture of the ligamentum patellæ had come under his notice, the first being during his interne service in the New York Hospital, and was probably the one reported by Dr. Sands as occurring in that hospital under the care of Dr. Markoe. The second was the one presented to-night. The third occurred in a gentleman from the West, treated at the Sturtevant House. The result is uncertain as to function, as he was treated only three or four weeks, when he went to his home, but union had satisfactorily taken place.

The fourth case, which, however, did not properly belong to the class referred to by Dr. Sands, occurred in a case of stiffness of the knee-joint supposed to be due to fibrous anchylosis of the patella, and in which an attempt was made to practise *brisement forcé* with the result, not of fracturing the patella, but of rupturing the ligamentum patellæ. It healed promptly.

Dr. Weir further reported that within the past two weeks he had been consulted by Dr. Loring, of Valparaiso, Indiana, about a case of a woman sixty-five years of age, who fell and sustained a rupture of the ligamentum patellæ on the left side, from muscular violence. The gap was now the breadth of a hand, and the limb was incapacitated except with the use of a posterior splint which enabled her to get about by the aid of crutches. The case was additionally interesting as having occurred in a female.

Dr. Weir thought it is not generally enough recognized that the ligamentous band uniting the fragments of a fractured patella is frequently stronger than the bone itself.

Dr. Weir remarked that it had been suggested, as a means to overcome the distance between the fragments of a fractured patella, to fracture the thigh bone. May this not be resorted to as a last measure in certain instances, where an operation is required, when the scoring of the quadriceps muscle will not permit the approximation of bony fragments in fracture of the patella, or of the tendon ends in rupture of the ligamentum patellæ?

Dr. L. A. STIMSON said that the creation of a gap in cases of rupture of a tendon at its lower end is not produced solely by contraction of the muscle, as of the quadriceps femoris, but is produced in part, as in Dr. Sands's case by retraction of the ligament itself. This has been observed constantly after fracture of the patella, and it is one of the reasons why it is so difficult to obtain union without a gap after that accident. Fracture of the thigh will not overcome a gap due to that cause.

THE PRESIDENT suggested the substitution for fracture of the thigh bone in certain cases for overcoming the gap, division of the patella, trusting to the well-known facility of formation of a ligamentous band to unite the divided patella. This procedure may be resorted to in some cases in which the separation is great and cannot be overcome by partial division of the muscle.

POTT'S FRACTURE AT THE ANKLE.

DR. L. A. STIMSON presented a specimen illustrating a common fracture, but one in which we seldom have an opportunity to obtain the injured parts for study. The patient was sixty years of age, and sustained Pott's fracture at the ankle from a fall apparently caused by a cerebral lesion. He died three days after admission to the hospital. The characteristic deformity of the fracture was present, and crepitus was much more marked than usual. At the autopsy the fracture was found to be very oblique, beginning in front an inch and a half above the tip of the malleolus and extending upward and backward more than two inches. The internal lateral and lower tibio-fibular ligaments were ruptured, and the outer malleolus was displaced from a half to three-quarters of an inch outward from the tibia. There was no fracture of any other part.

THE AMERICAN PUBLIC HEALTH ASSOCIATION.

Thirteenth Annual Meeting, held at Washington, D. C., December 8, 9, 10, and 11, 1885.

(Specially reported for THE MEDICAL NEWS.)

WEDNESDAY, DECEMBER 9TH.—SECOND DAY.
MORNING SESSION.

DR. P. H. BRYCE, Secretary of the Provincial Board of Health, Toronto, Canada, then read a paper on

SMALLPOX IN CANADA, AND THE METHODS OF DEALING WITH IT IN THE PROVINCES.

He stated that he felt like a lawyer before a criminal court, pleading for a client who had boldly declared himself "not guilty" of an epidemic of smallpox. He then proceeded to relate the particulars of the outbreak of the present year, and stated that it was not until a prominent politician had died of the disease that the entire outside world awoke to the situation. The number of deaths was about 3100. Unfortunately, the epidemic was not confined to Montreal alone. Among the French the system of sanitation was unable to grapple with the disease. Knowing this, the health authorities of Mon-

Digitized by Google

treal provided the local boards of health with instructions, and did everything in their power to ward off the danger. He entered into a full description of the means taken to prevent the spread of the disease. All goods, and all people passing in and out were strictly examined, the railway companies assisting in the work of inspection. Every car was examined, and all the railway officials were vaccinated. A list of streets and numbers in Montreal were furnished, and passengers were questioned as to their residence, and if it was found that they lived in an infected neighborhood, they were detained for a time, and their baggage fumigated. Similar precautions were taken in the Province of Quebec. He thought it very creditable to Ontario that no case of disease, so far as known, had passed through their internal quarantine to the neighboring States, and he thought the quarantine at Suspension Bridge should be removed.

DR. HINGSTON, president of the Central Board of the Province of Quebec, said that he could not help thinking that Dr. Bryce's paper was very strong from an Ontarian point of view. Montreal has been afflicted as perhaps no other city on this side of the Atlantic. But, on the other hand, he wished to say that never did city make such tremendous efforts to get rid of an epidemic as did Montreal. Smallpox did not originate in Montreal. It did not drop as the dew from heaven upon the earth beneath, it came to us from outside our province. I shall not say whence it came. It was traced from one place to another, then to some State in the Union which has no State Board of Health. Let us leave it there. If there are any states in the Union which have not State Boards of Health, it will be a good excuse for their creation. There is no denying that when it did come, however, a section of the city, the most thickly settled quarter, was unprepared to receive it; that is to say, it was prepared to receive it well and to house it. The soil was well prepared to receive it. In Montreal for several years past, pamphlet after pamphlet has been printed and distributed, disseminating anti-vaccination views. Unfortunately, too, the beautiful French language has been the medium of conveying these views.

Now, it must not be imagined that the population of Canada is not a vaccinated population, but in consequence of the dissemination of these views in regard to the uselessness of vaccination, the population of Lower Canada, at least of Montreal, is not a vaccinated population. The writing against vaccination began twelve or fifteen years ago in the French language, and great mischief has been done. Notwithstanding the severity of the epidemic to which we have been exposed, these views are still being disseminated, but the public press has been ashamed to yield its columns to that purpose. So, after the epidemic began, we had to begin by educating that section of the people. What added to the difficulty was this: A certain portion of the population had to be approached in a different way from other sections. A prejudice existed against civic vaccination. When the erysipelas developed after vaccination, or something of the kind happened, the anti-vaccinationists would ascribe it to the use of impure vaccine virus, and thus a certain class of people would become more and more opposed to being vaccinated. That, however, has happily altogether disappeared, and we are indebted in a large measure to the commercial people of our city for this. They made it a rule that no one should be employed in factory, store, or warehouse without a certificate of vaccination, and also a certificate showing freedom from infection in their homes and houses. This regulation was adopted by both the Ontario and American authorities; persons who were imbued with anti-vaccination views found when they crossed the frontiers to the United States, they were met by a gentleman who politely but firmly told them, "You cannot enter our territory until you show marks of recent vaccination." In that way our hands were strengthened. Indeed, we have accomplished more in a few months than otherwise we could have accomplished in as many years.

Ontario was comparatively free from infection and they were as anxious to preserve their province as the people of the United States were to protect theirs. The City of Montreal accomplished more, I think, in regard to vaccination than has been accomplished by any city of the same size in the same period of time; and this was accomplished by writing and disseminating pamphlets, by using the public press, and by organizing vaccination bureaus.

Montreal is peculiarly situated. It is a city of 180,000 inhabitants. But it has a large outlying population which would not come into line. The Government of Quebec, finding that the City of Montreal could not deal with this outlying population, made it into a distinct municipality, with a board of health to which arbitrary powers were given. Montreal is situated 180 miles from the seat of Government, and it had to create legislation. But the rules and regulations were sent by special messengers, and within forty-eight hours the regulations became law. If there was any want of diligence, it was not with the Government, but with the authorities. Vaccination has been accomplished on a very large scale. Isolation was found difficult.

What was the position of Montreal on the 28th of February last? There was not a place prepared for isolation. The city had been free from smallpox for several years: it had not taken precautions to have a building ready. Its population was not vaccinated. Thanks to the ideas which prevailed, thanks also to the opposition created in the minds of many, by writers in the French language, at the beginning of that epidemic, there was no building into which a person suffering from smallpox could be placed. A little censure has been passed upon us for this reason; and it was said that the patient who first came to Montreal was admitted to the general hospital. The statement is true and untrue. He was admitted to the largest building in the city, but with a wing more completely isolated than any other building in Montreal; and it is yet to be shown that a single case occurred in his vicinity. It was found to be almost impossible to get persons to leave their houses when afflicted with the smallpox. In some cases it was necessary for the Mayor, followed by the police, to go and by force remove them. Indeed, in the minds of some lawyers and some judges of our courts, it was conceded that the law had been exceeded by the authorities; but the people were prepared to go beyond the law, or even break the law, to carry out sanitary regulations.

First of all, a building was procured, but was soon crowded. Influential persons had to go from house to house and coax and threaten, and induce cases to enter

Digitized by Google

it. What did Montreal do? It took the largest, the handsomest, the best situated building in the town, that for many years has served the purpose of an exhibition building, and there complete isolation was obtained.

Then, again, objection was made to the placards. Sometimes persons were maltreated who were engaged in putting up these placards, and at first no sooner were the placards put up than somebody tore them down. But by perseverance we finally succeeded, and now when a placard goes up it stays until it is taken down by the authorities. The same way with disinfection. But we finally succeeded in this also, and it has been carried on in accordance with the most recent views on sanitary science.

Another difficulty was that smallpox existed amongst a large section of the poorer population, and they had to be supported. A thoughtless man, and one who looks only from the sanitary point of view, is apt to put a placard on the door, and leave the place. Yet if this is done, the baker and other tradesmen will be afraid to go to that house, for fear their customers will think them contaminated. So we had to go to work and support these families, and hundreds and thousands were supported by the city. It was done cheerfully, not only by the employés, but by a large number of citizens, able and intelligent citizens, who coöperated with the city.

The provincial board of health had also its work. It had, first of all, to formulate rules and regulations concerning every question. After they were completed, it was found by a lawyer that certain links were wanting, and they had to be supplied in the French and English languages. Rules had to be laid down for isolation and vaccination. The rules for vaccination cost him seven or eight nights of intense work. They had to enlist the clergy and physicians in the cause. In that way they got, in a short time, boards of health over almost the entire Province of Quebec.

We were assisted by the railroads. They coöperated with the provincial board, and sometimes at great sacrifices. When we pointed out that at such a place on the railroad line there was disease, and we could get no assistance whatever, the order went forth to pass that place. In that way we accomplished much. Generally before twenty-four hours the municipality was upon its knees, coming to us and asking for relief. Without the railroads we never could have done what we did. They may have exceeded their authority a little in doing this, but it was no time to strain at a gnat. They are public carriers, and by their charter they are obliged to stop at certain places, and an action for damages might arise if they failed to do so, but these railroads are prepared, and I hope every railroad will be prepared, to act in the same manner.

Assistance was obtained from the Minister of Education. Instructions were sent to the schools and colleges to receive no pupils without a certificate of freedom from infection in their houses, and freedom from disease in their persons. The schools and colleges and seminaries of learning coöperated with the board very cheerfully. There were but two institutions that would not yield, but they were very glad to yield before many days passed, because we held them up, or threatened to hold them up, to public scorn and contempt.

The provisional government of the province of Quebec also coöperated with the board.

Shortly after the Board was formed, a law was passed requiring compulsory vaccination, and boards of health were instructed to vaccinate. But, compulsory vaccination, to be successful, must depend on a law of public registration of births. We have no law for the compulsory registration of births as in European countries. In Germany they have a law of compulsory vaccination, but they have also a law of compulsory registration of births. When a child is born, its birth is registered and a certificate of birth is procured. What we propose doing at the next session of the legislature is to obtain a law of compulsory registration of births, and compulsory vaccination will follow as a matter of course. As it is now, there is no machinery by which it can be done. You go to a man's door and you ask if there is a child under a certain age. He may say yes or no, or he may tell you to go about your business. But with compulsory registration, an officer can sit in his office and make out a list of so many people of such a street and number and name not yet vaccinated. After notification they must have a certificate of exemption within five or ten days, or else we will step in and know the reason why.

Dr. Hingston then alluded to the death-rate of Montreal. It has been stated by Dr. Bryce to be about 3000 persons in a population of 180,000. That is an enormous mortality. The death-rate, however, according to months, may be of interest. The death-rate in April was 6, in May 10, in June 13, in July 40, in August 239, in September 660, in October 1391, still on the increasing scale. It suddenly dropped then to one-half. It dropped from 1391 to 633, and from 633 again to 300.

Now this is an enormous death-rate. The death-rate is large, but he was happy to say the birth-rate is simply enormous. No country in the world, no country anywhere, can give such a birth-rate as the Province of Canada.

DR. STEUART called attention to one thing that had not been touched upon. That is the danger that occurs from public funerals. If the health officer and the authorities of every city where smallpox occurs would prevent public burials of smallpox patients, the danger would be very much lessened. In an epidemic that occurred in Baltimore two or three years ago, the great start the disease obtained was from a public funeral, which took place in a church. Five or six hundred people were present, and in that locality within two or three weeks the disease was dotted around in four or five houses, and hundreds of cases came from that one case. The authorities should take possession of a house and watch every case as soon as it is reported, and have reports made daily to the health authorities, and, when death occurs, destroy everything that has been in contact with the patient, and disinfect the house properly, and more especially the body.

DR. C. W. CHANCELLOR, Secretary of the Maryland State Board of Health, then read a paper entitled

IMPURE AIR AND UNHEALTHY OCCUPATIONS AS PREDISPOSING CAUSES OF PULMONARY CONSUMPTION.

He said that in England one-fifth of all the deaths are from pulmonary consumption; in France one-sixth, and in Germany and Austria about one-seventh. In the United States, according to the Census of 1880, one-eighth of the deaths were from consumption. Pure air

Digitized by Google

is as essential to health as pure food and drink. When contaminated from any cause, it acts as a slow poison, and gradually undermines the constitution. Too little attention is paid to the proper ventilation of living apartments. The sallow complexions of persons living in apartments not properly ventilated plainly indicate the injurious effects produced by the poisonous air they breathe, and although its pernicious effects may not be sensibly felt, it gradually preys upon their constitutions, and is often the cause of incurable consumption, which is frequently imputed to other causes. It is true that some occupations are more unhealthy than others. Inhabitants of cities are undoubtedly less hardy and more subject to pulmonary diseases than those of the country. City people are generally pale, and their muscular system is poorly developed. Want of a free circulation of pure, uncontaminated air is the most powerful cause of this. In addition, in cities there is more to excite the passions. Overindulgence in eating and drinking is more common, while many of the occupations are sedentary and more unhealthy than those in the country. Salesmen are liable to disease because they are constantly in a superheated and more or less impure atmosphere, and often exposed to sudden changes of temperature. Artisans and laborers are often compelled to work in rooms badly located, badly ventilated, and abounding in unhealthy dust. Under such circumstances the most substantial nourishment, the most temperate habits, cannot prevent them from becoming blanched and weakened by disease. A number of statistics showing the relative length of life of different workers was then given. He said the problem was, how to environ each worker in a pure atmosphere. The solution of the problem could be easily suggested by the sanitary engineer, but its execution was a matter for the several State Legislatures to control. He thought it very desirable that consumption hospitals should be established in every city.

EVENING SESSION.

DR. E. M. HARTWELL, of Johns Hopkins University, read a paper upon the

GERMAN SYSTEM OF PHYSICAL EDUCATION,

in which he described the origin of gymnastics in Germany, beginning in the year 1700. In the city of Berlin every child at school is taught the physical exercises two hours in each week. Every one in Germany has to undergo such training. The men are so trained for the army; and upon entering it they have to undergo a further severe course of training, the results of which are apparent in the physical endurance and courage of the soldiers. A German soldier, with his musket and accoutrements, can scale a twenty-foot brick wall, or jump an iron-spiked fence, without danger of catching his clothing in the spikes. In the German schools gymnastics are compulsory, and of the pupils less than 10 per cent. are exempt, and then only upon the certificate of a physician. There are in Berlin ninety-eight gymnasiums; and in 1880 and 1881, of the $1,760,000 appropriated by the city for educational purposes, one-thirtieth of that amount was expended for gymnastics. In 1885 there was appropriated, for the Royal Normal School of Gymnastics, something over $21,000, and teachers from all parts of the empire go there to learn, so that they may go back to teach their pupils. Officers of the army become pupils, so that they may teach the soldiers. The speaker thought we could not do better than to introduce the system in this country; of course, adapting it to our institutions, thus enabling our youth to bear the strain of study.

DR. O. W. WIGHT, Health Officer, of Detroit, Mich., then read a paper on

EXPERIENCES IN DISINFECTING SEWERS.

He described the bad condition of the sewerage of Detroit, the lack of system in its construction, stating that very frequently large sewers are so connected as to empty into smaller ones, and that outlets are often higher than inlets. He gave a humorous account of the difficulties encountered in his crusade against sewer gas, and the ridicule and opposition which greeted him when he proposed to disinfect the sewers. He stated that some time previous to his efforts in that direction, two medical men of the city had descended into one of the sewer manholes, and remained there, to use their own words, "twenty-five consecutive minutes," and upon ascending they reported that the air of the sewer was "chemically pure!" In spite of opposition, however, he entered upon the work of disinfection. First, he used 75,000 pounds of copperas, and the citizens joined him and used 200,000 pounds more, in the 200 miles of sewers in Detroit. He then purchased three tons of brimstone, and burnt it in iron pails let down into the manholes by chains. He found that the sulphurous acid gas travelled through the sewers faster than he could travel on the surface in his buggy. The penetrating odor of the gas discovered innumerable defects in house plumbing, and he related some very ludicrous scenes in that connection. It was found that the disinfection caused a marked diminution in the number of cases of diphtheria and scarlet fever—or almost a total cessation of those diseases. The whole cost was less than $1300.

The last paper read was that of DR. BENJAMIN LEE, of Philadelphia, entitled

THE DEBIT AND CREDIT ACCOUNTS OF THE PLYMOUTH EPIDEMIC.

His theory was that the epidemic originated from Philadelphia. He stated that there were 1153 cases, which cost $59,100.17; hospital cases, $8000; loss of earnings to patients and others, $30,020.08; capital represented by loss of income of 114 persons who died, $613,984; Total, $711,104 25.

RHODE ISLAND MEDICAL SOCIETY.

Semiannual Meeting, held at Providence, December 17, 1885.

(Specially reported for THE MEDICAL NEWS.)

THE PRESIDENT, OLIVER C. WIGGIN, M.D., IN THE CHAIR.

THE Committe appointed at the last quarterly meeting to consider a communication from the American Medical Association upon

STATE REGULATION OF THE PRACTICE OF MEDICINE,

reported as follows: "It is our opinion that an Act to regulate the practice of medicine would prove of very

Digitized by Google

great value to our citizens, and, if presented in a proper form, would be readily adopted by the Legislature. But we do not believe that the proposed Act referred to is well adapted for the purpose, as it is not only lengthy and cumbersome, but would establish a new branch of the State Government, and on this account alone would be sure to meet with strong opposition. We suggest that a better plan would be to place the licensing power in the hands of the State Board of Health, making such changes in the constitution of the Board as will be necessary."

The report was adopted.

The Chair then announced the following appointments:

DELEGATES TO MEDICAL SOCIETIES.

Maine.—Drs. A. D. Weeks and W. H. Traver.

New Hampshire.—Drs. W. F. Hutchinson and G. W. Jenckes.

Vermont.—Drs. E. M. Snow and W. R. White.

Massachusetts.—Drs. E. T. Caswell and W. F. Morrison.

Connecticut.—Drs. A. G. Browning and W. H. Palmer.

New York Medical Society.—Drs. C. O'Leary and A. Potter.

New York Medical Association.—Drs. S. W. Francis and J. H. Morgan.

New Jersey.—Drs. F. B. Fuller and C. H. Fisher.

BOARD OF MEDICAL EXAMINERS:

Drs. G. W. Carr, term to expire in 1886; F. B. Fuller, term to expire in 1887; J. W. Mitchell, term to expire in 1888; R. F. Noyes, term to expire in 1889; Charles O'Leary, term to expire in 1890.

The Board of Censors also nominated Dr. William R. White for

ANNIVERSARY CHAIRMAN

at the next annual meeting, and the nomination was approved by the Chair.

DR. GEO. F. KEENE read a paper upon

A NEW METHOD OF TREATING COLLES'S FRACTURE,

and showed a new splint of his own devising, made of a piece of telegraph wire bent first into the shape of a hairpin and then bent upon itself some three and a half inches from the curved extremity, nearly at right angles. The larger and free ends of the wire were united by two pieces of tin, looped over each, the tin being slightly curved so as to fit the shape of the arm. This splint, suitably padded, is to be applied to the palmar surface of the forearm, with the palm of the hand resting against the bent loop of wire, in a position of *extension* on the forearm, rather than flexion, as is the case when the ordinary splints are used. Dr. Keene had used his splint in three cases with most satisfactory results.

DR. CASWELL said Dr. Keene's idea was contrary to all previous positions recommended in the treatment of this injury, and that he should like to give it a trial. His own impression was, however, that if the fracture be properly reduced at the outset, it makes little difference what apparatus is employed subsequently, provided passive motion is employed early enough.

DR. W. F. MORRISON reported

A CASE OF PYELONEPHRITIS,

and showed a specimen which was a right kidney weighing fourteen ounces, and containing five pouches which had been found to be filled by about four ounces of pus, altogether. These sacs or pouches were about the size of English walnuts. In three of them were imbedded brownish calculi, respectively 2, 1¾, and 1½ inches in length, about ½ inch in diameter and of irregular shape. The patient was a woman forty-four years old and a correct diagnosis was made some weeks before her death.

A paper on *Nasal Catarrh; Its Immediate and Remote Effects*, by Dr. F. P. Capron, was read by its title and referred to the Publication Committee.

THE PRESIDENT read a paper on

CLINICAL OBSERVATIONS ON THERMIC FEVER.

The clinical history of three cases of sunstroke was given in detail. All were successfully treated. In one case cerebral meningitis developed, which the writer thought would probably have been prevented if venesection to the extent of two or three pints had been performed at the onset. In another case the patient, a woman, was, when first seen by the writer, in a condition so critical that death seemed imminent. She was made to inhale about a drachm of chloroform, which fortunately was available at the instant, and which apparently was the means of warding off death.

The method of treatment in these cases embraces the free application of cold water, or of hot water, according to the bodily temperature and the condition of the cutaneous circulation; the administration by the mouth or rectum, of a decoction of table tea (2 ozs. of Formosa to a pint of water), giving ℥ij every two hours; the elixir of the valerianate of ammonia; the bromides; the lancet or leeches to relieve cerebral engorgement.

THE CHAIR announced the

DEATH OF DR. JOHN W. SAWYER,

Superintendent of the Butler Hospital for the Insane, and one of the Vice-Presidents of this Society, which occurred on the 14th inst.

The following preamble and resolutions were adopted by a rising vote:

Whereas, An inscrutable Providence, who wounds only that through His own mysterious reasons He may really benefit, has taken from the Rhode Island Medical Society its beloved Vice-President, Dr. John Woodbury Sawyer; therefore

Resolved, That in Dr. Sawyer not only had the Butler Hospital a medical superintendent whose first and only thought was the welfare of the unfortunates whom it was his duty to protect, to care for, and to heal, but a judicious adviser, who added much to its previous reputation as a model institution.

Resolved, That the loss of Dr. Sawyer is one equally great to the city of his residence and to the State at large, so many of whose citizens have had occasion to require his kindly skill.

Resolved, That the Rhode Island Medical Society mourns its deceased brother, whose mere acquaintance was a pleasure, and whom to know was to love. Gentle and yet decided, modest always, and wholly forgetful of self, learned in his special department of professional labor, and yet inferior to none as a general practitioner, his death leaves a void which time can but imperfectly fill.

Digitized by Google

Resolved, That the President and Secretary, in behalf of every member, tender to the bereaved widow and orphaned son of the deceased their sincere and heartfelt condolence, and their sense, not only of collective, but of personal, bereavement.

Resolved, That a committee be appointed by the Chair to attend the funeral of Dr. Sawyer in behalf of this Society, as an additional mark of sympathy and respect.

CORRESPONDENCE.

EXTRAUTERINE PREGNANCY CHANGED TO INTRAUTERINE BY FARADIZATION.

To the Editor of THE MEDICAL NEWS.

SIR: I have just read Dr. Garrigues's case of "Extrauterine Pregnancy Changed to Intrauterine by Means of Faradization," in your issue of the 12th inst., and would like to call attention to the fact, not mentioned by Dr. Garrigues, that in 1878 I reported a similar case to the New York Obstetrical Society (meeting June 11, 1878, see *Am. Journ. Obs.*, vol. xii. p. 330, 1879), in which the presumptive diagnosis of tubo-uterine pregnancy on the left side was made, with as much certainty as can exist in any such case, by the attending physician and myself, and in which the uterus was found empty, and spontaneous delivery of a three months' fœtus occurred on the next day.

In that report I spoke of McBurney's case (referred to by Garrigues), and also those of Poppel, Monteil, Pows, and Braxton Hicks (not mentioned by Garrigues), where, in a tubouterine gestation, the tubal orifice was so dilated as to allow the ovisac to protrude into the uterine cavity; and also the case of Lenox Hodge, who dilated the uterine orifice of the tube, and thus induced the expulsion of the fœtus through the natural passages.

As my case seems to have been overlooked, I hereby desire to recall it to the attention of the profession. The success of electricity in inducing contraction of the tube and propulsion of the fœtus into the uterine cavity was, I believe, accidental in McBurney's case, where the galvanic current was employed, and the object was to kill the fœtus in a supposed tubal pregnancy; the adaptation of faradism to the former purpose is ingenious, and, I think, worthy of trial; although success can be hoped for only when the uterine orifice of the tube and the uterine cavity itself are already dilated, when the ovisac protrudes into the uterine cavity, and when the circular fibres of the tube are well developed. In case of failure to produce the intrauterine propulsion of the ovum, the faradic current most probably will do no harm, since the destruction of the fœtus must be the next best result to be obtained from that treatment.

Respectfully,

PAUL F. MUNDÉ.

20 WEST 45TH STREET, NEW YORK,
December 19, 1885.

NEWS ITEMS.

HARVARD UNIVERSITY.—Dr. J. P. Reynolds has resigned the Professorship of Obstetrics in the Medical School of Harvard. It is stated that his course will be completed by Dr. William L. Richardson, the present Assistant Professor of Obstetrics in the School.

THE ALUMNI ASSOCIATION OF THE WOMAN'S HOSPITAL IN THE STATE OF NEW YORK will hold its first meeting at the New York Academy of Medicine, Wednesday, January 20, 1886. The order of exercises comprises a morning session from 9.30 A. M. to 1 P. M. After the address of the Chairman, Dr. James B. Hunter, papers will be read on The Treatment of Cancer of the Uterus; High Amputation *vs.* Total Extirpation, by Dr. William H. Baker, of Boston; on The Use of the Uterine Dilator in the Treatment of Dysmenorrhœa, and as an Aid in Intrauterine Therapeusis, by Dr. W. Gill Wylie, of New York; and on Local *vs.* General Treatment in Gynecology, by Dr. Andrew F. Currier, of New York.

An afternoon session will be held from 2 to 5 P. M., and papers will be read on The Non-surgical Treatment of Anterior Displacement, by Dr. P. H. Ingalls, of Hartford; A Brief Study of the Causes of Retroflexion and Prolapse of the Uterus, by Dr. George T. Harrison, of New York; and on The Exaggerated Importance of Minor Pelvic Inflammations, by Dr. Henry C. Coe, of New York. In the evening a business and social meeting will be held at 8 P. M.

THE ANNUAL ADDRESS BEFORE THE ACADEMY OF SURGERY OF PHILADELPHIA will be delivered by Dr. R. J. Levis, on Monday evening, January 4th, at 8 o'clock, at the Hall of the College of Physicians. Subject, "Impediments to the Progress of American Surgery."

DEATH OF MR. T. JOLLIFFE TUFNELL.—T. Jolliffe Tufnell's treatment of aneurism is known in all civilized countries, and it was a subject of which he made a lifelong study. Probably the last time he spoke in public was during the last session of the Academy of Medicine, when, consequent on a discussion which took place on a case of aneurism of the abdominal aorta, he recapitulated the most important points in the treatment which he believed to be essentially necessary. Mr. Tufnell was a Fellow of the Medico-Chirurgical Society of London, and a Fellow of the Academy of Medicine in Ireland. His contributions to medical literature included the following monographs: "The Treatment of Aneurism by Compression;" "The Successful Treatment of Internal Aneurism;" and "Stricture of the Rectum, with a new form of Bougie." He died on the 29th ult., at the age of sixty-seven, after a tedious illness.—*The Lancet*, Dec. 5, 1885.

LONDON ANTHROPOLOGICAL SOCIETY.—At a meeting of this Association, held on Tuesday week, Mr. Francis Galton, F.R.S., the President, exhibited, on behalf of Dr. Billings, of the United States Army, a collection of composite photographs of skulls. There were in all 20 photographs, forming four series, referring respectively to Sandwich Islanders, ancient Californians, Arapahoe Indians, and Witchitaw Indians, and each composite was the mean of six adult male skulls.—*Medical Times and Gazette* (London), Dec. 5, 1885.

THE OUTLOOK FOR THE CONGRESS.—The present Executive Committee has invited the former Committee to unite with it in its work of organization, but this invitation was declined by the Original Committee, except upon the condition that the present Executive Committee unite with them the Original Enlarged General Com-

Digitized by Google

mittee, and recommence the organization *de novo*. We are not informed whether the present Committee, which professes to have such a deep interest in the success of the Congress, has assented to this proposition. It seems to us that the plan proposed is the only harmonious solution of the differences which has been presented. This proposition gives a definite shape to the present muddle and enables all of the discordant elements to meet upon a common platform. A new Committee, consisting of the Original Committee of eight, of the Original Enlarged Committee, and of the present Executive Committee, unrestricted by former appointments, would be able to organize the Congress on an entirely new basis. The appointments of this Committee would be made from the entire profession, and would, no doubt, be given to men who best represent the American profession. The question of the "Code," the aspirations of ambitious office-seekers, the claims of Colleges and sections, and the demagogues in the profession would, no doubt, be relegated to the background. If it is upon the basis of this plan of organization that the present Executive Committee is warranted in announcing the success of the Congress, we believe its assurances will be verified. Upon any other basis we do not think the Congress will prove a success, and we shall believe that the assurances of the Executive Committee are but empty and hollow promises. We trust a solution of the present differences may be reached after the plan proposed, and that the profession will then join hands over the chasm and work for the success of the Congress of 1887.—*Maryland Medical Journal*, Dec. 19, 1885.

The Medical Record gives the following editorial note from the *St. Petersburg med. Wochenschrift* of Nov. 21: "The prospects of the next International Medical Congress, which was to meet in 1887 at Washington, have lately, in an unusual manner, been put in jeopardy. The original Organizing Committee, of which, as announced by us in previous communications, the well-known Surgeon-General of the U. S. Army was secretary-general, and to which the most distinguished American physicians belonged, has been retired. This was accomplished through the intrigues and hostility which developed at the last annual meeting in New Orleans. At this time a new committee was appointed under the presidency of a Dr. Shoemaker, of Philadelphia. This new organization committee contains but a few of the members of the previous committee, and is composed mostly of unknown and insignificant physicians, who inspire no confidence in their capacity for conducting the Congress. Under such circumstances any coöperation from foreign countries can hardly be expected."

OBITUARY RECORD.—DR. JOHN W. SAWYER, Superintendent of the Butler Hospital for the Insane, Providence, R. I., died at that institution, on the 14th inst., of blood poisoning, after an illness of only three days.

Dr. Sawyer was fifty-one years of age. He was formerly assistant physician at the same hospital, then under the superintendence of the late Dr. Isaac Ray. Subsequently he was Superintendent of the Madison Hospital for the Insane, in Wisconsin. At the close of the year 1866, upon the resignation of Dr. Ray, Dr. Sawyer became Superintendent of the Butler Hospital, which position he has since filled with marked ability and to the complete satisfaction of the Board of Trustees.

Wholly devoted to his special line of work, Dr. Sawyer rarely allowed himself any recreation or rest from the exacting duties of his position, but was persuaded to spend three months in Europe during the past summer. In appearance a quiet, unobtrusive man, he possessed the firmness and courage essential to success in his specialty, as an expert in which his opinion was much sought and esteemed, both in the medical profession at large and in courts of law.

—— At New York, on December 20, 1885, of pneumonia, after an illness of only two days, JOHN C. DRAPER, M.D., Professor of Chemistry and Physics in the Medical Department of the University of the City of New York.

Prof. Draper was born in Virginia, on March 31, 1835, and was the oldest son of the late Professor John H. Draper. He received his early education at the University of the City of New York, but in 1854 he left that college in his junior year to begin the study of medicine. Three years later he was graduated from the Medical Department of the University. In the last year of his school life he held the position of house physician and surgeon in Bellevue Hospital. The year following his graduation was spent in Europe, where he continued his medical studies. In December, 1858, he was made Professor of Analytical Chemistry in the University of the City of New York. He held the position for thirteen years. From 1860 to 1863 he was Professor of Chemistry in the Cooper Institute. During the Civil War Dr. Draper served for six months as a surgeon on General Ward's staff at Harper's Ferry, and was there at the time of its surrender. In 1863 he occupied for the first time the chair of Natural History in the College of the City of New York, which he has since held. In 1866 he became Professor of Chemistry in the Medical Department of the University.

As an author, Professor Draper was widely known. His original researches were made in the domain of chemistry, embracing all its branches, and always having a distinct bearing on the advancement of medical knowledge and practice. Professor Draper published his first book in 1865, it was a text-book on anatomy, physiology, and hygiene. He edited Scribner's *Year Book of Nature and Science* for 1872, and Draper's *Year Book of Nature and Science* the year following, and up to 1876; he also edited the department under this head in Scribner's *Monthly*. Besides a large number of scientific papers of considerable importance published subsequent to this, Professor Draper published, in 1882, a *Practical Laboratory Course in Chemistry*. His last work was a text-book of *Medical Physics*.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the NEWS *should be addressed to No. 1004 Walnut Street, Philadelphia.*
